CHEMICAL ABSTRACTS

Vol. 25. JANUARY 10, 1931 — May — No. 1

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Amber laboratory apparatus. C. PLONAIT AND A. EISENACH. *Chem. Fabrik* 1930, 422.—Test tubes, beakers and dishes made from pressed amber are almost completely resistant to concd. HF and to 50% KOH soln at water-bath temps. J. H. MOORE

The evaporation of large quantities of liquids in the laboratory. P. FUCHS *Chem. Fabrik* 1930, 421–2.—The methods of Weber, Hildebrandt and Selke (*C. A.* **24**, 1767, 3137, 3927) are criticized and Selke's method is improved by standing the supply bottle upright with a siphon extending to the bottom, the outer arm reaching nearly to the bottom of the evapg. dish which is placed so that the highest liquor level desired is slightly higher than the bottom of the bottle. The lower end of the open air tube in the 2nd hole in the stopper is set at the desired level of the liquor in the evapg. dish. J. H. MOORE

Laboratory electric stirrer. MANUEL LÓPEZ DOMINGUEZ AND JOSÉ PASCUAL VILA. *Anales soc. españ. fís. quím.* **28**, 1003–4(1930). E. M. S.

Sensitive safety valve for pumps. JOSÉ PASCUAL VILA. *Anales soc. españ. fís. quím.* **28**, 1005(1930). E. M. SYMMES

Acid-circulating pumps. F. W. ZERKOWER. *Chem. Fabrik* 1930, 434–6.—A brief review of the demands on such pumps and a description of Wegelin and Hübner's rubber-coated pump. J. H. MOORE

New type of shortened manometer. L. CHUDOZILOV. *Z. anal. Chem.* **82**, 68–9 (1930).—In work involving the distn. of fats, the inner surface of the manometer tube often becomes dirty because of contact with the distg. vapors and it is a tedious operation to clean and refill the tube. It is recommended, therefore, to replace the closed end of the usual short manometer tube with a glass stopcock which is connected with a funnel tube, bent a little to one side. It is easy to fill such a tube with Hg. W. T. H.

A micromanometer of high sensitivity. E. OWER. *Phil. Mag.* [7], **10**, 544–51 (1930).—For measuring low gas speeds, the capillary air bubble method is combined with the Chattock principle, in which the movement of the liquid levels under pressure is balanced by tilting the cups. Xylene is used as the manometric liquid. The instrument is sensitive to 0.00001 in. of H_2O and is capable of measuring speeds of 2 ft. per sec. with an accuracy of ±1%. ARTHUR FLEISCHER

A new viscometer. HANS SCHAFFER. *Petroleum Z.* **26**, *Motorenbetrieb und Maschinen-Schmierung*, No. 9, 4–8(1930).—A viscometer is described in which the liquid is discharged from the capillary in drops; the results are expressed in C. G. S. units. It consists of an insulated closed outer vessel which contains an indirect heating medium (H_2O, for temps. to 100°), stirrer, heating element and thermometers. An inner vessel contains the liquid being exaind. The capillary is of such size that 10 cc. of H_2O is discharged in 24.15 ± 1 sec. The loss of 10 cc. causes a drop in level of 1 mm. Successive runs with the same fluid can be made with const. hydrostatic head either by the return of the fluid withdrawn or by the application of 1 mm. of pressure for every 10 cc. (of H_2O) discharged. Pressure may also be applied to shorten the time of discharge. The range of viscosities from $\eta = 0.01$ to 10 may be detd. with the same capillary tube. The radius of the tube may be obtained either by measurement or by detg. the time of discharge of a known vol. of fluid with a known viscosity and calcg. the radius by means of the Poiseuille formula. For oils of low viscosity, a more accurate detn. is made when 20 cc. of oil is used instead of 10 cc. In this case the amt. of oil placed within the inner vessel is increased by 5 cc. so that the av. hydrostatic pressure is about the same as that when 10 cc. is used. For oils of very low viscosity, $\eta = 0.01$–0.03, a correction factor has to be applied which increases from 1.000 for $\eta = 0.0167$ to 1.073 for $\eta = 0.0176$. I. M. LAMBIE

Proposals for improvements in the apparatus for distillation in a high vacuum.

SIGMUND FRÄNKEL AND HERMANN MATHIS. *Biochem. Z.* 226, 157–61(1930).—App. is described. S. MORGULIS

An electrical method and instrument for measuring liquid consistency. CHAS. E. FAWKES. *Am. Paint & Varnish Mfrs.' Assoc.*, Circ. No. 370, 543–7; *Paint, Oil & Chem. Rev.* 90, No. 17, 90–1; *Oil, Paint & Drug Reporter* 118, No. 19, 62(1930).—A device for detg. the consistency of liquids consists of a disk-like rotor attached to the shaft of an elec. motor which is designed to be extremely sensitive to the load on the rotor. The counter e. m. f. and the field current vary in proportion to the load, the latter being indicated on a scale in arbitrary units which may be converted into poises. Consistencies covering a range of 10 to 1000 centipoises may be measured. G. G. SWARD

Cap for holding Gutzeit mercuric chloride paper. T. J. WARD. *Analyst* 55, 630 (1930).—A loose-fitting cap, which is dropped over the $HgCl_2$ paper, is prepd. from glass about 2 in. sq. which is coarsely ground on the lower surface. A circular cardboard rim is fastened to the glass The 14 g. cap is sufficiently heavy to prevent any gas escaping without coming in contact with the $HgCl_2$. W T. H.

Apparatus for supplying air under pressure. EDWARD M. HOSHALL. *J. Chem. Education* 7, 2674(1930). E. H.

Regulating the temperature of commercial furnaces. M. BÜCHTING AND C. HIMMLER. *Siemens Z.* 10, 551–9(1930).—19 illus. Review of modern practice. C. G. F.

Influence of annealing atmosphere, annealing temperature and protecting tube material upon the stability of platinum thermoelements. F. STABLEIN AND J. HINNÜBER. *Krupp. Monatsh.* 11, 245–51(1930).—Such strongly reducing gases as H, CO and illuminating gas are injurious to Pt materials in the presence of incandescent metals or silicates, causing contamination of the Pt alloys. The greatest contamination occurs in the presence of incandescent metallic protecting tubes, the effect of silicate or quartz tubes being much less. In addn. to a change in the thermal force there is also an increase in sp. resistance and an impairment of mech. properties Pure Pt wire is found to be more sensitive than a 10% Rh alloy. In practical pyrometry it is always advantageous to protect the Pt element with a tube of ceramic material, particularly if an external protecting tube of metal is used. K 60 mass is more gas tight at higher temps. than is quartz. H. STOERTZ

Thermostat of high degree of precision. IV. MENDELEEV. *Zhur. Prikladnoĭ Khim.* 3, 759–64(1930).—Accuracy within 0 001° is secured. V. KALICHEVSKY

Determination of the explosive limits of gases and gas mixtures (LÖFFLER) 24.

Rotary filter for various materials. FRANK W. YOUNG. U. S. 1,780,777, Nov. 4. Structural features.

Air filter. EMMETT F. ANNIS (to Harry C. Chappell). U. S. 1,779,458, Oct. 28. Structural features.

Air filter. E. H. SCHÄFER (to H. Wittemeier). Brit. 331,754, Oct. 27, 1928. Structural features.

Tubular filters for gases. F. AMME. Brit. 332,475, Oct. 12, 1928. Structural features.

Apparatus for removing dust from air or other gases by centrifugal force. BRITISH REMA MFG. CO., LTD., and P. HOWDEN. Brit. 332,405, July 18, 1929. Structural features.

Apparatus for separating dust and grit from air or other gases. SAMUEL N. CHEW (to Pneumatic Conveyance & Extraction (1929), Ltd.). U. S. 1,780,641, Nov. 4. Structural features.

Pressure filter for oil. CHARLES R. SHORT (to General Motors Research Corp.). U. S. 1,780,723, Nov. 4. A pressure-controlled by-pass between the inlet and outlet pipes serves to maintain an approx. uniform pressure differential between these pipes.

Pressure filter for filtering oil. CHARLES A. WINSLOW and ELBERT J. HALL. U. S. 1,780,663, Nov. 4.

Device for separating heavier impurities from oil, etc. EZEKIEL F. WHITE (to Grover V. Lassen). U. S. 1,780,774, Nov. 4. Structural features.

Apparatus for separating oil from gas. MYRON E. WAGNER. U. S. 1,780,101, Oct. 28. Structural features.

Tank and baffle system for separating oil and gas. MILLARD F. WATERS (to Smith Separator Co.). U. S. 1,779,023, Oct. 21. Structural features.

Trap for separating liquids from compressed gases. H. W. WILDISH. Brit. 331,704, July 18, 1929. Structural features of a baffle device.

Rotary separator for separating sludge from liqu AAGE NYROP. U. S. 1,780,655, Nov. 4. Structural features.

Device for removing pasty filter cakes from continuous drum filters. CLARK C. HERITAGE (to National Aniline & Chemical Co.). U. S. 1,781,389, Nov. 11. Structural features.

Filtering apparatus with filter plates passing successively to and from a filtering zone. ROBERT S. BUTLER (to Southwestern Engineering Corp.). U. S. 1,780,905, Nov. 11. Structural features.

Crucible. AMERICAN MACHINE & FOUNDRY Co. Brit. 331,399, July 12, 1929. Various details are described of the manuf. of crucibles with an outer shell and a compressed non-corrodible lining such as "Amaloy" comprising Pb contg. Sn and P, the lining metal being poured into the shell while rotating the latter on its axis.

Gas calorimeter. JAMES P. FISHER (to Burgess-Parr Co.). U. S. 1,779,373, Oct. 21. Structural features.

Gas calorimeter. SAMUEL W. PARR (to Burgess-Parr Co.). U. S. 1,778,958, Oct. 21. Structural details.

Gas calorimeters. SAMUEL W. PARR (to Burgess-Parr Co.). U. S. 1,779,371-2, Oct. 21. Structural features.

Direct-reading photometer. SAMUEL WEIN (to Radiovision Corp.). U. S. 1,779,574, Oct. 28. Structural features.

Surface condenser. ALBIN J. NOTT. U. S. 1,780,837, Nov. 4. Structural features.

Surface condenser suitable for steam condensation. RAYMOND N. EHRHART (to Elliott Co.). U. S. 1,780,781, Nov. 4.

Viscometer. FRANZ P. ZIMMERLI (to Automatic Appliance Co.). U. S. reissue 17,841, Oct. 21. Reissue of original pat. No. 1,557,517 (*C. A.* 20, 2).

Viscometer with radio tubes and circuits influenced by a falling ball in the liquid tested. ERNEST M. SYMMES (to Hercules Powder Co.). U. S. 1,780,952, Nov. 11. The app. is especially suitable for use with opaque liquids.

Röntgen-ray apparatus. E. S. HUMPHREYS. Brit. 331,999, May 27, 1929. Structural features.

Photoelectric cells. GENERAL ELECTRIC Co., LTD., and N. R. CAMPBELL. Brit. 332,002, May 27, 1929. Photoelec. cathodes consisting of a thin film of Cs or Rb on a support of another metal such as Ag oxidized before the deposition of the film are sensitized, particularly to white light and to light at or beyond the red end of the spectrum, by a glow discharge through a rare gas such as He, which may be left in the cell so that the sensitivity of the cathode (likely to decrease during the early life of the cell) may be restored by a glow discharge (or automatically if the cell operates with considerable ionization). Various details of procedure are described. Cf. *C. A.* 24, 2921.

Thermionic valves. K. W. DAUMANN. Brit. 331,250, March 25, 1929. Various details are described of thermionic valves such as those used for rectifying high voltages supplied to x-ray tubes and having an outer insulating cylinder which may be formed of lead-glass or of artificial resin with addns. of Pb salts or $BaSO_4$ and is capable of absorbing x-rays produced in the valve.

Thermionic valves. F. A. GOULDING and S. F. GAME. Brit. 331,231, July 23, 1929. Various details of structure and manuf. are described.

Vacuum chambers. AMERICAN THERMOS BOTTLE Co. Brit. 331,493, Jan. 19, 1929. The inner surfaces of a vacuum chamber are coated by the decompn. of a volatile metallic compd. such as Ni carbonyl, Fe carbonyl, $NiCl_2$ or the chlorides of Al, Sb, Cu, Ti, Bi and Sn, as by heating in the presence of a reducing agent such as H or CO. Various details of procedure are given.

Apparatus for extracting moisture from air by a spiral wire gauze. FREDERICK R. HALL. U. S. 1,780,156, Nov. 4. Structural features.

Hygrometric filament apparatus for determining moisture content of sheet materials. ALBERT ALLEN (to Atlantic Precision Instrument Co.). U. S. 1,781,153, Nov. 11. Structural features.

Spray nozzle apparatus for humidifying air or other gases. COOLING and AIR CONDITIONING CORP. Brit. 331,218-9, March 25, 1929. Structural features.

Spray-cooling tower for liquids such as water. CHESTER R. KRANZ (to Binks Mfg. Co.). U. S. 1,780,020, Oct. 28. Structural features.

Cooling tower for treating showered liquid with air streams. J. M. SEYMOUR. Brit. 331,427, Aug. 28, 1929.

us for emulsifying oils, water and dispersing arsenic, etc., together by use of

concentric spraying nozzles. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. B. F. F. CLARKE. Brit. 331,928, April 12, 1929. Structural features.

Apparatus for emulsification of oils and water or other materials under successive oscillations of pressure from a piston. VINCENT G. WALSH. U. S. 1,780,853, Nov. 4. Structural features.

Devices for taking samples of liquid from different levels in tank cars, etc. JOHN M. MAYHALL and HOWARD C. MORRISON. U. S. 1,780,597–8, Nov. 4. Devices are described adapted also for simultaneously determining domage and ullage while taking samples.

Rectifying tube. JACQUES RISLER (to Risler Corp. of America). U. S. 1,780,504, Nov. 4. Various structural details are described relative to evacuated tubes with hollow cathodes contg. an alk. earth salt.

Column and plate type of apparatus for distillation and rectification. ADOLF MESSER. U. S. 1,780,563, Nov. 4. Structural features.

Meter for recording flow of ionized gas. A. E. BLAKE (to Humphreys & Glasgow, Ltd.). Brit. 331,439, Oct. 18, 1928. Structural and elec. features.

Apparatus for detecting inflammable gas mixtures. H. T. RINGROSE. Brit. 331,711, July 24, 1929. Combustion of an inflammable gas mixt. in a porous vessel causes collapse of a diaphragm and operation of an elec. lamp warning circuit. Various details of app. are described. Cf. *C. A.* **24**, 2606.

Centrifugal gas-cleaning device. E. J. BRADY (to Humphreys & Glasgow, Ltd.). Brit. 331,755, Oct. 26, 1928. Structural features.

Liquid and gas contact tower suitable for scrubbing gas. FREDERICK H. WAGNER. (to Bartlett Hayward Co.). U. S. 1,780,255, Nov. 4. Structural features.

Gas-washing apparatus with stationary or oscillating brushes. S. G. WATSON, D. M. HENSHAW and W. C. HOLMES & Co., LTD. Brit. 331,818, April 3, 1929. Structural features.

Baffle and spray apparatus for washing gases. PNEUMATIC CONVEYANCE & EXTRACTION, LTD., and W. A. SMITH. Brit. 332,283, April 18, 1929. Structural features.

Rotating brush apparatus for washing gases, etc. S. G. WATSON, D. M. HENSHAW and W. C. HOLMES & Co., LTD. Brit. 331,592, April 3, 1929. Structural features.

Container for storage and transport of liquefied gases. SCHULIM BRAUNSTEIN. U. S. 1,781,048, Nov. 11. Structural features.

Apparatus and procedure for liquefying solid carbon dioxide. MASCHINENFABRIK ESSLINGEN and J. STOFFELS. Brit. 331,750, Sept. 3, 1929. Various details are described.

Mixing and stirring apparatus for effecting chemical reactions, etc. CELANESE CORP. OF AMERICA and BRITISH CELANESE, LTD. Brit. 331,606, April 15, 1929. Structural features.

Apparatus for agitating materials in tanks. ARTHUR W. BULL (to Dorr Co.). U. S. 1,780,551, Nov. 4. Structural features.

Apparatus for agitating, mixing and circulating detergents or other liquids in tanks. THOMAS O'FARRELL (to Russell C. Bloomfield). U. S. 1,780,360, Nov. 4. Structural features.

Hydraulic molding press. LESLIE S. HUBBERT (to Hydraulic Press Mfg. Co.). U. S. 1,778,803, Oct. 21. Structural features.

Hardness tester of the pendulum type. EMIL VON LEESEN. U. S. 1,781,615, Nov. 11. Structural features.

Apparatus for drying coal, grain, ore, wood pulp, etc. JOHAN D. ULLGREN (to Aktiebolaget Karlstads Mekaniska Verkstad). U. S. 1,779,571, Oct. 28. Structural features of app. for agitating the material in contact with drying gases.

Acid jar with a clamping cover. REYNOLD W. PETERSON. U. S. 1,780,534, Nov. 4. Structural features.

Recording photometric apparatus. GEARY A. LONG, JR. (to General Elec. Co.). U. S. 1,779,324, Oct. 21.

Annealing box. HERMAN A. FISHER. U. S. 1,778,798, Oct. 21. Structural features.

Oven suitable for treating coated or lithographed tin sheets. HENRY A. DREFFEIN. U. S. 1,779,622, Oct. 28. Structural features.

Annular tunnel kiln. ARTHUR M. DUCKHAM. U. S. 1,780,119, Oct. 28.

Shaft furnace or kiln fired with gas, oil or powdered fuel. C. F. PRIEST. Brit. 332,037, June 25, 1929. Structural features.

Side-wall tuyère furnace. JACOB SPERLING (to Westinghouse Elec. & Mfg. Co.). U. S. 1,779,861, Oct. 28.

Rotary furnace for low-temperature distillations. KOHLENVEREDLUNG A.-G. and C. GEISSEN. Brit. 331,673, June 17, 1929. Various details are described of a special brickwork filling, etc.

Furnace regenerator. BABCOCK & WILCOX, LTD., and C. H. DAVY. Brit. 331,977, May 7, 1929.

Combustion system for boiler furnaces, etc. A. J. WHEELER. Brit. 331,183, Feb. 19, 1929. A higher temp. flame from supplementary burners impinges on fuel and air from a main burner at a point near its entrance into the furnace. Various details of construction and operation are described.

Automatic temperature-recording apparatus suitable for use with boiler furnaces. FREDERICK D. POTTER (to Combustion Control Co.). U. S. 1,779,619, Oct. 28.

Gas seal for furnaces. JAMES W. FLYNT (to Fuller Lehigh Co.). U. S. 1,779,120, Oct. 21. Structural features.

Gas burner. H. FRISCHKORN. Brit. 332,063, July 19, 1929.

Gas burner. JOHN L. MANDEVILLE (to J. B. Colt Co.). U. S. 1,780,596, Nov. 4.

Gas burner. RICHARD THURM (Baker Perkins Co., Inc.). U. S. 1,778,839, Oct. 21.

Gas burner. JOHN S. ZINK. U. S. 1,781,623, Nov. 11.

Electric liquid heaters. ANTON FAZEKAS. U. S. 1,779,667–8, Oct. 28. Structural features.

Electric water heater. MICHAEL S. GAZELLE. U. S. 1,779,696, Oct. 28. Structural features.

Electric water heater. L. P. HAUSSAUER. Brit. 332,401, July 16, 1929. Structural features.

Electric immersion water heater. WM. J. HANDLEY (to Handley-Brown Heater Co.). U. S. 1,779,128, Oct. 21. Structural features and details of operation of a storage continuous-supply heater.

Apparatus for heating water by electric heating elements. EMIL F. HOLINGER (to Hudson Electrical Heating Corp.). U. S. 1,779,937, Oct. 28. Structural features.

Apparatus for heating water or other liquids by waste gases such as those from Cowper heaters of a blast furnace. SUPERHEATER CO., LTD., and COMPAGNIE DES SURCHAUFFEURS. Brit. 332,274, April 16, 1929. Structural features.

Apparatus suitable for heating air by hot flue gases. WM. A. JONES (to Babcock & WILCOX Co.). U. S. 1,780,301, Nov. 4. Structural features.

Heat-exchange apparatus. HEENAN & FROUDE, LTD., and G. H. WALKER. Brit. 331,602, Jan. 10, 1930. Structural features.

Tubular heat-exchange apparatus. M. PAYNE. Brit. 331,392, July 4, 1929. Structural features.

Heat-exchange apparatus for heating air or other gases. W. E. KOCHS & CO., LTD., and H. FÖGE. Brit. 332,280, April 17, 1929. Structural features.

Heat-exchange device suitable for heating air by hot flue gases. DAVID S. JACOBUS and WM. A. JONES (to Babcock & Wilcox Co.). U. S. 1,780,300, Nov. 4. Structural features.

Heat-exchange apparatus suitable for heating air with flue gases, etc. CHARLES B. GRADY (to Metropolitan Engineering Corp.). U. S. 1,779,538, Oct. 28. Structural features.

Heat-exchange apparatus suitable for heating air by hot waste gases. ARCHIBALD H. DAVIS, JR. (to Shaw-Perkins Mfg. Co.). U. S. 1,780,294, Nov. 4. Structural features.

Heat-exchange apparatus with gills and baffles. H. JUNKERS. Brit. 332,455, Oct. 26, 1928. Structural details.

Heat-exchange apparatus with parallel sheet metal plates. J. M. HARRISON. Brit. 331,982, May 13, 1929. Structural features.

Heat-exchange apparatus with pipes, headers and an electric heater. G. KRÄNZLEIN and SAMESREUTHER & CO., GES. Brit. 331,910, April 9, 1929. Structural features.

Lining stills with rubber. IMPERIAL CHEMICAL INDUSTRIES, LTD., and F. H BRAMWELL. Brit. 331,838, Jan. 9, 1929. Sepn. of a rubber lining in stills or reaction chambers is prevented by forming the vessel with a double wall, the inner wall being perforated while there is maintained in the space between the walls a lower pressure than that within the app.

Apparatus for deodorizing hair, feathers, etc., with ozone. AMERICAN HAIR & FELT CO. Brit. 331,845, April 4, 1929. Structural features.

Thermostatic and magnetic circuit-breaking device. CHARLES A. MARTIN. U. S. 1,780,202, Nov. 4. Structural features.

Thermostatic control device for electric circuits. LAWRENCE E. KOCH and HENRY F. DEVER (to Time-O-Stat Controls Co.). U. S. 1,780,302, Nov. 4. Structural features.

Thermostatic control for electric circuits. HENRY G. LEUPOLD (to Electrical Laboratories, Inc.). U. S. 1,780,758, Nov. 4. Structural features.

Thermostatic control device for electric heaters. SAMUEL M. CARMEAN and JAMES H. CARMEAN. U. S. 1,780,462, Nov. 4. Structural features.

Thermostatic control device for electric heating appliances. PETER A. PETERSON. U. S. 1,780,631, Nov. 4. Structural features.

Thermostatic control device for electric heating pads. WALTER K. TAVENDER. U. S. 1,779,149, Oct. 21. Structural features.

Thermostatic valve for supply of gas to burners. JOHN H. GRAYSON. U. S. 1,781,328, Nov. 11. Structural features.

Fluid-pressure-operated thermostatic electric switches. EDWARD L. MAYO (formerly Edward J. Levy). U. S. 1,781,287-8-9, Nov. 11.

Thermostatic control device for regulating the feeding of arc electrodes of arc lamps. MARTIN L. PATTERSON (to Sperry Gyroscope Co.). U. S. 1,778,770, Oct. 21. Structural features.

Thermostatic device for fire-alarm systems, etc. LOUIS J. J. B. CHENEAU. U. S. 1,781,630, Nov. 11. Structural features.

2—GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

Louis Munroe Dennis. A. W. BROWNE. *Ind. Eng. Chem.* **22**, 1257–8(1930).—A biographical sketch with portrait. E. C. K.

Cinchona, 1630-1930. P. VAN DER WIELEN. *Pharm. Weekblad* **67**, 1117–21 (1930).—Extracts from old documents relating to the early history of cinchona are briefly discussed, prefatory to the complete text (pp. 1123–1220) of "Zuma, or the Discovery of Cinchona Bark," a drama in 4 acts by Jan de Quack published in Amsterdam in 1819. A. W. DOX

The methodology of scientific research. HENRY M. LE CHATELIER. *J. Chem. Education* **7**, 2584–9(1930). E. H.

Modern physics—a survey. I, II, III. SAUL DUSHMAN. *J. Chem. Education* **7**, 1778–87, 2077–87, 2655–63(1930). E. H.

Grade-school methods an asset to the chemistry teacher. BRUCE F. LAMONT. *J. Chem. Education* **7**, 2701–3(1930). E. H.

The use of models in teaching polarity. SIDNEY J. FRENCH. *J. Chem. Education* **7**, 2687–91(1930). E. H.

A demonstration of changes in ionic equilibria during chemical reactions. HOSMER W. STONE. *J. Chem. Education* **7**, 2722–4(1930).—A lecture expt. E. H.

Alchemy: Folly or wisdom? RALPH E. OESPER. *J. Chem. Education* **7**, 2664–74 (1930). E. H.

Ozone and atomic oxygen in the upper atmosphere. S. CHAPMAN. *Phil. Mag.* [7], **10**, 369–83(1930); cf. *Memoirs Roy. Meteor. Soc.* **3**, 103–25(1930); and *C. A.* **24**, 5547.—Theoretical and speculative considerations of the O_3 and O concns. at heights greater than 50 km. show that the O_3 concn. diminishes rapidly at heights above the level of max. concn. and especially above the level at which convective mixing is important; the O concn. increases upward till it exceeds the O_2 concn. A. F.

Graphical methods for calculating constants. I. New methods of determining the order of a reaction. M. CRESPI. *Anales soc. espan. fis. quim.* **28**, 844–70(1930).—From the equation $\frac{dx}{dt} \quad n \log (a - x) + \log k$ a method is deduced to det. n and k, which are called angular coeffs. They can be generalized by the equation $\frac{dx}{dt} = k(a -$

$x)^\alpha(b-x)^\beta(c-x)^\gamma$ ..... From the equation $\log \frac{t''_p}{t'_p} = (n-1)\log \frac{a'}{a''}$ another method is deduced to det n by a series of measurements called partial concns. The asymptotic equation $y^{n-1}\theta = a^{n-1}$, is established for these chem. processes, and by making $\frac{y_1}{y_2} = \frac{y_2}{y_3} = \frac{y_3}{y_4} = \ldots = r$ there is obtained $\frac{\theta_3-\theta_2}{\theta_2-\theta_1} = \frac{\theta_4-\theta_3}{\theta_3-\theta_2} = \ldots = r^{n-1}$, r being a const. greater than 1. A new method called geometric progression is then deduced. Based on a property of tangents and secants of an equilateral hyperbole, there is shown a method of detg. whether a reaction is bimol. E. M. SYMMES

Determination of surface tension by lifting of large disks. J. E. VERSCHAFFELT. *Bull. sci. acad. roy. Belg.* [5], **16**, 26–34(1930).—Previously (*C. A.* **23**, 4119) a method was described for detg. surface tension by the lifting of disks from a liquid surface. For large disks the lifting force F equals $\pi r^2\delta g a\sqrt{2}f(a/r)$. The function $f(a/r)$ with a the "specific const." (a^2 is capillary const., r the radius of the disk) can be developed to $1 + (ma/r) + n(a/r)^2$, in which $m = -1/6\sqrt{2} = -0.2357$ and n is approx. 0.9. The present paper reports measurements for more accurate data on n in order to make the method of disk lifting an abs. detn. for surface tension. Circular glass disks were used of diam. 4, 6, 8 and 10 cm., carefully ground flat with beveled edges, 2.5 cm. thick. A Cu disk with vertical glass rod and hook attached was used for hanging the disk, the latter being well balanced. F of the order of 20 to 35 g. for the largest disks was measured (0.05% accuracy). Measurements were made on C_6H_6, $PhNO_2$, $PhNH_2$ and CCl_4 between 10° and 20°. The results were for the resp. liquids $a = 0.2585$, 0.2717, 0.2948 and 0.1848 (all values derived previously relative to water of $a = 0.3858$). $f(a/r)$ varies from 0.989 to 0.982 (CCl_4 was abnormal). The av. value of n is 0.86 (0.9999 for A, the first member of the a/r series) and the corrected values of $a = 0.2583$, 0.2718, 0.2945 and 0.1849 for the 4 liquids (20°, air boundary). The capillary constant a^2 for water at a point where $g = 980.6$ is corrected to 0.1489. B. J. C. VAN DER HOEVEN

Dark-field microscopy with polygonal illumination. CH. SPIERER. *Kolloid-Z.* **53**, 88–90(1930); cf. *C. A.* **24**, 3138.—The previously described app. revealed with greatest clearness the micelle fibrous structure of cellulose membranes of various plants. ARTHUR FLEISCHER

A study of the character of purified platinum contacts. R. HOLM AND R. STÖRMER. *Wiss. Veröffentlich. Siemens-Konzern* **9**, 323–30(1930).—Measurements of contact resistances at various temps. and pressures show agreement with resistances calcd. by formulas. F. D. ROSSINI

Abundance of the elements and the existence of a new periodic system. R. A. SONDER. *Z. anorg. allgem. Chem.* **192**, 257–85(1930).—A new system of the elements is based on a periodicity in the at. nos. of the elements arranged on the basis of abundance in the earth. A curve showing abundance of distribution exhibits a series of maxima for the elements O, Si, Ca, Fe, Sr, Sn, Ba, W, Pb, U with at. nos. of 8, 14, 20, 26, 38, 50, 56, 74, 82 and 92, resp., the difference between individual members being 6 or a multiple of 6 in nearly every case. The paper includes a complete discussion of this system and of the curves in which abundance of distribution is plotted against at. no. Elements with even at. no. are invariably more abundant than elements of odd at. no. immediately preceding and following them. Many of the discrepancies in this system are explained by inaccurate information regarding the abundance of the elements in question. H. S.

Photosensitivity and the periodic system of the elements. T. PAVOLINI. *Industria chimica* **5**, 1107–15(1930).—Among the 92 elements in the periodic system there are about 40 that exhibit photosensitivity of one form or another. They may be classified as follows: elements showing photoallotropy—O, P, As, Sb; photoelectricity—Se; photolysis—Cu, Ag, Au, Hg, Tl, Pb, Bi, halogens; photoreduction—Ti, V, Cr, Mn, Fe, Co, Se, Zr, Cb, Mo, Ru, Pd, Te, Ce, Ta, W, Os, Ir, Pt, U; photosynthesis and photoisomerism, as well as photolysis and photoreduction—C. Examples and references are given. A. W. CONTIERI

Mass of the normal liter and compressibility of ammonia gas. New revision of the atomic weight of nitrogen. E. MOLES AND T. BATUECAS. *Anales soc. espaü. fis. quím.* **28**, 871–94(1930); cf. *C. A.* **24**, 1264.—Revision of the mass of the normal l. of NH_3 gas was carried out with NH_3 from $(NH_4OOC)_2 + KOH$, with synthetic NH_3 and with NH_3 from hydrolysis of Mg_3N_2. Drying the NH_3 is best done by P_2O_5 sublimed in a current of very pure O_2. A total of 31 detns. of the wt. of the normal l. gave $L_0 = 0.77169 \pm 0.00005$, about 0.001 greater than the previously accepted value but identical with that of Leduc, after correcting for adsorption. At less than atm. pressure $L_{0.5087} = 0.76772$, $L_{0.4000} = 0.76585$, $L_{0.2333} = 0.76383$. Deviation from the Avogadro law is 1 +

$\lambda = 1.01552$. From calcn. of the mol. wt. of NH_3 that of N = 14.009, a good agreement with the accepted value and identical with that found by Moles and Clavera. NH_3, like other condensible gases, obeys the laws of limit d., as found by Batuecas and others for other gases. The assumed anomaly of NH_3 was not found. E. M. SYMMES

The boiling point of water as a function of the pressure. A. ZMACZYNSKI AND A. BONHOURE. *J. phys. radium* [7], **1**, 285–91(1930).—See *C. A.* **24**, 2929. E. C. K.

Dielectric constant of bromine vapor. ARTHUR BRAMLEY. *J. Franklin Inst.* **210**, 421–3(1930); cf. *C. A.* **21**, 1218.—The dielec. const. of Br vapor was measured by a d. c. bridge method with the aid of an electrometer. The results at 28.5° varied linearly with the pressure and were independent of the applied elec. field. The data for the dielec. const. D measured at 28.5° gave the value $D = 1.0047 \pm .0003$, reduced to 760 mm. and 0°. The values of the const. at higher temps. were considerably higher, and also depended on the voltage applied between the condenser plates. The theory that at the higher temps. the mols. were raised from the normal state to a higher energy level by heat radiation explains the results satisfactorily. This assumption leads to an expression for the dielec. const. D, at temp T and pressure P, of the form $(D-1)/(D+2) = P\sum_{s=1}^{\infty}\sum_{p=1}^{\infty} B_{sp} e^{\frac{h\nu(sp)}{kt}} \lambda^2 sp$, where B_{sp} is proportional to the transition probability of a transition from the state s to some other state p, and $\nu(sp)$ is the absorption frequency assocd. with this transition, a neg. no. in absorption of energy. LOUISE KELLEY

Electric moments of several molecules. HORST MÜLLER AND H. SACK. *Physik. Z.* **31**, 815–22(1930).—The results of detns. in benzene as the non-polar solvent are: ($\times 10^{18}$) C_6H_5Br 1.52, C_6H_5Cl 1.57, CH_2Cl_2 1.55, $CHCl_3$ 1.18, MeOAc 1.75, EtOAc 1.81, PrOAc 1.86, BuOAc 1.85, isobutyl acetate 1.87, AmOAc (mixt. of isomers) 1.91, *sec*-octyl acetate 1.93, benzyl acetate 1.80, cetyl alc. 1.66, 9-bromoanthracene 1.50, *trans*-dichloroethylene 0.70, *cis*-dichloroethylene 1.74, $CHBr_3$ 0.99, CHI_3 0.95, CH_2Br_2 1.38 and CH_2I_2 1.10. In hexane, the moments detd. are CHI_3 1.0, CH_2Br_2 1.42 and CH_2I_2 1.14. ARTHUR FLEISCHER

New studies on electric moments. O. HASSEL. *Z. Elektrochem.* **36**, 735–7(1930); cf. *C. A.* **24**, 4435, 4673.—Elec. moments were measured for soln in C_6H_6 of mixts. of $CHCl_3$ (0.3–1.5 *M*) and PhCl (0.3–2.0 *M*) and of Et_2O (0.5–2.5 *M*) + $CHCl_3$ (0.5 – 2.5 *M*). Results are also given for dil. solns. of C_6H_6, PhMe, $CHCl_3$, $PhNH_2$ in Me_2CO; C_6H_6, PhMe, $CHCl_3$, PhCl in $PhNO_2$; C_6H_6, PhMe, $CHCl_3$ in PhCl; C_6H_6, PhMe, $CHCl_3$ in PhCOMe; $H_2O + Et_2O$; $C_6H_6 + CHCl_3$; C_6H_6, PhMe in paraldehyde, C_6H_6, $CHCl_3$ in Et_2O; C_6H_6, Et_2O in $CHCl_3$; Et_2O + *p*-$C_6H_4(OH)_2$. Measurements at 18°, 40° and 60° show no temp. coeff. for *p*-$C_6H_4(OMe)_2$, *p*-$C_6H_4(OEt)_2$, PhCN, PhCHOHBz. Results are given at 18° for *p*-$ClC_6H_4NH_2$, *p*-$CNC_6H_4NO_2$, PhNC, PhNCO, PhCHOHCHOHPh and isohydrobenzoin. G. M. MURPHY

The statistical theory of para- and dia-magnetism. EMRYS HOWELLS. *Phil. Mag.* [7], **10**, 698–711(1930).—A generalization of Langevin's statistical theory of magnetization is developed somewhat along the lines laid down by Gans by assuming that the magnetization of mols. arises from their angular motions and is influenced by the magnetic force. ARTHUR FLEISCHER

The relations of the magnetic and thermal constants of ferromagnetic substances. J. R. ASHWORTH. *Phil. Mag.* [7], **10**, 681–94(1930). The relations of the 3 fundamental magnetic consts. are derived and discussed for Fe, Co, Ni, Heusler's alloy and magnetite. ARTHUR FLEISCHER

Magnetic change in resistance and Hall effect in cuprous oxide, with and without illumination. OTTO VON AUWERS. *Wiss. Veroffentlich. Siemens-Konzern* **9**, 294–9 (1930).—The Hall effect and magnetic change in resistance were investigated for strips of Cu_2O approx. 60 × 15 × 0.5 mm. for fields up to approx. 20,000 gausses. The Hall effect was found to be very large and almost uninfluenced by illumination. On the other hand, the effect of a magnetic field on the resistance was found to be vanishingly small but the effect of illumination is very large. The bearing of these results on the question of an inner photoelec. effect in a semi-conductor is discussed. W. W. S.

Influence of a magnetic field on the passivity of metals. U. SBORGI AND A. BORGIA. *Gazz. chim. ital.* **60**, 449–68(1930). Previous papers (cf. *C. A.* **19**, 3204–5; *C. A.* **21**, 852) set forth certain relations between the electronic structure of the atoms of transition elements of the periodic system and the passivity of the metals. These relations and the facts that the transition elements are generally paramagnetic (sometimes ferromagnetic), and that the magnetic properties depend upon some characteristic of the electronic structure, point to a connection between magnetic properties and passivity. It is now shown experimentally that passivity may be interpreted electronically (cf. S.,

Atti soc. Toscana sci. nat. 37). The *app.* is described in detail. It was possible to obtain intense magnetization of much greater duration than with previous methods, which permitted obtaining polarization curves and time-potential curves at a const. c. d. These latter are not only clearer than the polarization curves but also are more reproducible. With Fe and with Co (in 15% H_2SO_4) a distinct activating effect of magnetization was established. The Co, however, contained Fe, Cu and Ni as impurities. With Ni the effect was much smaller, and the results varied with the samples of Ni tested.
C. C. DAVIS

Dielectric losses and electric dipole moment in transformer oil. L. S. ORNSTEIN AND G. J. D. J. WILLEMSE. *Z. tech. Physik* 11, 345–9(1930); cf. *C. A.* 22, 3982.—The dielec. losses of transformer oil remaining after the cond. has been reduced by "stabilization" (l. c.) were studied. On the assumption that oils contain a considerable no. of dipoles, the *Kerr effect* was measured. Light from an arc or W ribbon lamp was passed through an optical system including an elec. condenser of 2 parallel plates with oil in between, placed between 2 crossed nicols, the plane of polarization being at 45° with the condenser plates. The condensers were between 1 and 20 cm. long and the plate distance was 4 mm. The Kerr effect for the oil was compared with that of CS_2 (const. = 100). A. c. or d. c. was used on the condenser. Furthermore the temp. coeff. of the dielec. const. was detd. for the oils between 17° and 150° by interference tone method; the dielec. losses were measured for low and high frequencies, 0, 50, 300, 500 and 6.10^4 to 3.10^6, resp. The oils used for these expts. were I a petroleum distillate, II the Edeleanu ext. of I, *i. e.*, the aromatics removable by SO_2 extn., III the "Edeleanu raffinate" of I, *i. e.*, the remaining oil after SO_2 extn., IV the same as III but extd. with fuming H_2SO_4, removing SO_3 aromatics. This oil is purely aliphatic and naphthenic. Other samples were prepd. by removal of org. acids from the former samples and by redistn. to bring them to equal viscosity. Two samples of liquid paraffin were also examd. The Kerr const. appeared to be equal for stabilized and non-stabilized oil as expected; it is stronger for I (53) than for III (18) and is therefore attributed to dipoles in the SO_2 ext. II (96). The sample IV had only 1.7 const. The same results were obtained from the redistd. samples with the difference only that higher viscosity gives a slightly decreased Kerr effect. The liquid paraffins had a const. of 1.4. For the temp. coeff. of dielec. const. and for dielec. losses a general trend was found running parallel to that of the Kerr const. qualitatively; it confirms the authors' opinion that dipoles in the oil are the cause of those losses which vary with the frequency. All values detd. are tabulated, including viscosity η, dielec. const. ϵ_{15}, $\epsilon_{15} - \epsilon_{100}$, $\eta\sigma$ (σ is cond.), d. and $(V_{300} - V_{50})/E^2\eta$ (V_{300} is dielec. loss for 300 frequency, E potential). In particular the latter quality, which can be considered as a fair measure for the hysteresis losses, corresponds almost quantitatively with the Kerr const.
B. J. C. VAN DER HOEVEN

Behavior of atomic hydrogen. II. Behavior of pentane toward ultra-violet light and of its polymerization products toward oxygen. Influence of mercury. ALFONS KLEMENC AND FRANZ PATAT. *Z. physik. Chem.*, Abt. A, 149, 449–64(1930).—When pentane is radiated, decompn. and polymerization take place even in the absence of Hg. The reaction $CO + H_2 \longrightarrow HCHO$ does not occur in the absence of Hg. In the presence of ultra-violet light, the polymerization products of pentane take up O. The latter is given off as CO and CO_2, while the C chain breaks and light hydrocarbons (methane) are given off. Light from a Hg arc causes oxidation of CO and H_2, without the influence of Hg. The splitting-off of H_2 from pentane and the formation of water are both sensitized by Hg, while the combustion of CO is not.
FRANK URBAN

The determination of molecular structure by the diffraction of electrons by a stream of vapor. H. MARK AND R. WIERL. *Z. Elektrochem.* 36, 675–6(1930).—Using 40-kv. electrons, the authors were able to get a photograph of the diffraction in CCl_4 vapor in 0.1 sec. From equations previously developed (cf. *C. A.* 24, 2948) and photographs, it was possible to calc. the at. radii: C = 0.8 A. U., Si = 1.2 A. U. and Ti = 1.5 A. U., which agree with Goldschmidt's values. By use of an aliphatic compd. like cyclopentane, the distance between C atoms = 1.5 A. U., while for aromatic compds. like benzene and cyclohexane, the distance = 1.4 A. U. Measurements on 1,5-dichloropentane showed that the mol. is not distorted; the distortion of the benzene ring in the di- and tri-chlorobenzenes is being investigated. Even ordinarily solid compds. can be investigated by this method, if the mol. vapor oven is used for vaporization.

The theory of anisotropic liquids. XII. The relations between molecular structure and density fluctuations. C. W. OSSEN. *Arkiv. Mat. Astron. Fysik* **22A**, No. 12, 20 pp.(1930); cf. *C. A.* **24**, 764.—A math. theory is developed by using the assumption that the dependence of the d. on the space coördinates is already valid in the action sphere of the mol. The theory overcomes the difficulties in the previous theory of nucleus and convergence point. ARTHUR FLEISCHER

Internal structure of solid oxygen-containing salts at high temperatures. I. General theoretical foundation. WILHELM JANDER. *Z. anorg. allgem. Chem.* **192**, 286–94(1930).—Solid O-contg. salts occur in 4 fundamental types. In the first the structure is that of a pure ion lattice, the lattice positions being occupied by the metallic ion M and the element π (π = Cl, S, W, Mo, N, P, Cb, C, Si, Al, etc.), the O surrounding π to form a complex ion πO_4. In the second type of structure the lattice positions are occupied by M, R and O, the interval M to O being equal or closely similar to the interval R to O. The third type of structure is characterized by a lattice built up of neutral mols. as in the org. compds., while in the 4th type the double oxide lattice is found, compds. of the formula MRO_4 being represented by $MO.RO_3$. At elevated temps. sufficient oscillation of the elements about their lattice positions occurs to produce variations in structure. Thus a compd. of compn. MRO_4 will probably have a pure ion lattice of the first type at room temp., but at elevated temps. there will be sufficient oscillation about the lattice positions to produce a transformation to the 4th type, equil. being finally produced as follows: $MRO_4 \rightleftharpoons M\,O.RO_3$. With increase in temp. this is displaced more and more to the right. The occurrence and identification of these various types of lattice structure are discussed fully. **II. Tungstates and molybdates of bivalent metals.** *Ibid* 295–316.—Cond. detns. are made to det. the type of lattice structure of certain tungstates and molybdates. $NiWO_4$, $MnWO_4$ and $ZnWO_4$ are purely electronic conductors; $CdWO_4$ and the alk. earth tungstates and molybdates conduct the current either as ions or as mixed oxides. $MgWO_4$ shows such a high sp. resistance that significant results are not obtained, although it appears to be an electronic conductor. From the cond. data as well as diffusion expts. and a few reactions in the solid state it is

concluded that $NiWO_4$, $MnWO_4$, $ZnWO_4$, $MgWO_4$ and the corresponding molybdates possess a double oxide lattice between 600° and 1100°, while $CdWO_4$ and the alk. earth tungstates and molybdates show an ion lattice over the same temp. range. In $CdWO_4$ indications are also given of an equil. in the crystal between the ions Cd and WO_4 and the individual oxides CdO and WO_3. H. STOERTZ

Determination of the type of linkage by means of the lattice energy. WILHELM KLEMM. *Z. Elektrochem.* **36**, 704–11(1930).—The lattice quotients of halides were studied. The lattice quotient of a compd. is defined as the ratio of its lattice energy to that of a halide of an element in a main group of the periodic table of similar size and charge as the element under consideration. With gaseous compds., the energy liberated in the formation of the mol. from gaseous ions is used in place of the lattice energy. The lattice quotient characterizes a compd. as definitely as its b. p., density, etc. It is not yet possible to state the place in the periodic table at which ionic bonding changes to at. linkage. I. J. PATTON

The space group of strychnine. THORA C. MARWICK. *Nature* **126**, 438(1930).—The x-ray investigation of strychnine revealed the following: unit cell $a = 11.9_2$A. U., $b = 12.1_3$A. U., $c = 11.3_6$A. U., vol. = 1634A. U.^{3}; axial ratios: $a:b:c = 0.983:1:0.931$; no. of mols. = 4; space group Q_4. The dimensions of the cell, and the space group, are such that 4 of the disk-shaped mols. recently suggested by R. Robinson (Bakerian lecture) can be fitted in the unit cell. LOUIS WALDBAUER

Crystal structure in the system: copper–bismuth. WM. F. EHRET AND RAY D. FINE. *Phil. Mag.* [7], **10**, 551–9(1930).—The photograms of a series of alloys ranging from pure Cu to pure Bi show the characteristic diffraction pattern of both metals. Within the limits of error, the lattices remain unchanged and indicate low mutual solubilities and the formation of heterogeneous alloys. The Cu lattice parameter was found to be 3.607 ± 0.004 A. U. and the Bi lattice parameter 4.749 ± 0.005 A. U. ARTHUR FLEISCHER

Investigations on carbides. I. The crystal structure of carbides MC_2. M. v. STACKELBERG. *Z. physik. Chem.*, Abt. B, **9**, 437–75(1930); cf. *C. A.* **24**, 3689.—X-ray investigation by the powder method of a series of carbides of formula MeC_2 shows that they have a face-centered tetragonal lattice with 4 mols. in the unit cell and lattice consts. as follows, recording *a*, *c* and the d. in order: CaC_2 5.48, 6.37, 2.21; SrC_2 5.81, 6.68, 3.26; BaC_2 6.22, 7.06, 3.90; LaC_2 5.54, 6.55, 5.35; CeC_2 5.48, 6.48, 5.56; PrC_2 5.44, 6.38, 5.75; NdC_2 5.41, 6.23, 6.08; ThC_2 5.85, 5.28, 9.3; $NaHC_2$ 5.40, 8.17, 1.33; KHC_2 6.05, 8.42, 1.37. The C–C distance in the C_2 group is 1.4 A. U., agreeing with band spectra data. With the help of the polarizing microscope the tetragonal symmetry was confirmed for CaC_2, SrC_2 and BaC_2. An electron configuration similar to that of the N_2 mol. is postulated for the C_2 and HC_2 groups. The possible space group classifications are discussed. These carbides appear to show a new lattice type somewhat similar to that of pyrite. J. B. AUSTIN

The dependence of crystal plasticity on temperature. W. BOAS AND E. SCHMID. *Z. Physik* **61**, 767–81(1930); cf. *C. A.* **24**, 3686.—By use of a Schopper tenacity app. so modified that the specimen may be immersed in an oil bath, thrust tension and the tenacity of 14 Cd crystals were measured. The crystals were prepd. by the method of Czochralski, namely, by drawing from a melt at 20 cm./hr.—at temps. 20–473°K. The crit. thrust-tension falls linearly with increase in temp. to 473°K; beyond this temp. it is const. for a considerable period below the m. p. The tenacity coeff., which is the slope of the tenacity curve, falls with temp. between 100° and 300°K. At higher and lower temps. it is practically independent of temp. At high and low temps. the rate of applying the load is without effect on the coeff. The work of thrust is independent of temp. and the rate of stretch; it is 8.7 joules/cc. Zn crystals stretched at 100°, 150° and 300° C. show a transverse striation which may indicate the superficial destruction of the crystal. Detailed data, curves and photographs are given. E. R. SCHIERZ

Field strength dependence of polarization and true conductivity in ion crystals. ADOLF SMEKAL with research by O. BERAN and F. QUITTNER. *Physik. Z.* **31**, 809–11(1930).—The satn. value of the polarization was detd. at high voltages for NaCl and KCl from 114° to 300° with an accuracy of 2 to 3%. The true cond. of crystals increases with rise of field strength at all the temps. at which measurements were made. The true cond. of ion crystals does not obey Ohm's law but rather obeys Poole's formula. ARTHUR FLEISCHER

Electrical conductivity measurements at low temperatures. J. C. MCLENNAN, J. F. ALLEN AND J. O. WILHELM. *Phil. Mag.* [7], **10**, 500–11(1930).—The cond. from 1.9° to 300°K. was measured for the eutectic alloys of Ag-Bi, Cu-Bi, Mn-Bi, Ag-Sb,

Cu-As, Au-As, solid solns. of Cd-Bi, Cd-Sb, the alloys Pb-Ce, Pb-La, and Ce, La, AgCl, FeS, AgS, Bi_2S_3, CuO, PbS, and an old sample of Po. PbS was found to be supra-conducting at 4.2° while Cu-As, Au-As and Cd-Bi showed signs of a possible supra-conducting state below 1.9°. ARTHUR FLEISCHER

Further experiments on the cohesion of quartz fibers. G. A. TOMLINSON. *Phil. Mag.* [7], **10**, 541–4(1930); cf. *C. A.* **23**, 559.—Contrary to the experiences of Stone (cf. *C. A.* **24**, 4197) with glass beads, quartz fibers adhered even in a dry atm. for a long time. Two other examples of solid cohesion are: (1) A light disk having 3 in. of clean Pb is placed on a plate of clean glass or steel; on careful inversion the disk clings to the plate. (2) If clean glass is stroked repeatedly with a metal, a thin film appears which gradually increases in thickness assuming the characteristic color of the metal, and showing great tenacity. ARTHUR FLEISCHER

The expansion of metals at high temperatures. FDK. L. UFFELMANN. *Phil. Mag.* [7], **10**, 633–59(1930).—The expansion coeffs. were detd. by an optical interference method for 3 directions up to 800°. Sn, Cd and Zn showed pronounced anisotropic properties. The results are expressed in 2 equations: (1) $V = V_0(1 + At + Bt)$, where V = vol. at temp. t and V_0 = vol. at 0°. (2) Thiessen's formula $\alpha = K/V \cdot T^n$, where α is the coeff. of expansion. For Sn, Cd and Zn the cubical expansions are used; for the others the linear expansion.

Metal	Range	Equation 1		Equation 2	
		$A \times 10^{+5}$	$B \times 10^{8}$	$K \times 10^{6}$	n
Sn		Neither 1 nor 2 fits data over whole range			
	120 90°	5.05	9.9	...	....
Cd	90–130	...	...	2 25	0.626
	130–270	8.04	5 9	4.27	0.519

Co, Ni and Fe showed coeffs. that vary according as the measurement is made with rising or falling temp. ARTHUR FLEISCHER

The spark potential in helium. FRITZ LEVI. *Ann. Physik* [5], **6**, 409–33(1930).—Curves of spark potential in pure He plotted against product of gas pressure and distance between electrodes were approx. detd. but are not as reproducible as for other gases. With increasing purity of He, the curve first falls and then rises sharply. Traces of foreign gases and the state of the electrode surface probably account for the discrepancies. Polarization was always present, brass electrodes giving higher results than those of Ni. G. M. MURPHY

Quick evaporation. HANS N. NAUMANN. *Biochem. Z.* **226**, 164-5(1930).—Reply to a criticism of Jantzen and Schmalfuss (*C. A.* **24**, 3933). S. MORGULIS

The heat of vaporization of water and the specific volume of saturated steam up to 310° (100.7 atm.). M. JAKOB AND W. FRITZ *Z. Ver. deut. Ing.* **74**, 1266 (1930); cf. *C. A.* **24**, 4441.—The former investigation was extended to 310°. The results are, resp., temp. in degrees, pressure in kg./sq. cm., heat of vaporization in kg. cal./kg. and sp. vol. of satd. steam in cu. m./kg.: *270, 56 10, 381.94, 0.03554; 285, 70.48, 361.38, 0.02777; 300, 87.61, 334.73, 0.02153; 310, 100.65, 315.68, 0.01829.* G. M. MURPHY

Investigation of the conductivity of water which has been irradiated with x-rays. R. SCHNURMANN. *Z. physik. Chem.*, Abt. A, **150**, 110–4(1930). —Pure H_2O which has been exposed to x-rays does not permanently acquire increased cond. if it was irradiated through a Pt window which also served as an electrode of the cond. cell. The temporary increase in cond. is attributed to heat radiation from the x-ray tube. L. W.

Vapor pressure and constitution of the vapor of mercurous bromide. GERHARD JUNG AND WERNER ZIEGLER. *Z. physik. Chem.*, Abt. A, **150**, 139–44(1930); cf. *C. A.* **24**, 5621.—By use of the Dumas method the vapor d. of Hg_2Br_2 at temps. between 403° and 443° was found to be 9.863; the value calcd. for complete dissocn. is 9.861. At a vapor pressure of 1.3 mm. the Hg resonance line (253.7 mμ) is visible in the absorption spectrum for Hg_2Br_2 vapor. At higher pressures the Hg spectrum is blotted out by that of $HgBr_2$. Conclusion: Hg_2Br_2 is completely dissocd. into $HgBr_2$ and Hg. The vapor pressure of Hg_2Br_2 (detd. by the dynamic method between 97° and 185° and by the

sublimation method between 320° and 395°) is given by the expression: $\log p = -(4298/T) + 9.338$ over the temp. range 100–400°. On the basis of one mol. of Hg_2Br_2 the heat of dissocn. into Hg and $HgBr_2$ is 39,200 cal. and the heat of vaporization of Hg_2Br_2 is 52,000 cal. OSCAR T. QUIMBY

The electrical conductivities of dilute sodium amalgams at various temperatures. W. J. DAVIES AND E. J. EVANS. *Phil. Mag.* [7], **10**, 569–99(1930); cf. *C. A.* **23**, 1027.—The conductivities of 11 Na amalgams from 0.307 to 5.270 atom % of Na were measured at 8 temps. from 0° to 300°, with special precautions to prevent oxidation and contamination. For a const. concn. up to 3.6% the relative resistance increases with temp. up to 185°. At const. temp. the resistance rises to a max. with increasing concn. and then falls; the rise is steeper than the fall. The resistance of the amalgams is greater than the resistance of Hg except at 5.27 atom % of Na, where there sepd. a solid mass which seemed to have a cryst. structure. ARTHUR FLEISCHER

Adsorption of methane and hydrogen on charcoal at high pressure. P. K. FROLICH AND A. WHITE. *Ind. Eng. Chem.* **22**, 1058–60(1930).—Adsorption isotherms of CH_4 and of H_2 on charcoal were detd. over the pressure range of 1 to 150 atms.; those for H_2 were taken at 25° and at 100°, those for CH_4, at 25°, 50°, 100° and 180°. The adsorption increases with pressure in accordance with Langmuir's rather than with Freundlich's equation, reaching a satn. value at about 100 atms. and 25° of 12 l. per 100 g. of charcoal for CH_4 and 4 l., for H_2. From mixts. of the 2 gases at 25°, CH_4 appears to be adsorbed preferentially practically to the complete exclusion of H_2 and in an amt. approx. equal to that adsorbed at the same partial pressure of CH_4 in the absence of H_2. P. H. E.

Experimental studies on adsorption by means of x-rays. MORISÔ HIRATA. *Sci. Papers Inst. Phys. Chem. Research* **14**, 71–90(1930); cf. *C. A.* **24**, 1779.—X-ray diffraction patterns of coconut charcoal contg. the vapor of some org. liquid in an adsorbed state were studied and compared with those of the activated charcoal and those of the pure liquid. In PrOH, iso-PrOH and AmOH, the diffraction figures of the charcoal contg. their vapors are different in nature from those that are obtained by the simple superposition of that of the pure liquid on that of the activated charcoal. The expts. are considered to indicate a definite combination of mols. somewhat different from that in the ordinary liquid state. With CS_2, the data can be explained as resulting from the superposition of the diffraction pattern of liquid CS_2 upon that of the charcoal. PAUL H. EMMETT

A theory of condensation and adsorption. N. SEMENOV. *Z. physik. Chem.*, Abt. B, **7**, 471–9; *J. Russ. Phys.-Chem. Soc.*, Phys. Pt., **62**, 33–9(1930).—Theoretical. The adsorbed monomolecular layer is analogous to a two-dimensional gas; hence van der Waals' equation may be applied to it. At high pressure, the layer becomes a two-dimensional liquid accompanied by a satd. vapor phase. ALBERT L. HENNE

Adsorption in solutions and the dielectric properties of the solvent. ERICH HEYMANN AND ERICH BOYE. *Kolloid-Z.* **53**, 83–5(1930); cf. *C. A.* **24**, 2656. A. F.

Adsorption phenomena in solutions. XXI. The surface oxides of active charcoal. NIKOLAI SHILOV, HELENE SHATUNOVSKA AND KONSTANTIN CHMUTOV. *Z. physik. Chem.*, Abt. A, **150**, 31–6(1930); cf. *C. A.* **24**, 4975.—Chem. as well as phys. and elec. characteristics of the surface det. the adsorptive properties of active charcoal. Oxide B adsorbs KCl hydrolytically according to the equation $=C\langle^{OH}_{OH} + 2KCl \longrightarrow =C\langle^{Cl}_{Cl} +$ $2KOH$. Oxide C adsorbs KCl without hydrolytic cleavage: $=C\langle^{OH}_{OH} + 2-C\langle^{O}_{OH} +$ $2KCl \longrightarrow =C\langle^{Cl}_{Cl} + 2-C\langle^{O}_{OK} + 2H_2O$. The importance of the chem. properties of the surface oxides is further demonstrated by the behavior of active charcoal and $AlCl_3$ Na_2HPO_4, Na_2CO_3 and KI. However, adsorption is not regarded as a purely chem. exchange reaction. DON BROUSE

Adsorption phenomena in solution. XXII. The orientation of the adsorption series in its dependence on the state of activation of sugar charcoal. MICHAEL M. DUBININ. *Z. physik. Chem.*, Abt. A, **150**, 145–60(1930); cf. *C. A.* **23**, 1549.—Sugar charcoal activated at 500° adsorbed mineral acids from aq. solns. of equiv. concn. in the order $HCl > H_2SO_4 > H_3PO_4$, and org. acids in the order propionic > valeric > heptylic. When the charcoal was activated at 800° or for long periods of time the order of adsorption was reversed. Activation in air decreased the adsorption of I from KI soln. and increased

that of alkali. Activation in CO_2 increased the adsorption of I but did not affect that of alkali. Heating the charcoal *in vacuo* to 1000° destroyed its ability to adsorb alkali by removing the surface layer of CO_2. By this treatment the ability to adsorb acids was also decreased, but the amt. of I adsorbed was practically unchanged. Activation increases the pore size, allowing the larger mols. access to more surface. The amt. of the larger mols. adsorbed per unit mass of adsorbent is thereby increased in greater proportion than that of smaller mols. C. W. WILSON

The effect of the surrounding medium on the life of floating drops. L. D. MAHAJAN. *Phil. Mag.* [7], **10**, 383-6(1930); cf. *C. A.* **23**, 4118.—Drops of H_2O, soap soln. and aniline were placed in air, CO_2, gasoline, H_2O and olive oil at various temps. As the viscosity of the surrounding medium increased, the life of the drop increased. A. F.

The variation of electrical resistance with applied potential. II. Thin collodion films. L. R. BLINKS. *J. Gen. Physiol.* **14**, 127-38(1930); cf. *C. A.* **24**, 5319.—The resistance of very thin collodion membranes to d. c. resembles that of living cells in that it varies with the p. d. With membranes sepg. 2 different solns., the resistance varies with the direction and voltage of the applied p. d. When less mobile ions are carried across the membrane the p. d. rises, when more mobile ions are so carried it falls, the changes being prompt and regular. There is a hysteretic effect of previous current flow. These membranes differ from *Valonia ventricosa* cells in that the rise of resistance is largely ohmic, with little or no polarization p. d. **III. Impaled Valonia ventricosa.** L. R. BLINKS. *J. Gen. Physiol.* **14**, 139-62(1930).—*Valonia* cells were impaled upon fine glass capillaries and the elec. resistance and polarization were measured during the passage of d. c. across a single layer of protoplasm. The measurements were correlated with 5 stages of p. d. existing naturally across the protoplasm: (1) stage of shock after impalement, in which the p. d. reaches zero and then slowly recovers, the resistance and polarization being slight; (2) stage of recovery characterized by normal p. d. (15 mv. av.), inside of cell pos., polarization and resistance at first variable but finally reaching a "constant" state; (3) stage of increased p. d. (to 100 mv.), inside of cell pos., polarization and resistance being at first as in sea water but later decreasing; (4) a temporary stage of reversed p. d. (to 50 mv.), outside of cell pos., with polarization greater to outward than to inward currents; (5) disappearance of p. d. caused by death and various toxic agents, the resistance and polarization being negligible. The apparent resistance of the protoplasm is largely accounted for by the apparent back e. m. f. of polarization. The elec. capacitance of the protoplasm is about 1 microfarad per sq. cm. of surface. C. H. RICHARDSON

Color and particle sizes of colloidal silver, especially of the new hydrogen peroxide-silver sol. E. WIEGEL. *Kolloid-Z.* **53**, 96-101(1930); cf. *C. A.* **23**, 3389; **24**, 3415.—The table gives the sizes of the Ag particles corresponding to the various colors:

Transmitted Color	Particle Size mμ	Method
Yellow	10–20	Particle count
Red	25–35	Particle count
Red-violet	35–45	Particle count
Blue-violet	50–60	Particle count
Blue	70–80	Sedimentation velocity
Green	120–130	Sedimentation velocity

The reflected color is always the color complementary to the transmitted color. The results agree with Mie's theory if anisotropic particles are assumed. The Ag crystals tend to have a leaf form. There is no doubt that the color depends on the particle size. ARTHUR FLEISCHER

Colloidal nature and water content of clays. H. BERRIDGE. *Engineering* **130**, 5-7, 61-3(1930).—The relation between the phys. properties of clay and the stability of building foundations was investigated. Even when loaded to more than 5 tons per sq. ft., dried clay expands when wetted, and the limiting pressure required to prevent expansion seems to be approx. 15 tons per sq. ft., as calcd. from the laws governing osmotic pressure. As plastic clay dries, shrinkage practically ceases when the water content falls below about 12.5% of the dry wt., but spontaneous evapn. of water continues until it reaches about 6%. Prisms of clay without lateral support failed completely at a pressure of 1 ton per sq. ft. when the water content of the clay was 22.8 gal. per cu. yard., while air-dried clay supported a pressure of at least 4 tons per sq. ft. K. D. JACOB

The behavior of highly polymerized compounds in solution. H. MARK. *Kolloid-Z.* **53**, 32-46(1930).—The viscosity relations, vapor pressure lowering, spreading on surfaces and x-ray investigations of colloid solns., especially cellulose and cellulose ester solns., are reviewed. ARTHUR FLEISCHER

Deformation of high-molecular compounds. R. O. HERZOG. *Kolloid-Z.* **53**, 46–51(1930).—The properties of macromols. lead to 2 results: (1) cohesion is greatest in the direction of the fiber axis; (2) in the deformation of a mixt., the large and small mols. react differently. Examples used to illustrate are polyvinyl acetate, polyacrylic acid esters and cellulose esters. ARTHUR FLEISCHER

Highly polymerized compounds. XLVI. Organic and colloid chemistry. H. STAUDINGER. *Kolloid-Z.* **53**, 19–32(1930); cf. *C. A.* **24**, 5294, 5717.—A review in which the micellar theory is compared with S's. theory of macromols. Org. colloids are classified as follows: (1) lyophobic suspensoids and emulsoids which have low viscosities and which contain few large, approx. spherical particles (rubber latex). (2) Assocn. or micellar colloids, usually heteropolar org. materials of which the anion or cation is a large org. radical, giving colloid solns. in water (soaps). (3) Mol. colloids or compds. with very large mols. (*macromols.*) which dissolve in suitable solvents to yield very viscous liquids. Depending on the thermal properties, this class is divided into hemicolloids and eucolloids (polystyrene, rubber, etc.). ARTHUR FLEISCHER

Spatial representation of the structure of carbon compounds and their use in the chemistry of highly polymerized compounds. KURT H. MEYER. *Kolloid-Z.* **53**, 8–19 (1930).—Models are constructed for cellulose, rubber and protein from chem. and phys. data, especially those from x-ray measurements and from calcns. of the "molcohesion" (cf. *C. A.* **23**, 1623). ARTHUR FLEISCHER

Zwitterions. I. Proof of the Zwitterion constitution of the amino-acid molecule. LESLIE J. HARRIS. *Biochem. J.* **24**, 1080–5(1930).—**II. Amino acids, polypeptides etc., and proteins as Zwitterions with instances of non-Zwitterion ampholytes.** THOMAS WM. BIRCH AND LESLIE J. HARRIS. *Ibid* 1086–97.—Evidence is brought forward to show that amino acids possess the Zwitterion structure ($^+NH_3.R.COO^-$) rather than the classical structure ($NH_2.R.COOH$). The older view is represented as $Cl^- +$ $^+NH_3.R.COOH \xleftarrow[(k_b;\ \text{low})]{+HCl} {}^+NH_3.R.COOH \xrightarrow[(k_a;\ \text{low})]{+NaOH} {}^+NH_2.R.COO^- + Na^+$..... The new view is represented as $Cl^- + {}^+NH_3.R.COOH \xleftarrow[(K_a;\ \text{high})]{HCl} {}^+NH_3.R.COO^- \xrightarrow[(K_b;\ \text{high})]{NaOH} NH_2.R.COO^- + Na^+$.... In the newer view the amino group of the free amino acid is already ionized, so that addn. of HCl merely serves to depress the ionization of the carboxyl group (the acid carboxyl group is "replaced" by the stronger acid, HCl). The NaOH, on the other hand, being a stronger base "replaces" the weaker amino group, and the ionization of the carboxyl group is left unchanged. The addn. of HCl, then, measures K_a and not K_b; and similarly with NaOH The HCl and NaOH titration curves of glycine were detd. in the presence of increasing concns. of HCHO. The weakening of the basicity of the NH_2 group caused by the formation of a methylene deriv. resulted in a displacement not of the HCl curve but of the NaOH curve. The HCl and NaOH titration curves represent, therefore, not neutralization of NH_2 and COOH, resp., but "replacement" (back titration) of COOH and of NH_2 by a stronger acid and a stronger base. With ampholytes contg. more than 1 NH_2 or COOH group the no. of curves shifted is shown to be equal to the no. of basic groups. The method has been used to det. whether a given ampholyte possesses the Zwitterion or non-Zwitterion constitution. Polypeptides are Zwitterions; *p*-aminophenol and *p*-aminobenzoic acid are non-Zwitterions. BENJAMIN HARROW

Constitution and electrochemical behavior of proteins. WOLFGANG PAULI. *Kolloid-Z.* **53**, 51–61(1930).—The prepn. of electrolyte-free proteins by electrodialysis has yielded accurate data on cond. and H-ion activity in protein solns., and has permitted accurate calcns. of Zwitterion concns. The behavior of proteins toward neutral salts, toward acid and alkali addns., toward flocculating agents in the presence of acids, at the isoelec. point and toward the Ag ion are discussed from the standpoint of the Zwitterion. ARTHUR FLEISCHER

The thermodynamics of lyophilic colloids. HANS KROEPELIN. *Kolloid-Z.* **53**, 86–8(1930).—Equations useful for the study of swelling substances are derived. ARTHUR FLEISCHER

Hydrates and hydrogels. XII. Mono- and disilicic acids. R. WILLSTÄTTER, H. KRAUT AND K. LOBINGER. *Ber.* **62B**, 2027–34(1929).—Monosilicic acid was obtained in a purer state by shortening the time of reaction and controlling the acidity at 0.002–0.001 *N*. Both mono- and di-acids are most stable in feebly acid solns. Neutral or slightly alk. solns. hasten condensation. The acidity affects the properties of silicic acids (mol. wt. 200–300) as shown by the reaction with albumin. Time-*vs.*-mol. wt.

curves illustrate the condensation of monosilicic acid in solns. of differing acidities. Poly. alcs. retard condensation; EtOH is ineffective. During distn. of a silicic acid soln., traces of the acids are volatilized, whereas a soln. of boric acid gives no trace of acid in the distillate. ALBERT L. HENNE

An attempt to explain gel phenomena on the basis of properties of fluids with viscosity anomalies. D. DEUTSCH. *Z. physik. Chem.*, Abt. A., **150**, 161–8(1930).—A gel is assumed to be a plastic fluid. From this standpoint the phenomenon of thixotropy is seen to depend on hydrostatic pressure. Brownian motion, and the very small but finite diffusion of colloidal particles such as particles of azo blue dye, can be understood as the result of the plasticity of the gel. C. W. WILSON

Molecular weight of cocosin. BERTIL SJÖGREN AND ROMUALD SPYCHALSKI. *J. Am. Chem. Soc.* **52**, 4400 4(1930).—Cocosin (coconut globulin) is rather unstable, being easily decompd. during prepn. Centrifugal analysis proved cocosin to be a mixt. of 2 main components of wt. about 208,000 and 104,000 with the larger mols. present in much greater amts. than the smaller ones. It is extremely probable that native cocosin has a mol. wt. within exptl. limits identical with the other oil-seed globulins earlier studied, *viz.*, 208,000. The small fraction with half this wt. represents the 1st stage of the protein cleavage. The light-absorption curve is given. C. J. WEST

The physical chemistry of starch and bread making. I. The changes in the Röntgen spectrum of starch during baking and staling of bread. J. R. KATZ. *Z. physik. Chem.*, Abt. A., **150**, 37 59(1930).—The Rontgen spectrum of wheat or rye starch is of a typically cryst type (an A-spectrum) with somewhat broadened interference rings; the spectrum of the gluten present is not intense enough to be seen. In baking, a new form of crystal spectrum (a "paste formation" or V-spectrum) appears, indicating a new chem. compd. or an allotropic modification. Staling without loss of water produces a third spectrum (a retrogradation or B-spectrum) which is somewhat similar to the A-spectrum. **II. The starch modification with the V-spectrum is the equilibrium form at higher temperatures while at lower temperatures it is the modification with the B-spectrum.** J. R. KATZ AND L. M. RIENTSMA. *Ibid* 60 66.—A heterogeneous equil. exists between the starch modification with the V-spectrum (α starch) and the modification with the B-spectrum (β_B starch). At higher temps., α starch is the equil. form; at lower temps. it is the β_B starch. The influence of moisture content on this equil. has not been detd. **III. First and second stages of paste formation.** J. R. KATZ AND L. M. RIENTSMA. *Ibid* 67–80.—Two stages of paste formation may be distinguished by changes in the Rontgen spectrum. The first stage results if wheat starch is heated with much water to 60–62.5° or with little water to 100°; it corresponds to the changes in baking. The second stage appears upon heating with much water to 90 100°. In the first stage the starch grain is swollen; in the second it has changed to a sac filled with a thin starch soln. The change from the first to the second stage of paste formation is different from the change from β to α starch. **IV. Paste formation in starch and mercerization of cellulose.** J. R. KATZ AND J. C. DERKSEN. *Ibid* 81–9. A V-spectrum results when wheat starch is made into paste with an aq. soln. of NaOH. The concn. of NaOH must be about 0.07 or 0.08 *N* before conversion of β_B into α starch begins; then, within a narrow range (0.07 to 0.104 *N*), the more concd. the soln. the more starch is converted. The action is analogous to mercerization of cellulose with aq. NaOH. **V. All varieties of starch have similar retrogradation spectra.** J. R. KATZ AND TH. B. VAN ITALLIE. *Ibid* 90–9.—While all native starches display characteristically different Röntgen spectra (A), in the second stage of paste formation all have similar retrogradation spectra (B). This common retrogradation spectrum resembles the A-spectra of certain native starches (as potato, canna, etc.). The paste formation spectra (V) for all types of starches are similar. **VI. Changes in the Röntgen spectra upon drying starch derivatives.** J. R. KATZ AND J. C. DERKSEN. *Ibid* 100–9.—The Röntgen spectra of all substances belonging to the starch group change when the material is strongly dried. With the raw starch, the A-, B- or C-spectrum changes to a poorly defined diagram similar to an amorphous spectrum. The amt. of drying necessary to cause the change varies with the starch. The paste formation spectrum also changes characteristically to produce a new cryst. spectrum (VT-spectrum). The water of crystn. is apparently bound in a manner similar to that in a zeolite. D. BROUSE

Solubility relations in gas-liquid systems. IV. The solubility of oxygen in water as found by an analytical method. J. LIVINGSTON, R. MORGAN AND ALAN H. RICHARDSON. *J. Phys. Chem.* **34**, 2356–66(1930); cf. *C. A.* **24**, 5203.—The soly. of O_2 in water at pressures between 175 mm. and 760 mm. obeys Henry's law. The soly. detd. analytically agrees well with that obtained by other methods. PAUL H. EMMETT

The crystallization of sodium bromide from supersaturated solutions. I. N.

STRANSKI AND Z. C. MUTAFTSCHIEW. *Z. physik. Chem.*, Abt. A, **150**, 135–8(1930).—Cubes of NaBr crystallize out on compds. like sphalerite, rutile, magnetite and others whose crystal lattices differ widely from that of NaBr, as well as on PbS, which has the same lattice. The soly. of NaBr at 39° is 53.6 ± 0.05 parts by wt. per 100 of soln.
LOUIS WALDBAUER

The diffusion of substances that show deviations from Fick's law. D. KRÜGER AND H. GRUNSKY. *Z. physik. Chem.*, Abt. A, **150**, 115–34(1930).—A discontinuous method of diffusion which permits of recognizing deviations from Fick's law more easily than Öholm's method is described. The new method permits the evaluation of the results in cases where the diffusion coeff. depends on concn. Expts. with the sols of cellulose esters lead to the conclusion that the abnormal diffusion depends, not only on a diffusion coeff. varying with concn., but also on attractive forces between dissolved cellulose ester particles, and between ester and solvent mols. LOUIS WALDBAUER

Diffusion. II. Kinetic theory of diffusion in liquid systems. J. HOWARD ARNOLD. *J. Am. Chem. Soc.* **52**, 3937–55(1930); cf. *C. A.* **24**, 5549.—The classical kinetic theory is applied to diffusion in liquids. Assumptions made are: (1) resistance to diffusion is due to binary collisions; (2) shortening of the mean free path due to vol. of mols. is the same for all systems. The retarding effect of intermol. forces is allowed for by an empirical factor which is used with assocd. substances. This factor is independent of the nature of the diffusing substance and is proportional to the viscosity of the solvent. Observed and calcd diffusion coeffs. are compared. S. LENHER

The molecular state and mutual reactions of the halides in the 4th and 5th group of the periodic system. M. G. RAEDER. *Kgl. Norske Videnskab. Selskabs Skrifter* **1929**, No. 3, 1–118.—Cryoscopic and ebullioscopic investigations of mutual solns. of the halides in the 4th and 5th group of the periodic system were carried out systematically to clear up anomalies in previous investigations. (Cf. Walden, *Z. anorg. allgem. Chem.* **29**, 371(1902); Garelli and Bassani, *Atti acad. Lincei* [5], **10**, 255–62; Tolloczko, *Bull. acad. sci. Cracovie* [7/1], 22 pp.; Beckmann, *C. A.* **1**, 138.) The results are treated with special reference to the new soly. theory (*C. A.* **10**, 2426). Occurrence of reciprocal reactions and possible existence of mixed halides were investigated by establishing equil. diagrams for a series of binary halide systems. The cryoscopic consts. were detd. in a Beckmann app. provided with an electromagnetically driven Pt stirrer which permitted working with the hygroscopic halides in a completely closed app. Series of 3–5 measurements were made with increasing amts. of each dissolved compd. in the same solvent. The initial amt dissolved was regulated so as to give a depression in the f. p. of 0.2–0.5°. The av. mol. depression was calcd. for each series according to Raoult. The consts. obtained were plotted against g.-mols of substance per 100 g. solvent in a coördinate system, and the values for Δ at infinite diln. found by extrapolation. These values were controlled according to van't Hoff's empiric equation for dil. solns. Where the necessary thermochem. consts were not available the heats of vaporization of the resp. solvents were detd. ebullioscopically. For $SnBr_4$, m. 29–29.5°, the following values for Δ were obtained with the various halides, resp.: SnI_4 348, $SnCl_4$ 437, AsI_3 534, $AsCl_3$ 610, $AsBr_3$ 277, SbI_3 518, $SbBr_3$ 276, $SbCl_3$ 585, PI_3 446 immediately after addn. and 454 1–1½ hrs. after addn., PBr_3 264, PCl_3 283, CBr_4 275, CCl_4 270, $SiBr_4$ 136, $SiCl_4$ 260, $TiBr_4$ a slight tendency to raise the f. p., $TiCl_4$ 396. A series of the values for Δ is grouped around 275 and the 3 most reliable series give on an av. 276. Calcd. from this the heat of fusion, w = 6.59 cal./g. For $AsBr_3$, m. 32°, the values obtained for Δ were: AsI_3 186, $AsCl_3$ 227, SbI_3 55, $SbBr_3$ —122, $SbCl_3$ 95, PI_3 307, PBr_3 129, PCl_3 305, SnI_4 403, $SnBr_4$ 171, $SnCl_4$ 452, $TiBr_4$ 144, $TiCl_4$ 355, $SiBr_4$ 110, $SiCl_4$ 153, CBr_4 165, CCl_4 160, anthracene 182. The various halides are more sensitive to $AsBr_3$ than to $SnBr_4$. The value for the presumably indifferent anthracene is in fair agreement with that of Walden. It therefore seems probable that for $AsBr_3$ Δ = 185. Calcd. from this w = 9.93 cal./g. The ebullioscopic consts. were detd. in a Beckmann app., which, during varying atm. pressure, was provided with a Beckmann and Weber manostat (*C. A.* **6**, 1865). For $SnCl_4$, b. 114°, the following values for Δ were obtained: SnI_4 302, $SnBr_4$ 179, $TiBr_4$ 232, $TiCl_4$ 38, $SiBr_4$ 45, CBr_4 89.7, $SiCl_4$ and CCl_4 too volatile, SbI_3 309, $SbBr_3$ 207, $SbCl_3$ 73.5, AsI_3 243, $AsBr_3$ 153, $AsCl_3$ 15, PI_3 81 (stable), 112 (max.), PBr_3 0 and —7 (stable), 60 and 73 (max.), PCl_3 —146, anthracene 101. The ebullioscopic const. for $SnCl_4$ should thus be Δ = 98. For $TiCl_4$, b. 136°, the values obtained were: SnI_4 about 130, $SnBr_4$ 91, $SnCl_4$ —61, TiI_4 277, $TiBr_4$ 127, $SiBr_4$ 23.4, CBr_4 52.5, $SiCl_4$ and CCl_4 too volatile, SbI_3 about 160, $SbBr_3$ 142, $SbCl_3$ 44, AsI_3 104, $AsBr_3$ 67, $AsCl_3$ —30, PI_3 36 (stable), about 67 (max.), PBr_3 —72, PCl_3 very variable, anthracene 66. The latent heat of vaporization for $TiCl_4$ was detd. according to Clausius-Clapeyron as l = 48.8 cal./g., giving Δ = 67.8, which is in agreement with the value for anthracene solns.

The const. for $TiCl_4$ should thus be $\Delta = 67$. For $SiCl_4$, b. 57°, the values were: SnI_4 54, $TiBr_4$ 57, SiI_4 53.5, $SiBr_4$ 58, CBr_4 50.0, SbI_3 practically insol., $SbBr_3$ about 60, AsI_3 very little sol., max. increase in b. p. 0.047°, PI_3 56. All the compds. give nearly ideal solns. in $SiCl_4$. The av. $\Delta = 55$, corresponding to $l_{56.7}° = 39.3$ cal./g. The heat of vaporization was detd. as $l_{55.8}° = 40.4$ cal./g. The const. for $SiCl_4$ should thus be $\Delta = 54$. For CCl_4, b_{740} 76.1°, the values were: SnI_4 57, CBr_4 54, $SbBr_3$ 51, PI_3 51, AsI_3 not sufficiently sol. The heat of vaporization of CCl_4 is 46.4 cal./g. (Landolt-Börnstein), giving $\Delta = 52.5$. The halides investigated are indifferent to CCl_4 and give on an av. $\Delta = 53$. All data being considered, the const. for CCl_4 should be $\Delta = 52$. For $AsCl_3$, b. 130°, the values were: SnI_4 161, $SnBr_4$ 70, $SnCl_4$ —77, TiI_4 153.5, $TiBr_4$ 133, $TiCl_4$ white ppt. on the first addn. which dissolved on further addns. The ppt. was sol. in alc.; variable values, seem near —70, SiI_4 about 67, $SiBr_4$ 14.5, CBr_4 b. p. variable, $SiCl_4$ and CCl_4 were too volatile to give reliable results, SbI_3 229, $SbBr_3$ 168, $SbCl_3$ 62, AsI_3 166, $AsBr_3$ 110, PI_3, PBr_3 and PCl_3 did not give stable values, anthracene 70.5. $AsCl_3$ is active. An exptl. ebullioscopic const. for $AsCl_3$, $\Delta = 71.5$ and a calcd. const., $\Delta = 64.0$ are given. For PCl_3, b_{759} 75.6,° the values were: SnI_4 70, $SnBr_4$ 100, $SnCl_4$ 34, $TiBr_4$ about 130, $TiCl_4$ 41, $SiBr_4$ 45, SbI_3 about 150, $SbBr_3$ about 126, $SbCl_3$ 40, AsI_3 about 150, $AsBr_3$ 121, $AsCl_3$ 37, PI_3 108, PBr_3 about 90, anthracene 50. By considering the preceding osmotic consts. as the normal values, the anomalies within each series, *i. e.*, the deviations from Raoult's law, are explained as follows: Too small osmotic effect may be caused by a combined crystn., or vaporization, differences in the internal pressure, mol. assocns., or, in general, polarity of the components. Such influences could not be very noticeable in the present expts. because these halides have little polarity and possess uniform, low internal pressures. The trihalides of Sb and some of those of As are exceptions in this respect. The weak polarity also makes the tendency to form addn. compds. very slight. Well-crystd. double compds. were observed only in the Ti–P systems, where the compds. $TiCl_4.PCl_3$, $TiBr_4.2PBr_3$ and probably $TiBr_4.PBr_3$ were isolated. This anomaly is probably a result of the unsatd. character of the trihalides of P. Too high osmotic effect, which is far more pronounced, may be caused by electrolytic dissocns. or by chem. substitutions. The former can be eliminated because the compds. are non-ionizing and of too low polarity. Chem. substitutions appear more frequently either in the form of reciprocal conversions or of mixed halides. In most cases both types of reactions appear simultaneously. The reciprocal conversions can be sepd. into 2 groups. C and Si tetrahalides convert extraordinarily slowly with the halides of the other elements investigated and only at elevated temps., while the tetrahalides of Ti and Sn and the trihalides of P, As and Sb convert mutually very rapidly at ordinary temp. Contrary to the data of Karantassis (*C. A.* **20**, 1938, 2936) such reactions are reversible and in most cases without distinct direction. This condition is connected with the heat tones of the conversions, the latter always showing small values where an equil. is readily reached. The heat tones of possible reciprocal conversions with C and Si tetrahalides, calcd. from their heats of formation, are essentially higher and the conversions should therefore proceed more one-sidedly. The too high osmotic effects in such systems as SnI_4 in $SnBr_4$, AsI_3 in $AsCl_3$, etc., can be explained only by assuming a formation of mixed halides of the type $SnBr_2I_2$, $AsCl_2I$, etc. The disappearance of the characteristic colors of the iodides in the presence of excessive amts. of chlorides also speaks for the occurrence of such substitutions. Judged from the osmotic effects, this property of substitutions in the halides of the same element is strongest in Cl–I systems and weakest in Br–I systems. The osmotic anomalies are partly so great that they can be explained by a practically complete substitution. It is assumed that the substitutions take place in steps, *e. g.*, $3SnCl_4 + SnI_4 \rightleftarrows 4SnCl_3I$, $SnCl_4 + SnI_4 \rightleftarrows 2SnCl_2I_2$, $SnCl_4 + 3SnI_4 \rightleftarrows 4SnClI_3$. All steps are probably present simultaneously in solns. where the substitution is incomplete. In a previous paper (*C. A.* **18**, 636; **21**, 3324) it was shown that equil. diagrams of binary mixts. of Sn tetrahalides reveal no stable compds. The binary systems of As, Ti and Si halides here investigated showed no direct formation of intermediate compds. Since further the tetrahalide systems of Sn and Ti perfectly explain the f. ps. of the alleged mixed halides as given in the literature, without the assumption of compds., the mixed halides of these elements thus exist in soln. only and are not to be conceived as isolated, stable chem. individuals (Besson, *Compt. rend.* **124**, 683(1897); Lenormand, *J. pharm. chim.* **8**, 249 (1898); **10**, 114(1899); Friedel and Guérin, *Compt. rend.* **81**, 889(1875)). On freezing out or vaporization the equilibria are disturbed by the sepn. of more symmetrical and stable mols. of the single halides. While the binary systems of Si tetrahalides show no intermediate compds, they do not explain the f. ps. of the mixed halides as described by Besson (*Compt. rend.* **112**, 788, 1314, 1447(1891)), Besson and Fournier (*C. A.* **5**, 1885)

and Reynolds (*J. Chem. Soc.* **51**, 590(1887)). The existence of stable mixed compds., *e. g.*, $SiCl_2I_2.SiClBr_2$, etc., must therefore be assumed. From these results the following conclusion is drawn: The group P, As, Sb, Ti (probably Ge) and Sn form halides with readily interchangeable halogen atoms which, by a mere mixing together, enter into reciprocal conversions. The equilibria are easily displaced. Mixed halides are formed that cannot be isolated in solid or gaseous form. On the contrary the tetrahalides of C and Si have very little reactivity, are reluctant to enter into reciprocal conversions and form mixed halides only by special methods of prepn. When formed, these mixed halides can be isolated as stable compds. Cf. *C. A.* **1**, 2857; **3**, 603, 2077; **4**, 1276; **6**, 2720; **7**, 928; **9**, 402; **11**, 1588, 3146; **12**, 1436; **13**, 1663; **19**, 925, 3226; **20**, 2275; **22**, 1070. D. THUESEN

High-frequency conductivity of strong electrolytes in aqueous sugar solutions. S. MIZUSHIMA AND H. SACK. *Physik. Z.* **31**, 811–15(1930).—The cond. at 4×10^8 Hertz frequency for 0.005 to 0.4 molar solns. of $MgSO_4$ in 0 to 40% sugar solns. were measured by a comparative method with KCl as the standard. The results can be interpreted by the Debye electrolyte theory though not strictly quantitatively. A. F.

The electroösmotic salting out of concentrated solutions. R. HOFFMANN. *Wiss. Veröffentlich. Siemens Konzern.* **9**, 339–51(1930). F. D. ROSSINI

The interaction of molecules with the silver ion. FREDERICK K. V. KOCH. *Phil. Mag.* [7], **10**, 559–64(1930); cf. *C. A.* **22**, 1893.—The free energies of solvation for Ag ion in 10 org. liquids were calcd. from the previous exptl. data and compared with the free energies calcd. by the theory of Born on the assumption that the ion is a rigid sphere located in a continuous medium of dielec. strength. The difference is the extra energy expended in the excess mutual deformation above that due to induced moment. The errors are not sufficiently large to account for the observed regularities. Three classes occur, showing a gradual transition from solvation to complex-ion formation, (1) alcs., (2) nitriles and (3) N bases. Solvation may be defined as that state of ionic-mol. interaction in which the electronic configurations of the ions and mols. are quasi-rigid. ARTHUR FLEISCHER

Free energy of stannous hydroxyl chloride and the activity coefficient of stannous chloride and stannous ion. MERLE RANDALL AND SENZO MURAKAMI. *J. Am. Chem. Soc.* **52**, 3967–71(1930); cf. *C. A.* **22**, 3082.—The hydrolysis of stannous hydroxyl chloride was detd. in dil. HCl solns. at 25°, according to the equation, $Sn^{++} + Cl^- + 2H_2O(l) \rightleftharpoons SnOHCl.H_2O(s) + H^+$. Log $Km = m[H^+]/m[Sn^{++}]m[Cl^-]$ was plotted against the square root of the ionic strength. The 21 expts. gave points falling satisfactorily on a smooth curve. The activity coeffs. of $SnCl_2$ and of Sn^{++} were calcd. for vari. us concns. between $M = 0.0001$ and $M = 0.1000$. A. LLOYD TAYLOR

Activity coefficients of cesium chloride and hydroxide in aqueous solution. HERBERT S. HARNED AND ORION E. SCHUPP, JR. *J. Am. Chem. Soc.* **52**, 3886–92(1930); cf. *C. A.* **23**, 752, 1801.—From e. m. f. measurements of the cell Ag | AgCl | $Cs_xCl(m)$-Cs_xHg | $CsCl(m_0)$ | AgCl | Ag for concns. of CsCl from $M = 0.05$ to $M = 3.0$ the activity coeffs. of CsCl were calcd. by Hückel's equation (*C. A.* **19**, 1649) and by Harned's equation. Plotted values consistently fall below those for KCl as anticipated in the series of chlorides, HCl, LiCl, NaCl, KCl, CsCl. From e. m. f. measurements of the cell H_2 | $Cs(OH)(m)$ | CsHg | $CsOH(m_0)$ | H_2 for concns. of CsOH from $M = 0.01016$ to $M = 1.3205$ the activity coeffs. of CsOH were calcd. at all concns. They are somewhat above those for KOH. Details for the prepn. of very pure CsCl and CsOH are given. A. LLOYD TAYLOR

Activity coefficient and dissociation of water in cesium chloride solutions. HERBERT S. HARNED AND ORION E. SCHUPP, JR. *J. Am. Chem. Soc.* **52**, 3892–3900(1930); cf. preceding abstr.—The e. m. f. of the cell Ag | AgCl | HCl(0.01), $CsCl(m)$ | H_2 | HCl (0.01) | AgCl | Ag was measured for concns. of CsCl in the range $M = 0.01$ to $M = 3.0$ with satisfactory reproducibility below $M = 0.7$. By use of the equation, $E = 0.1183 \log (\gamma_{HCl}/0.904)[(m + 0.01)/0.01]$ the activity of the HCl was calcd. m_w for CsCl solns. passes through the expected max. and is lower than corresponding values in KCl solns. In the cell, H_2 | $CsOH(m_0)$, $CsCl(m)$ | Cs_xHg | $CsOH(m_0)$ | H_2, the e. m. f. was measured for concns. of CsCl between $M = 0.00503$ and $M = 3.6896$. The ionic activity coeff. product for water was calcd. by purely thermodynamic methods except for the math. extrapolation to zero concn. of acid or base and is given for concns. up to $CsCl(M = 1.0)$. Measurements were also made of the e. m. f. of the cell H_2 | $CsOHm_0$, $CsClm$ | AgCl | Ag, but exptl. difficulties make the results less certain. They are of value as a check. A. LLOYD TAYLOR

The determination of hydrogen-ion concentration in the presence of neutral salts. L. WOLF AND MISS D. ROSENTHAL. *Z. Elektrochem.* **36**, 803–6(1930).—Electrometric

and indicator methods do not give identical results for H-ion concns. in solns. contg. neutral salts. In order to det. whether the soln. is affected by the H electrode, the p_H of buffered phosphate solns. contg. KCl was detd. colorimetrically before and after an e. m. f. measurement. A difference ranging from −0.08 to −0.14 was found, which is named the *hydrogen effect*. The *salt error* therefore consists of the H effect plus a *true salt error* which is the same for similar indicators, but varies with the cations of the soln. The H effect was traced to some action of the Pt-H_2 couple on the soln. Neither the electrometric nor the indicator method gives the true p_H of such solns. J. H. R.

The theory of alkaline copper solutions and of the biuret reaction. WILHELM TRAUBE AND GERDA GLAUBITT. *Ber.* **63B**, 2094–8(1930).—A mechanism is suggested to explain the fact that $Cu(OH)_2$ dissolves in a soln. contg. both an alkali and a polyhydroxy or a biuret-type compd. but it does not dissolve in a soln. of either separately. Biuret and dulcitol both form alkali salts of little stability and may be brought into soln. by means of an excess of alkali. When $Cu(OH)_2$ is also added, these compds. dissolve much more easily and form stable alkali-cupri-salts which can be isolated. Since the org. compds. showing such behavior are all capable of acting as weak acids, it is suggested that they dissolve in alkali as anions by dissocg. one or more hydrogens, and that the $Cu(OH)_2$ is able to combine with these anions (but not with the undissocd. substance) to form a complex of greater acid strength so that the degree of ionization is increased and the org. substance is brought entirely into soln. Guanylurea and biguanide are able to bind $Cu(OH)_2$ in the absence of added alkali because they contain both acidic imino and basic amino groups. There is thus a tendency toward inner salt formation and a consequent inner ionization or amphoteric ion formation, while as before, $Cu(OH)_2$ combines with the ion to strengthen the acid properties of the dissocd. H. Similarly glyceryltrimethylammonium hydroxide is able to bind $Cu(OH)_2$ without the addn. of alkali. New compds. whose isolation and analysis are reported are diphenyliodonium cupribiuret and the corresponding Ni biuret, Th cupri-biuret and Th Ni biuret. R. C. H.

Gaseous oxidations. I. Homogeneous uncatalyzed reaction between oxygen and acetylene. GEO. B. KISTIAKOWSKY AND SAM LENHER. *J. Am. Chem. Soc.* **52**, 3785–96(1930).—Expts. are described showing that thermal oxidation of C_2H_2 by O_2 can be studied in Pyrex vessels between 250° and 315°. Comparison of reaction rates in packed and unpacked vessels shows that the reaction is homogeneous and of the chain type. The oxidation proceeds through the stages $C_2H_2O_2$ (glyoxal), HCHO and HCOOH. The gaseous products are mainly CO, with CO_2 and H_2. CO comes mainly from decompn. of $C_2H_2O_2$, and CO_2 from oxidation or decompn. of HCOOH. The origin of H_2 is uncertain. The rate of reaction is proportional to $[C_2H_2]^x$ and is independent of O_2 concn. In packed vessels the homogeneous oxidation is almost entirely suppressed, and the rate of reaction is proportional to $[C_2H_2][O_2]$. The mechanism of the reaction is discussed. S. LENHER

The heat of activation of bimolecular gas reactions and the hydrogen-chlorine reaction. J. FRANCK AND E. RABINOWITSCH. *Z. Elektrochem.* **36**, 794–9(1930).—For most reactions of the type $A + BC = AB + C$ the heat of activation bears a relation to the collision radii and nuclear distances of the factors and products. This is confirmed in a discussion of the reactions $Cl + H_2 = HCl + H$, $H + Cl_2 = HCl + Cl$, $F + H_2 = FH + H$. Some expts. on the action of ICl on H-Cl mixts. are described. Suggestions are made concerning the action of water, and visible and ultra-violet light on the photochem. H-Cl reaction. J. B. AUSTIN

The role of the liquid stationary film in batch absorptions of gases. I. Absorptions involving no irreversible chemical reactions. HAROLD S. DAVIS AND GEO. S. CRANDALL. *J. Am. Chem. Soc.* **52**, 3757–68(1930).—The reality of the liquid stationary film, the thin unstirred layer, on the surface of liquids is emphasized. For water stirred underneath at 1000 revolutions per min., the thickness is about 0.0045 cm. The rates of soln. of O_2 and of CO_2 by water and of O_2 by tetrachloroethane were measured. The time necessary to establish a uniform O_2 gradient through the stationary film depends on the degree of agitation of the water. The absorption rate of liquids stirred without breaking the surface increases with the stirring but tends to a max. With shaking the absorption rates were simply proportional to the solubilities of the gases. **II. Absorptions involving irreversible chemical reactions.** *Ibid* 3769–85.—The liquid stationary film theory is extended to cases where rapid chem. reactions take place in the soln. A study was made of the rates of absorption of CO_2 by water and by solns. of NaOH and KOH and of the rates of absorption of several olefin gases by H_2SO_4, both at rest and stirred beneath its surface. The effects of the reaction products on the liquid film diffusion coeff. were studied. Temp. changes in the film are discussed. P. T. N.

The binary system: iron-boron and the structure of the iron boride, Fe_2B. FRANZ

WEVER AND ANTON MÜLLER. *Z. anorg. allgem. Chem.* **192**, 317–36(1930).—The equil. diagram for Fe-B is detd. on the basis of thermal, microscopic and röntgenographic studies. It belongs to the group of Fe binary systems with very limited range of γ-phase, which because of limited soly. does not lead to the formation of a closed γ-field. The α-Fe-B mixed crystals are formed on the pattern of ordinary at. substitution. A complete structural analysis is made of the boride Fe_4B_2. It belongs to the tetragonal scalenohedric space group V_D^{11}, with 2 mols. of Fe_4B_2 in the base. The Fe atoms take an 8 point arrangement with 2 degrees of freedom. The parameters are $m = 1/6$ and $p = 2/10$. The B atoms have a 2 point arrangement with no degrees of freedom. H. S.

Crystal structure, electric conductivity, thermal forces and tempering phenomena of the system silver-platinum in relation to the phase diagram. C. H. JOHANSSON AND J. O. LINDE. *Ann. Physik* **6**, 458–86(1930).—The various measurements confirm in general the diagram of Doerinckel (cf. *C. A.* **1**, 2873). The boundaries of the miscibility gap in the solid were carefully detd. Under about 750° there are indications of 3, possibly 4, homogeneous regions. J. B. AUSTIN

The sorption of hydrogen sulfide by potassium benzenesulfonate and a thiohydrate of this salt. WILLY LANGE AND GERHARD LEWIN. *Ber.* **63B**, 2156–63(1930). — Compds. of the compn. $(PhSO_3K)_4.H_2O$ (I), $(PhSO_3K)_2.H_2O$ (II) and $(PhSO_3K)_4.H_2S$ (III) were prepd. from $PhSO_3K$ (IV). When H_2O vapor comes into contact with IV at 15° the H_2O content rises gradually with the pressure p (at equil.) to 5 mm. Hg at a concn. c of 1/4 (*i. e.*, the solid contains 1/4 H_2O per mol. of IV); p rises abruptly to nearly 10 mm. where it remains const. until $c = 1/2$; above 11 mm. the mass liquefies. The transition from II to I is marked by a mol. vol. change, but that from I to IV is not. For II $d_4^{18} = 1.604$ and for IV $d_4^{18} = 1.576$. If H_2S is confined with IV at 0°, the c of H_2S in the solid phase rises with p gradually at first, then more rapidly, finally approaching $c = 1/4$ asymptotically. The isobar at $p = 760$ mm. also approaches $c = 1/4$ at temps. 10–20° above the b. p. of H_2S. OSCAR T. QUIMBY

New examples of homogeneous catalysis. K. CLUSIUS AND C. N. HINSHELWOOD. *Z. Elektrochem.* **36**, 748–50(1930); cf. *C. A.* **24**, 2663. S. LENHER

Contribution to the problem of absorption catalysis. M. BORN AND J. FRANCK. *Nachr. Ges. Wiss. Gottingen Math.-physik. Classe* **1930**, No. 1, 77–89.—A theoretical treatment, mainly in terms of the synthesis of hydrazine. J. H. REEDY

Complex catalysts. A. MITTASCH. *Z. Elektrochem.* **36**, 569–80(1930).—A historical review of the development of complex or mixed catalysts. The oxidation of NH_3 and the reaction of CO with H_2 to give MeOH are discussed. Many references are included. A. LLOYD TAYLOR

The mechanism of the catalytic oxidation of ammonia. A. v. NAGEL. *Z. Elektrochem.* **36**, 754–7(1930). Low-temp. oxidation of NH_3 on mixed (Mn-contg.) catalysts was studied. At high rates of flow the products are NO and N_2; at lower rates of flow NO falls off and N_2O appears and increases in amt. as the flow decreases. At 350° and a flow of 0.5 l./hr. 70% of the NH_3 goes to N_2O. The results are explained by assuming the intermediate HNO (cf. Bodenstein, *C. A.* **21**, 1871) in the reactions, $2HNO = N_2O + H_2O$ at low temp. and $HNO + O_2 \longrightarrow NO \longrightarrow HNO_3$. S. LENHER

The decomposition of nitrous oxide on glowing platinum. H. CASSEL AND E. GLÜCKAUF. *Z. physik. Chem.*, Abt. B, **9**, 427–36(1930).—Measurements are given of the decompn. of N_2O at pressures of 0.1 mm. in the temp. range 1000–1800° abs. with and without addn. of O and N. The log of the dissocn. const. is a linear function of $1/T$. The following heats are calcd.: $1/2O_2 = O_{ads} + 21{,}700$ cal. $N_2O_{ads} = N_2 + O_{ads} + 38{,}000$ cal. J. B. AUSTIN

Dissociation of gypsum in presence of catalysts. I. E. ADADUROV, D. E. DERIBAS AND P. YA. KRAINII. *Zhur. Prikladnoĭ Khim.* **3**, 509–31(1930).—According to the resonance theory catalysts with wave lengths 4114–2576 A. U. induce dissocn. of $CaSO_4$ into CaO and SO_3, while catalysts with wave lengths 2576–1546 A. U. cause dissocn. into SO_2, SO_3 and O_2 and those with wave length less than 1545 A. U. dissoc. into SO_2 and O_2, particularly at high temp. Expts. confirm this theory. Salts of Cs, Ag, Na and Hg excite Ca atom (Ag_2O and Na_2SO_4 were tried); salts of Ce, Mg and Li excite ($MgSO_4$ and CeO_2 were tried) and salts of Os, Zn, W and Au excite O (Zn and W salts were tried). Catalyts that excite both Ca and O atoms (Al, Cu, Ni, Mo and Bi salts) or Ca, S and O atoms (Fe, V, Cr, Co, Ba and Mn salts) were also studied. Expts. showed that by choosing proper catalysts at 600° the yield of SO_3 can be raised from 0.18 to 25.85% while the yield of SO_2 is kept as low as 0.54% (MnO_2 used as catalyst). Conclusions: When the wave lengths of an element and of the catalyzed substance are the same it is a sure indication that this element is a catalyst. The catalytic activity diminishes with

increase in the wave length. Each wave length has a definite min. temp. at which it begins to show its activity. Each wave must carry a sufficient amt. of energy to break up the mol. It is therefore possible to calc. not only the direction of a reaction and its character but also its approx. temp. conditions and the catalysts to be used. V. K.

Dissociation of carbon monoxide on cobalt. H. A. BAHR AND V. JESSEN. *Ber.* **63B,** 2226–37(1930).—Finely divided metallic Co does not dissoc. CO at 225°. The dissocn. of CO takes place on the Co combined with 9.24% C as Co_2C. At temps. above 225° Co_2C decomposes, giving free C. No evidence of other Co carbides than Co_2C is found. Co carbide prepd. from CO dissocn. on finely divided Co gives up its carbide C as CH_4 on treatment with H_2 at temps. as low as 240–250°, while the carbide prepd. from free C + finely divided Co forms CH_4 on reacting with H_2 above 400°. S. LENHER

Catalytic properties of rhenium. HANS TROPSCH AND ROBERT KASSLER. *Ber.* **63B,** 2149–51(1930).—Reduced Re and Re-Cu catalysts act as hydrogenating catalysts in the reactions $CO \longrightarrow CH_4$ and $C_2H_4 \longrightarrow C_2H_6$. At 470° Re carbide is formed by passing CO over a Re-Cu catalyst. S. LENHER

Nickel molybdenum catalysts for the synthesis of ammonia. E. KEUNECKE. *Z. Elektrochem.* **36,** 690–2(1930).—The activity toward NH_3 synthesis of Ni-Mo catalysts of varying compn. was detd. at 200 atm., 550° and a gas flow of 50 l. per hr. per g. of metal catalyst. Freshly reduced catalysts possess an activity increasing linearly from 0 to 10.5% NH_3 as the Mo content increases from 0 to 70%, the activity of catalysts with more than 70% Mo decreases with increasing Mo content, becoming 1.5% on pure Mo. Three weeks' operation reduces the activity of catalysts contg. from 0 to 62% Mo to zero, but increases the activity of those contg. 80–100% Mo. The nitride content of the catalysts after a few hrs.' use is proportional to the Mo content, being 8% for 100% Mo catalysts; after 3 weeks' use the catalysts contg. less than 62% Mo lose practically all of their N; those above 62% in Mo content retain increasing amts. of N, as the Mo content approaches 100%. From magnetic, x-ray and metallographic data the results indicate that in the mixts. studied Mo is the catalyst, the Ni-Mo formed being a promoter. Neither the compd NiMo corresponding to 62% Mo nor the mixed crystals contg. 0–62% Mo are active catalytically. P. H. EMMETT

The thermodynamic treatment of stationary states in non-isothermal systems. II. Corrections and additions. CARL WAGNER. *Ann. Physik* **6,** 370–90(1930); cf. *C. A.* **24,** 1276. J. B. AUSTIN

Specific heats and latent heat of fusion of ice. W. H. BARNES AND O. MAASS. *Can. J. Research* **3,** 205–13(1930).—With an improved adiabatic calorimeter, the heat capacities of ice and resulting water from initial temps. between 0° and −78.5° to a final temp. of +25.00° were measured to ±0.05% or better. The sp. heats of ice over the temp. range 0° to −80° were found and the latent heat of fusion of ice at 0° was calcd. from heat capacity detns. The heat capacity of ice per g. at 0° was found to be 104.45 cals. and by taking the av. heat capacity of H_2O between 0° and +25.00° as 1.0020 the heat capacity per g. of H_2O over this range is 25.05 cals. The latent heat of fusion of ice at 0° is therefore 104.45 − 25.05 = 79.40 cals. per g. J. W. SHIPLEY

Heat of dissociation of fluorine. H. v. WARTENBERG AND J. TAYLOR. *Nachr. Ges. Wiss. Göttingen Math.-physik. Classe* **1930,** No. 1, 119–23.—Franck (*Z. physik. Chem.* **120,** 144(1926)) has shown that with Cl_2, Br_2 and I_2 the difference (Δ) in A. U. between the max. in the absorption spectrum and the point of convergence into a continuous spectrum is a linear function of the at. wt. By extrapolating the values for Cl_2, Br_2 and I_2, Δ for F_2 is calcd. as 1570 A. U. The max. in the absorption spectrum of F_2 is 2850 ± 50 A. U. The convergence was computed from this to be 4420 ± 50 A. U., from which the heat of dissocn. of F_2 is calcd. as 63.5 ± 0.7 Cal. Mixts. of carefully dried H_2 and F_2 are non-reactive, even under the influence of ultra-violet light. A mechanism dissimilar to the chain reaction proposed for the reaction between H_2 and Cl_2 is therefore indicated. J. H. REEDY

Heats of solution of difficultly soluble electrolytes. II. Determination of the heat of solution of silver iodide at 25.0°. E. LANGE AND Z. SHIBATA. *Z. physik. Chem., Abt. A,* **149,** 465–71(1930); cf. *C. A.* **21,** 1916.—The heat of pptn. of AgI at 25° and 3 different concns. was detd. and the first heat of soln. L_0 calcd. $L_0 = -26.71 \pm .05$ Cal./mol. AgI. This value lies between the uncorr. heats of pptn. of Thomsen $F = 26.44$ at 18° and of Berthelot $F = 26.90$ Cal. at 15°. FRANK URBAN

Studies in the thermochemistry of the compounds occurring in the system CaO–Al_2O_3–SiO_2. IV. The heat of solution of tricalcium aluminate and its hydrates in hydrochloric acid. T. THORVALDSON, WELDON G. BROWN AND C. R. PEAKER. *J. Am. Chem. Soc.* **52,** 3927–36(1930); cf. *C. A.* **24,** 2369.—From the heats of soln. in HCl.-

$20H_2O$ and $200H_2O$, the heat of formation of tricalcium aluminate from CaO and Al_2O_3 is found to be 77 cal./g. at 20°; the heat of hydration to $6H_2O$ is 214 cal_{20} per g. at 20°. ARTHUR FLEISCHER

Energy of $K\alpha_3$ of copper as a function of applied voltage with the double-crystal spectrometer. JESSE W. M. DU MOND AND ARCHER HOYT. *Phys. Rev.* **36**, 799–809 (1930).—With a *specially designed* double-crystal spectrometer the following investigations were made for the purpose of detg. the origin of the satellite $K\alpha_3$ of Cu: (1) dependence of intensity of satellite $K\alpha_3$ of Cu on voltage with const. current; (2) dependence of intensity of parent line $K\alpha_1$ of Cu on voltage with const. current; (3) ratio of intensities of satellite to parent; (4) dependence of satellite intensity on current at const. voltage. Conclusions: (1) The satellite is excited at a voltage differing from the excitation voltage of the parent line by too small an amt. to be measured with certainty (less than 200 v.) (2) The ratio of intensities of α_1 to α_3 as estd. from the areas of the spectral line structure is about 1:120. (3) The intensity of the satellite $K\alpha_3$ of Cu is strictly proportional to the current at const. voltage. Richtmyer's "double jump" hypothesis remains tenable with these facts. A doublet structure in $K\alpha_3$ of Cu was observed (sepn. of components about 2 X. U.). BERNARD LEWIS

Precision measurements in the *K* and *L* series of Cu (29), Sn (50) and the elements from erbium (68) to rhenium (75). INA WENNERLOF. *Arkiv. Mat. Astron. Fysik* **22A**, No. 8, 1–20(1930).—Siegbahn's tube spectrometer, described by Larsson (*C. A.* **21**, 2606), was used to obtain the *K* and *L* series of the x-ray spectra of Cu, Sn, and the elements from Er to Re. The results for the wave lengths, in X units, are presented in comprehensive tables, and are quoted in many instances to 2 or 3 decimal places. For the $K\alpha_1$ line of Cu, *e. g.*, the value 1537.395 was obtained. C. C. KIESS

The atomic scattering powers of nickel, copper and iron for various wave lengths. RALPH W. G. WYCKOFF. *Phys. Rev.* **36**, 1116–20(1930). —Data obtained for the at. scattering powers for the atoms in Ni, Cu and Fe show that the scattering power of an atom passes through a min. at its *K* absorption limit and attains a max. at, or near, its "resonance" wave length. The at. *F* curves of the Ni atom in metallic Ni and in NiO are practically identical. BERNARD LEWIS

X-ray scattering coefficient as a function of wave length and atomic number. ERROL N. COADE. *Phys. Rev.* **36**, 1109–15(1930).—The mass scattering coeffs. for Au, Sn, Ag, Fe and C were compared with those of Al for wave lengths between 0.48 and 1.09 A. U. The scattered radiation was collected in an ionization chamber surrounding the scatterer on one side. The primary beam consisted of characteristic fluorescence radiation excited in radiators of Sn, Ag, Mo and Se by a water-cooled W tube. A table of ratios is given which may be transformed into abs. scattering coeffs. BERNARD LEWIS

An analysis of scattered x-rays with the double-crystal spectrometer. NEWELL S. GINGRICH. *Phys. Rev.* **36**, 1050–9(1930). BERNARD LEWIS

Some precision measurements in the soft x-ray region. M. SODERMAN. *Phil. Mag.* [7], **10**, 600–16(1930); cf. *C. A.* **23**, 1569.—The previous vacuum app. was improved for greater accuracy in adjusting and with new gratings with 300, 900 and 1800 lines per mm. The following wave lengths were detd. and are referred to Cu $L\alpha$ = 13.306 A. U.

Al	$K\beta$	7 952	±0 002 A. U.
Al	$K\alpha_{3,4}$	8 262	.002
Al	$K\alpha_{1,2}$	8 323	.002
Mg	$K\alpha_{3,4}$	9.799	.003
Mg	$K\alpha_{1,2}$	9 874	003
Na	$K\alpha$	11.885	.004
F	$K\alpha$	18 275	.007

The lattice constants of saturated fatty acids of high molecular weight along with the x-ray spectra of some lower elements in the *K* and *L* series. ADOLF KARLSSON. *Arkiv Mat Astron. Fysik.* **22A**, No. 9, 23 pp.(1930).—The lattice consts. for lauric MALCOLM DOLE

palmitic, stearic, laurostearic and cerotic acids, $Pb(C_{31}H_{61}O_2)_2$, $Pb(C_{32}H_{63}O_2)_2$ and Pb palmitate were measured with different x-ray radiations and after different methods of crystn. By means of these crystals, x-ray wave lengths in the *K* and *L* series were measured for the following elements: Zn, Cu, Ni, Co, Fe, Mn, Cr, V, Na, F, O and N. MALCOLM DOLE

Quantitative spectral analysis by means of x-rays. G. v. HEVESY. *Metallwirtschaft* **9**, 801–4(1930); cf. *C. A.* **24**, 1312.—A quant. measure of the intensity of x-ray emission lines enables analyses of substances to be made if addnl. elements are introduced for purposes of comparison. H. discusses the disturbing effect of foreign substances and gives a list of metals and comparison metals whose analyses are comparatively free of error. The detns. of Ti in iron meteorites, traces of Pb in Zn, K in soils, Cb and Ta in volcanic rocks are mentioned as examples. MALCOLM DOLE

The space distribution of x-ray photoelectrons from a solid film. LEWIS SIMONS. *Phil. Mag.* [7], **10**, 387–401(1930).—The distribution of the photoelectrons from a Au film 0.003 in. in thickness when bombarded by x-rays was detd. The results are in agreement with the probability law and the Einstein photoelec. law, which require not only that the max. velocity of ejection should be independent of direction, but also that all unscattered photoelectrons of minor velocities should have the same spatial distribution as the most rapid ones. ARTHUR FLEISCHER

An x-ray investigation of the lead-antimony alloys. D. SOLOMON AND W. MORRIS JONES. *Phil. Mag.* [7], **10**, 470–5(1930).—Pure Sb, Pb, an alloy 70% Sb and 30% Pb, and an alloy 80% Pb and 20% Sb prepd. by Stephens (*C. A.* **24**, 4199) were examd. by the powder method. From the lack of change in the at. diams. in the alloys, it is concluded that the solubilities do not exceed 0.5% by wt. ARTHUR FLEISCHER

Transverse resistance of the oxide-layer of glowing cathodes. JULIUS KROCZEK AND ERNST LÜBCKE. *Wiss. Veröffentlich. Siemens-Konzern* **9**, 252–61(1930).—The resistance encountered by the electrons in passing from the central wire of an oxide-coated cathode to the surface of the cathode was measured in terms of the resp. heating and cooling effects produced on emission of electrons. By establishing an energy balance, the work function was also detd. simultaneously with this transverse resistance. By using a Hg-vapor amplifier tube as a rectifier in connection with a. c., the Maxwellian distribution of electrons was measured. The transverse resistance of the oxide layer was found in all cases to be ohmic in character. Its magnitude depends largely upon the Ba content of the paste used in forming the cathode, and increases both with the thickness of the layer and with the diam. of the individual particles composing the paste. The sp. resistance appears to decrease with increasing temp. according to an exponential law. It seems to lie below the value hitherto found for BaO, probably because of the diffusion of atoms of the alkaline earth metals in the paste back from the surface to the central wire. The least value for the work function was found to be $\phi = 0.945$ v. W. W. STIFLER

Corona discharge in hydrogen. J. H. BRUCE. *Phil Mag.* [7], **10**, 476–80(1930); cf. *C. A.* **22**, 2319.—The starting potentials, potential to maintain current, and the relation between current and applied potential were detd. Some similarities to the case of the monatomic gases were found. ARTHUR FLEISCHER

Some problems of nuclear physics treated according to wave mechanics. A. C. BANERJI. *Phil. Mag.* [7], **10**, 450–64(1930); cf. *C. A.* **24**, 2373, 3164.—The previously developed law of force is applied to the calcn. of the γ-rays of Ra B, Ra C, Th C and C′, MsTh2, RdAct, Act X. In most cases good agreement with expt. is found. ARTHUR FLEISCHER

Note on the photographic counting of α-particles. J. C. JACOBSEN. *Phil. Mag.* [7], **10**, 413–6(1930). The photographic method may be used when the no. of particles is between 10 and 200 thousand per sq. mm. and when the velocity is greater than 0.3 times the velocity of α-particles from Ra C. The chief difficulty is fogging of the plates. ARTHUR FLEISCHER

The capture of electrons by swift α-particles. J. C. JACOBSEN. *Phil. Mag.* [7], **10**, 401–12(1930).—The capture of electrons was measured for H_2 and for air. The exptl. results for H_2 agree with the calcd. when the assumptions are made: (1) the probability of capture in H_2 may be neglected and (2) the equil. state between singly and doubly charged pos. α-particles is the same for mica and for air for the same velocity of α-particles. ARTHUR FLEISCHER

Abnormal shot effect of ions of tungstous and tungstic oxide. JOHN S. DONAL, JR. *Phys. Rev.* **36**, 1172–89(1930). BERNARD LEWIS

Current, pressure and frequency relationships for the initiation and maintenance of the electrodeless glow discharge. MILTON L. BRAUN. *Phys. Rev.* **36**, 1195–1203

(1930).—Crit. current and crit. pressure values for the initiation of a discharge and their relation to the excitation frequency have been investigated by means of the electrodeless glow discharge for H_2, O_2, CO_2 and N_2. The approx. center of the bend on the graph showing the relation between the current necessary to start the discharge and the pressure has been chosen as the crit. point. It was found (1) that the crit. current and crit. pressure vary as the square of the wave length; (2) that the ratio of the crit. current to the crit. pressure is const. for a given gas. The current necessary to maintain the glow was also investigated, and formulas were obtained expressing relationships between maintaining current, initiating current, wave length and pressure. B. L.

Discharge phenomena for slow ions. H. KALLMANN AND B. ROSEN. *Z. Elektrochem.* **36**, 748(1930); cf. *C. A.* **24**, 3707.—Slow ions moving through gases lose their charge if the neutralization energy of the ion nearly equals the ionization energy of the mol. For doubly charged ions, the discharge takes place when the resonance conditions are most favorable for both electrons. A method for detg. the ionization potential of unstable mols. consists in measuring the discharge in several gases. The most intense spectrum is found when the ionization potential of the unknown corresponds to the ionization energy of the known mols. Results for CN and C_2 are approx. 14 and 12 v., resp. G. M. MURPHY

Linear correction for cathode ray oscillograph. FREDERICK BEDELL AND JACKSON KUHN. *Phys. Rev.* **36**, 993–6(1930). BERNARD LEWIS

Heating of electrolytes in high-frequency fields. J. C. MCLENNAN AND A. C. BURTON. *Can. J. Research* **3**, 224–40(1930).—The heating of solns. of simple electrolytes of varying concns. when irradiated by short electromagnetic waves from 10 to 200 m. in length was measured. Solns. of HCl, LiCl, NaCl and KCl were used. No effect was shown with sugar solns., with liquid O_2 or liquid SO_2. Irradiated milk showed no difference in aging properties either of the pasteurized or unpasteurized product. The heating of electrolytes depends on the sp. cond. of the liquid and rises to a max. for a certain cond. The higher the frequency the more marked the max. The cond. at which the max. effect occurs is proportional to the frequency. The sp. cond., dielec. const. and frequency are connected by the law $2C/nK = 1$, where C = sp. cond. in abs. units, K = dielec. const. and n = frequency of wave. "Skin effect" was shown to be negligible, both theoretically and experimentally, for substances having low cond. and deep-seated heating effects were found with the radio waves used. The possibility of directed selective heating effects is suggested and illustrated by expts. on blood. The diclec. const. for water was detd. as 81.7 by use of the law $2C/nK = 1$. J. W. SHIPLEY

The inner lattice potential of natural and yellow sodium chloride. E. RUPP. *Z. Physik* **61**, 587–92(1930); cf. *C. A.* **24**, 1020.—Further expts. were performed on the reflection of electrons of different velocities from crystals of natural and yellow NaCl. The reflection maxima of the yellow NaCl occur at lower electron velocities than those of the natural NaCl. This corresponds to a higher inner lattice potential for the former. The change of lattice potential with coloration is related to the electron mobility within the crystal. Blue NaCl showed no reflection maxima. Synthetic NaCl showed maxima at the same electron velocities as the natural NaCl but of different intensities. P. T. NEWSOME

A method for separation of the barrier film photoelectric effect and the internal photoelectric effect of cells of crystalline semiconductors. H. KERSCHBAUM. *Naturwissenschaften* **18**, 832–3(1930).—Cryst. semiconductors such as Cu_2O show a considerable barrier film photoelec. effect (Duhme and Schottky *C. A.* **24**, 5614). The photoelec potential depends on the barrier resistance; the latter in turn on the d. c. potential applied to the film, decreasing with increase of pos. potential on the semiconductor. The same substances show an internal photoelec. effect which changes in direction by application of potential. A method is given for sep. measurement of both effects. Irradiation of a photoelec. cell of the material by intermittent light allows sep. measurement of the alternating photoelec. potential. A curve of the latter *vs.* applied const. potential shows a decrease with increasing potential (barrier effect predominates up to about 150 to 200 mv., where the barrier resistance, and hence its potential, practically disappear). Further increase of the d. c. potential applied gives again an increase in total photoelec. effect. A second set of curves of the alternating photoelec. effect *vs.* frequency of the exciting light at different potential levels brings out the inertia of the internal photoelec. effect as compared with the lack of inertia in the barrier effect. Up to a pos. potential of 160 mv. practically no inertia is found; from 160 mv. on, the inertia influence rises rapidly. For neg. potentials where the barrier resistance disappears slowly a noticeable inertia is only found below —1.78 v. B. J. C. VAN DER HORVEN

The absorption of slow hydrogen positive rays in hydrogen. ROBERT E. HOLZER. *Phys. Rev.* **36**, 1204–11(1930).—An *exptl. method is described* for studying the absorption of slow hydrogen pos. rays in H_2. The absorption coeffs. of H^+, H_2^+ and H_3^+ in H_2 were measured in the range between 60 and 850 v. BERNARD LEWIS

Thermal electron emission and thermal electromotive force. M. v. LAUE AND GÖSTA SILJEHOLM. *Naturwissenschaften* **18**, 764–5(1930).—During measurements of the thermal electron emission current of Fe it was found that near the A_3 transition point ($\beta-\gamma$ iron) ($T = 1183°$ abs.) a relation exists between this current and the thermal e. m. f. of Fe against Pt. It is shown that thermodynamically a relation can be derived: $e_{Pt\beta} - e_{Pt\gamma} = (R/C) \ln (i_\beta/i_\gamma)$ for e the thermal e. m. f., i the electron satn. current, the value of R/C being $3.8.10^{-5}$ for e in v. per degree. Log i_β/i_γ was measured at the transition point and found to be 0.33 ± 0.03. Hence $e_{Pt\beta} - e_{Pt\gamma} = 1.25.10^{-5}$ v. per degree, found by S. $1.2.10^{-5}$, by Burgess and Scott (*Bull. Bur. Standards* **14**, 15 (1918)) $0.9.10^{-5}$ v. per degree (± 30%). The agreement shows the validity of several of the theorems utilized. B. J. C. VAN DER HOEVEN

Distinction between contact-potential effects and true reflection coefficients for low-velocity electrons. H. E. FARNSWORTH AND V. H. GOERKE. *Phys. Rev.* **36**, 119–94 (1930). BERNARD LEWIS

The scattering of fast electrons by metals. I. The sensitivity of the Geiger point-discharge counter. CARL T. CHASE. *Phys. Rev.* **36**, 984–7(1930).—C. presents new information on the sensitivity of the Geiger point-discharge counter. **II. Polarization by double scattering at right angles.** *Ibid* 1060–5; cf. *C. A.* **24**, 1019. B. L.

The velocity distribution of secondary electrons from molybdenum. THEODORE SOLLER. *Phys. Rev.* **36**, 1212–20(1930). BERNARD LEWIS

Reflection of cadmium and zinc atoms from sodium chloride crystals. HAROLD A. ZAHL. *Phys. Rev.* **36**, 893–903(1930).—A specularly reflected beam of Zn atoms from a NaCl crystal was investigated (1) by measuring the velocity distribution of the atoms composing the specular beam; and (2) by examg. the specular beam after reflection from a second crystal. A difference in angle of 22.5° between the 2 crystals does not greatly reduce the intensity of the specular beam. It is concluded that if velocity selection or a space-grating type of reflection of Zn is present it is not very pronounced. Double-reflection expts. of Cd from NaCl crystals have been repeated and apparently evidence for both space and surface-grating phenomena has been found in certain cases. It is suggested that individual differences in crystals may be an important factor in causing these differences. BERNARD LEWIS

Angle and energy distribution of electrons scattered by helium, argon and hydrogen. J. HOWARD MCMILLEN. *Phys. Rev.* **36**, 1034–43(1930).—The distribution of electrons rebounding at definite angles from gas mols. was investigated. The following energy losses at several angles were identified in He: 21.12, 22.97 and 23.52 v. for a primary electron beam of 50 v.; 19.77 and 20.55 v. losses were not found. The no. of electrons rebounding without loss of energy was measured for different angles of rebound (7° to 60°) from A, He and H_2 mols., and for various energies (50 to 150 v.). A scattering curve was also obtained in He for 100 v. electrons that had lost 21.12 v. energy. In nearly all cases, the no. scattered decreased rapidly as the angle increased. The higher the energy of the electrons, the more rapidly did the no. fall off with increasing angle. The steepness of the curve increases as one goes from A to He to H_2 for the slower electrons. For the faster electrons their curves are practically superposable. The results were compared with those of other observers and with the theoretical predictions of Mott, Mitchell and Sommerfeld. BERNARD LEWIS

The temperature radiation of non-metallic bodies, especially oxides. FRANZ SKAUPY AND GERHARD LIEBMANN. *Z. Elektrochem.* **36**, 784–6(1930); cf. *C. A.* **24**, 5222.—Lowering the grain size in a non-metallic body radiating selectively causes an increase in its absorptive power over the whole spectral region so that a fine-grained body has equal or better selectivity than a single crystal of the same material. Curves are given for Al_2O_3 and ThO_2. J. B. AUSTIN

Ionization potential of radon. F. HOLWECK AND L. WERTENSTEIN. *Nature* **126**, 433(1930).—Using a modified form of Hertz' method, the authors give curves for Kr, Xe and Rn, the ionization potentials being 13.3, 11.4 and 10.6 v., resp.; the latter were in good agreement with the value of 10.7 deduced by Rasmussen from spectral data. LOUIS WALDBAUER

Quantum transitions by collisions of the second kind. H. BEUTLER AND W. EISENSCHIMMEL. *Z. Elektrochem.* **36**, 746–7(1930).—For collisions between atoms in a singlet and triplet state, resp., the most probable result is that the multiplicity of the whole system remains unchanged. A weak discharge was passed through 3 mm. He,

satd. with Hg at room temp. (0.002 mm.) and Kr added from 0.004 to 0.5 mm. Measurements of the intensity of the emitted radiation show that the probability of excitation of the triplet states is greater than that of the singlet states by a factor of 15–30.

Spectrum of xenon in the ultra-violet (2700–1850 A. U.). GEORGES DÉJARDIN. *Ann. phys.* [10], **14**, 82–93(1930).—The spectrum of Xe, excited by means of an electrodeless discharge, was observed in the ultra-violet. The exptl. procedure and app. have been previously described (*C. A.* **22**, 726). The spectrum was found to consist of lines emitted by singly, doubly and trebly ionized atoms. The wave lengths which were measured, and of which more than 350 are new, extend from 2734 to 1873 A. U., and are presented in the tables together with the designation of their ionic origin.
C. C. KIESS

The arc spectrum of nitrogen. ERIK EKEFORS. *Z. Physik* **63**, 437–43(1930).—A discharge tube contg. N and He was used as a light source. The spectrum of N was photographed with a vacuum spectrograph of 1-m. radius and the wave lengths of 137 lines (1008.875 A. U. to 1889.056 A. U.) were measured. About half of the lines are classified as combinations of doublet or quartet terms. Intersystem combinations are found which fix the relative positions of all terms. The highest term is $(2p^2.np)^4S^\circ_{1/2} = 117{,}345$.
W. F. MEGGERS

The line spectra of ions in the solid state in the visible and ultra-violet regions of the spectrum. The absorption spectra of $GdBr_3 \cdot 6H_2O$ at room temperature and at that of liquid air, and their comparison with those of $GdCl_3 \cdot 6H_2O$. SIMON FREED AND FRANK H. SPEDDING. *J. Am. Chem. Soc.* **52**, 3747–56(1930).—The possibility of applying the quantum theory of the line spectra of gases to ions in the solid state suggested investigation of the spectra of rare earth ions. The absorption spectra of the crystal $GdBr_3.6H_2O$ were photographed with a quartz spectrograph, a H-discharge tube being used as a source of continuous spectrum. About 50 absorption lines are found between 2441 and 3110 A. U.; even at room temp. these lines are extremely sharp. There is complete parallelism between spectra of $GdBr_3 \cdot 6H_2O$ and $GdCl_3 \cdot 6H_2O$ (cf. *C. A.* **24**, 1023). The displacement toward the red and the greater sepn. in the former can be related to the greater deformability of the Br ion. W. F. MEGGERS

Methods of interpreting and predicting molecular spectra. F. HUND. *Z. Elektrochem.* **36**, 596–9; *Physik. Z.* **31**, 876–80(1930). W. F. MEGGERS

The spectra of solidified gases and their theoretical atomic meaning. L. VEGARD. *Ann. Physik* [5], **6**, 487–544(1930).—Results of work during 6 years on the spectra of solidified gases in liquid H_2 and He with special reference to the spectra of N_2 and N_2-rare gas mixts. are given. Excitation was by means of cathode rays from 100 to 30,000 v. and canal rays. Doublet and triplet lines, sharp and diffuse bands compose 6 series that are considered in detail. Intensity distributions are discussed in connection with the theory of Condon. The emitters are solid α-N_2 and NO, dissocn. energy and values being calcd. for the electronic transitions and for the vibrational const. The energy levels are detd. by comparison with the Mg^+ spectrum for N_2 and with the Al^{++} spectrum for NO. The solid N_2 states are compared with those for gaseous N_2. G. M. MURPHY

The interpretation of a type of diffuse band spectra. HEINRICH KUHN. *Z. Physik* **63**, 458–76(1930).—Besides the predissocn. spectra first observed by V. Henri there is still another type of diffuse bands having a different appearance and a different explanation. The general features are, in addn. to absence of band heads, the occurrence of only a single progression of bands as if only the initial or the final term had different vibration states; the interval between bands is often greater than the largest vibration quantum of the mol.; the interval between bands decreases abnormally rapidly and the bands become narrower. The spectra which result from the combination of a firmly bound mol. state with a loosely bound state are considered and it appears that the Franck-Condon principle in consequence of the flatness of one of the potential curves leads to a general explanation of the diffuse bands. The diffuse bands of Tll, AgI, AgBr, Hg_2 and I_2 are discussed and interpreted. W. F. MEGGERS

Evidence from band spectra of the existence of carbon isotope of mass 13. ARTHUR S. KING AND RAYMOND T. BIRGE. *Astrophys. J.* **72**, 19–40(1930).—Evidence of the existence of this isotope, C^{13}, appeared first in a faint band structure with head at 4744.5 A. U., showing on elec.-furnace spectrograms in which the Swan band at 4737 A. U. was of high intensity (cf. *C. A.* **23**, 4879). The quantum theory of band spectra showed that the band at 4744.5 A. U. was due to a $C^{13}C^{12}$mol., the emitter of 4737 A. U. being a $C^{12}C^{13}$ mol. Further exptl. work, together with examn. of older material, shows that C^{13} enters into mols. producing isotopic bands connected with the Swan band at 4383 A U., the cyanogen bands at 3883 and 3590 A. U. and the CO bands between 1200 and 1500 A. U. The relative abundance of C^{13} and C^{12}, estd. very roughly from photographic intensities of the bands, appears to be of the order 1:400. Such estimates are rendered uncertain, however, by an apparent dependence on the method of excitation. The furnace and other low-excitation sources, notably N-type stars, are very effective in emitting the C^{13} spectrum. In the arc the only evidence of C^{13} thus far is a group of lines in the cyanogen band at 3883 A. U. W. F. MEGGERS

Molecular ray experiments. The chemical activity of molecular and atomic oxygen. WORTH H. RODEBUSH AND W. A. NICHOLS, JR. *J. Am. Chem. Soc.* **52**, 3864–8(1930).—An exhaustive search failed to discover any surface with which a beam of O mols. will react to give a visible image. A beam of at. O appears to give the same product on reaction with MoO_3 as does a beam of at. H. The reaction is believed to be $3MoO_3 + O = Mo_3O_8 + O_2$. J. B. AUSTIN

Intensities in the spectra of diatomic molecules with uncoupling of the electron-orbit impulse. R. DE L. KRONIG AND Y. FUJIOKA. *Z. Physik* **63**, 168–74(1930).—The intensity relations in the spectra of diat. mols. are investigated theoretically for the case in which, on account of the rapid rotation of the nuclei, the orbital impulse of the electrons is no longer quantized on the line joining the nuclei. Band spectrum

analysis shows that this occurs in light mols. like H_2 or He_2. The theoretical results are compared with exptl. measurements in another paper (cf. following abstr.). W. F. M.

Intensities in He_2 bands with uncoupling of the electron-orbit impulse. Y. FUJIOKA. *Z. Physik* **63**, 175–87(1930).—Analysis of the He_2 spectrum has shown that for certain higher states of this mol. the electron-orbit impulse is not firmly coupled to the line joining the nuclei. The energy values then deviate from those given by a Deslandres formula, and the relative intensities are affected. A quant. theory of intensities in such a case is developed in another paper (cf. preceding abstr.). The present paper gives quant. intensity measurements in a considerable no. of bands in the single and triplet system of He_2; a satisfactory agreement with the theoretical predictions is found (cf. *C. A.* **23**, 1571). W. F. MEGGERS

The Zeeman effect in the ZnH and CdH bands. WILLIAM W. WATSON. *Phys. Rev.* **36**, 1134–43(1930). BERNARD LEWIS

Intensity measurements in the band spectrum of mercuric hydride. II. JOHANNA G. EYMERS. *Z. Physik* **63**, 396–401(1930).—In an earlier publication (Kapuscinski and Eymers, *C. A.* **23**, 3629) intensity measurements in 8 bands of the HgH spectrum were given. Results are now given for 3 addnl. bands designated as 4050, 4150 and 3647 A. U. W. F. MEGGERS

The origin of the bands in the spectrum of mercury vapor. S. MROZOWSKI. *Phys. Rev.* **36**, 1168–71(1930).—M. points out that the contradictions pointed out by Rollefson (*C. A.* **24**, 5228) do not exist and draws a no. of conclusions from the exptl. facts concerning the origin of absorption and emission bands in the spectrum of Hg vapor. A new observation is made of shaded absorption bands at 2267 and 2247 A. U. B. L.

Study of the continuous band spectra of mercury and zinc vapors. H. VOLKRINGER. *Ann. phys.* [10], **14**, 15–81(1930).—The vapors of Hg and Zn in fused quartz tubes were observed to emit continuous band spectra when excited by an electrodeless discharge. At low pressures ranging from that of the vapor at room temp. to that at 90°, a continuous spectrum appears in Hg extending from about 2000 A. U. to the red. Temp. changes do not affect the appearance of this spectrum. At higher pressures, up to that of the vapor at 120°, the continuous band undergoes a change in distribution of intensity, 2 max. appearing at 2537 and 2265 A. U. At pressures within the tube of 4 or 5 cm. the discharge excites a spectrum consisting of arc lines, several narrow bands, and a broad band beginning sharply at the resonance line of Hg I and extending to the red. The distribution of intensity within the bands obtained from microphotometer measurements is shown by means of curves. Similar results obtained with Zn vapor are also described in detail but have been reported previously (*C. A.* **24**, 1290). C. C. KIESS

The structure of the absorption bands of tellurium. A. PRZEBORSKI. *Z. Physik* **63**, 280–6(1930).—Two series of absorption bands characteristic of Te_2 mols. are photographed by sending white light through a quartz tube 1 m. long contg. Te heated to 450° or 550° in an elec. furnace. The bands extend between 5393 and 5405 A. U. and between 5357 and 5368 A. U.; their convergence limits are extrapolated to 5364.7 and 5336.2 A. U., resp. In the normal state the moment of inertia of the Te_2 mol. is calcd. to be 8.63×10^{-38} g. sq. cm., and the distance between atoms is 2.87×10^{-8} cm. W. F. MEGGERS

Canal ray and electron excitation of the band spectrum of nitrogen. H. D. SMYTH AND E. G. F. ARNOTT. *Phys. Rev.* **36**, 1023–33(1930). BERNARD LEWIS

Theory of the Raman effect. E. AMALDI AND E. SEGRÈ. *Atti accad. Lincei* [6], **9**, 407–9(1929); cf. *C. A.* **24**, 2040. E. J. C.

Raman spectra under high dispersion. W. M. DABADGHAO. *Indian J. Physics* **5**, 207–17(1930).—A Hilger E_1 spectrograph was used to photograph the Raman spectra of C_6H_6, $CHCl_3$ and CCl_4. The results obtained for the shifted lines are presented in tables in comparison with those by other investigators. In addn. to the greater precision attained in the wave lengths the higher dispersion of the spectrograph enables other features of the Raman spectrum to be observed, *e. g.*, the winged nebulosity accompanying the unmodified lines. C. C. KIESS

Raman spectra of the mercaptans. S. VENKATESWARAN. *Indian J. Physics* **5**, 219–36; *Nature* **126**, 434(1930).—The Raman spectra of the following mercaptans were excited by various Hg lines: Me, Et, Pr, Bu, isobutyl, isoamyl and Ph. The results of the observations are presented in detail in the tables. It is seen that all exhibit the frequency shifts 2573, 739 and 657, in common, of which the former is attributed to the SH oscillation, and the two latter to the oscillations of the CS group. The 2573

shift has been observed in H_2S also. It is analogous to the 3400 cm.$^{-1}$ shift of OH, which, however, has been observed only in H_2O and CH_3OH but not in the higher alcs. C. C. KIESS

Raman spectral of crystalline inorganic chlorides. P. KRISHNAMURTI. *Indian J. Physics* 5, 113–28(1930).—The method devised for observing the Raman spectra of the inorg. nitrates (*C. A.* 24, 3439) has been applied to the inorg. halides. The details of the investigation are tabulated. It was found that the chlorides of strongly electro-pos. elements do not show Raman lines, whereas those of the non-metals and metalloids do. The compds. showing the effect are either non-conductors or feeble conductors. Good conductors do not show the effect at all. The observations lead to the conclusion that covalent bonds are necessary for the Raman effect, compds. in which only electrovalent bonds are present failing to exhibit the effect. C. C. K.

Interpretation of Raman spectra: some aliphatic amines and alcohols. S. VENKATESWARAN AND S. BHAGAVANTAM. *Indian J. Physics* 5, 129–43(1930).—The results obtained in a study of the Raman effect of some lower members of the aliphatic amines and of some of the alcs. are presented in detail. $MeNH_2$, $EtNH_2$ and Et_3N all exhibit a Raman line at $\Delta\nu$ = 1050 cm.$^{-1}$ which is attributed to the C—N linkage. $MeNH_2$ and $EtNH_2$ also have a frequency of about 3300, absent in triethylamine, which is attributed to the N—H linkage. The alcs. and fatty acids exhibit 3 frequencies in common about 1050, 1250 and 1360 cm.$^{-1}$ which are attributed to the $-\overset{|}{\underset{|}{C}}-OH$ group, while the $-\overset{O}{\overset{\|}{C}}-$ group in the fatty acids is responsible for the frequencies 600 and 1700 which are not present in the alcs. Comparison of the paraffins with the alcs. and acids reveals a common frequency of 900 due to the C—C linkage, the line showing structure with increasing complexity of the C chain. C. C. KIESS

Raman effect in some organo-metallic and heterocyclic compounds. S. VENKATESWARAN. *Indian J. Physics* 5, 145–58(1930).—Observations of the Raman effect for $Zn(CH_3)_2$, $Zn(C_2H_5)_2$, C_4H_4S and C_4H_4NH are presented in detail. The 2 org.-metallic compds. exhibit 5 frequencies in common, of which 2 are attributed to the C—H linkage and the other 3 to the oscillations between the org. and metal groups. $Zn(C_2H_5)_2$ exhibits 2 addnl. frequencies, not present in $Zn(CH_3)_2$, which are attributed to the C chain. Although C_4H_4S and C_4H_4NH exhibit many Raman lines only one of frequency 1374 appears to be common to both and is attributed to the C=C linkage. Other frequencies of both compds. are traced to the oscillations of the C—H linkage. A study of the polarization of the Raman lines shows that those which are well polarized are also the most intense. C. C. KIESS

The intensities of the lines in Raman spectra. S. C. SIRKAR. *Indian J. Physics* 5, 159–68(1930).—A method of photographic photometry was used to measure the relative intensities of the displaced and undisplaced lines in the spectrum scattered by CCl_4. It was found that for all the shifted lines taken together the ratio of the intensity to that of the undisplaced line is about 1/150. For the Raman lines scattered by the Hg lines 3132 and 4046 A. U. compared with those scattered by 4358 A. U. the intensities were found to be 1.38 and 1.17 times, resp., those required by Rayleigh's 4th-power law. C. C. KIESS

Relation of Raman effect to crystal structure and properties of diamond. S. BHAGAVANTAM. *Indian J. Physics* 5, 169–82(1930); cf. *C. A.* 24, 4987.—The Raman line scattered by diamond corresponds to a frequency shift of 1331.9 cm.$^{-1}$. In addn. there is present in the scattered spectrum a system of 3 bands at 4131, 4157 and 4174 A. U., which do not represent a Raman transition, and a continuous spectrum extending from 4240 A. U. to the red. Regarding each atom in the crystal as in tetrahedral relationship to its neighbors and capable of oscillation with respect to the rest of the lattice, calcn. shows that there are 4 fundamental oscillation frequencies with wave nos. 440, 780, 1306 and 1750, of which the 3rd is in approx. agreement with the observed Raman shift. This is attributed to the vibration of the central C atom within the tetrahedron. C. C.

Raman effect in some crystalline inorganic sulfates. Influence of paramagnetis on Raman lines. P. KRISHNAMURTI. *Indian J. Physics* 5, 183–91(1930).—The powder method (*C. A.* 24, 3439) was used to observe the Raman spectra of 15 inorg. sulfates, the exciting line being Hg 4358 A. U. In all cases except ferrous and Ni sulfates a shifted line was observed at $\Delta\nu$ = 985 cm.$^{-1}$ corresponding to an infra-red line at 10μ. Many of the sulfates also showed shifted lines corresponding to 9, 16 and 22μ. The 2 sulfates in which the 10μ line is weak are both strongly paramagnetic. Those

in which 10μ is strong are diamagnetic. The intrinsic magnetic field due to the cation is apparently responsible for the weakness or absence of the 10μ line. It was found that for sulfates with cations in the same group in the periodic table there was a shift in the position of the 10μ line with change in ionic size when similarly hydrated.
C. C. KIESS

Raman spectra of inorganic sulfates and nitrates. C. RAMASWAMY. *Indian J. Physics* **5**, 193–206(1930).—The Raman spectra of aq. solns. of inorg. sulfates showed wave no. shifts 457, 617, 981 and 1102 cm.$^{-1}$, attributable to the sulfate ion. Aq. solns. of inorg. nitrates gave the shifts 726, 1048 and 1357 cm.$^{-1}$, attributable to the nitrate ion. The 4 frequencies observed for the sulfate ion are fundamental oscillations of which 2 are active and have been observed in infra-red spectra. Two of the frequencies observed for nitrate correspond to active oscillations of the group and have been observed in infra-red spectra. The appearance of the inactive oscillations of the ions as strong lines in Raman spectra is attributed to the high statistical wt. of that transition which involves no change in the elec. moment after the excitation process.

Calibration of standard lamps for relative and absolute measurements. L. S. ORNSTEIN, D. VERMEULEN AND E. F. M. VAN DER HELD. *J Optical Soc. Am.* **20**, 573–84(1930).—Descriptions of 2 methods are given: (1) the photographic, which is independent of temp. measurement, and (2) pyrometric, made by means of a pyrometer. Agreement of 1–2% is obtained by the methods in the spectral region 7000–4000 A. U. Both systems are discussed in some detail, with especial emphasis on exptl. details.
WILLIAM E. VAUGHAN

Kinetics of the thermal transformation of para-hydrogen. A. FARKAS. *Z. Elektrochem.* **36**, 782–4(1930).—H_2 contg. 48% para-H was passed into a quartz vessel contained in an elec. furnace. As the surface of the vessel had no effect, the reaction is homogeneous; the time required for the same percent inversion is inversely proportional to the square root of the pressure, which corresponds to the mechanism: $H_2^p + H \rightleftarrows H_2^o + H$, where H_2^p and H_2^o correspond to para- and ortho-H mols. and H to atoms from thermal dissocn. The mechanism may be pictured thus: a H mol. collides with a H atom. In certain collisions, the H atom changes places with one of the H atoms in the mol. In this way ortho- and para-H_2 are formed in the ratio of 3:1. From the collision yield, the heat of activation of the reaction was calcd. as 11,000 cal. From the temp. coeff. of the reaction, the value is 4200 cal., a value considered as being in fair agreement, considering that the main effect of the increase of speed of reaction with temp. is due to the great increase in H atom concn., while increase in collision yield due to the relatively small heat of activation has only a small effect on the velocity.
LOUIS WALDBAUER

Action of high-speed electrons on methane, oxygen and carbon monoxide. J. C. MCLENNAN AND J. V. S. GLASS. *Can. J. Research* **3**, 241–51(1930).—CH_4, CH_4-O_2 mixts., CO and CO-CO_2 mixts. were exposed to the action of x rays. CH_4 gave small quantities of H_2 and C_2H_6. While CH_4-O_2 mixts. gave as gaseous products CO, CO_2 and H_2 together with H_2O and HCOOH. The relative proportions of the products did not vary widely under a wide variation of conditions. The reaction was of the 1st order in respect to pressure. The rate of reaction increases linearly with the voltage up to a certain value after which it becomes nearly independent of the voltage. The action of cathode rays on CO produces CO_2 and a solid brown suboxide $(C_3O)_n$ very sol. in H_2O. Moist CO gave no solid and less CO_2, while CO-O_2 mixts. under the action of cathode rays gave CO_2. H_2O vapor retarded the reaction. For mixts. of the same compn. the reaction rate was proportional to the total pressure. For dry mixts. the product increases with the CO present; in moist mixts. it is much less and independent of the CO. A brief theory of the reactions is given.
J. W. SHIPLEY

Chemical action in the glow discharge. V. The oxidation of hydrogen. A. KEITH BREWER AND J. W. WESTHAVER. *J. Phys. Chem.* **34**, 2343–55(1930); *cf. C. A.* **24**, 5238.—The rate of synthesis of H_2O from H_2-O_2 mixts. has been studied in a glow discharge between pressures of 0.05 mm. and 35 mm. Between 7 mm. and 0.3 mm. the synthesis occurs predominantly in the neg. glow at a rate independent of the gas pressure. The max. rate of reaction at 3.5 mm. pressure occurs with a gas contg. 87.5% H_2 and 12.5% O_2. At pressures below 7 mm. the reaction is believed to be initiated entirely by H_2^+ ions, while at higher pressures, O_2^+ ions, N_2^+ ions and A^+ ions are

effective as reaction nuclei. An M/N ratio of 4 is obtained in the neg. glow. A proposed mechanism involving ionic clusters in the neg. glow and an ionic chain reaction in the pos. column is in agreement with the data obtained. PAUL H. EMMETT

New experimental determination of effective cross-sections for the quenching of mercury resonance radiation. M. W. ZEMANSKY. *Phys. Rev.* **36**, 919–34(1930).—The problem of the quenching of resonance radiation by foreign gases is treated on the basis of Milne's theory of diffusion of radiation extended to take account of (1) a collimated incident beam, (2) a finite emission line, (3) a finite absorption line and (4) impacts of the second kind; and a curve is obtained from which one can find the no. of impacts of the 2nd kind corresponding to any experimentally observed value of the quenching. The effect of metastable atoms is discussed and a theory of their behavior outlined. Measurements were made of the quenching of Hg resonance radiation and the effective cross-section for quenching was calcd. for the following gases: O_2, H_2, CO, NH_3, CO_2, H_2O, N_2, CH_4, C_2H_6, C_3H_8, C_4H_{10}, He and A. These values are tabulated together with those for depolarization of resonance radiation and for collision broadening. The quenching cross-section of CO, NH_3, CO_2, H_2O, N_2, CH_4, C_2H_6 and C_4H_{10} are shown to be connected with the difference between the energy of the transition $2^3P_1 \longrightarrow 2^3P_0$ and the vibrational energy of the mols. in qual. agreement with the theory of Kallmann and London. BERNARD LEWIS

The quenching of mercury resonance radiation. I. The saturated hydrocarbons. JOHN R. BATES. *J. Am. Chem. Soc.* **52**, 3825–32(1930).—The quenching of Hg resonance radiation by CH_4, C_2H_6, C_3H_8 and C_4H_{10} has been measured and values of the effective collision cross section have been calcd. CH_4 quenches to the metastable level. J. B. AUSTIN

The photochemical reaction between hydrogen and carbon monoxide in the presence of excited mercury atoms, and the optical identification of the reaction products. W. FRANKENBURGER. *Z. Elektrochem.* **36**, 757–69(1930); cf. *C. A.* **23**, 3206.—Mixts. of H_2 and CO react at ordinary temps. and pressures in the presence of Hg atoms optically excited by absorption of 2356 A. U. with the formation of HCHO and $(CHO)_2$. The yields vary with the purities of the reacting gases, their rates of flow, the compn. of the mixts. and temp. of the gases, as well as with the concn. of the Hg vapor, but reach optimum values. $\frac{\text{no. of aldehyde groups formed}}{\text{no. of absorbed quanta 2356 A. U.}} \sim 1$ to 1.5, depending on the source of the radiation (arc or hot cathode type of lamp). The reaction is not a chain reaction, but a reaction involving H atoms and HCO radicals, with the formation of HCHO and $(CHO)_2$ as proved by absorption spectra. The neg. temp. coeff. of the reaction is due to the low heat of formation of the radical HCO from H and CO (—4 cal.). I. J. P.

Photochemical sensitization in the ultra-violet. L. FARKAS, F. HABER AND P. HARTECK. *Z. Elektrochem.* 36, 711–4(1930); cf. *C. A.* **24**, 3173, 4711.—A summary of previous work. I. J. PATTON

Quenching of the fluorescence of nitrogen dioxide. WARREN P. BAXTER. *J. Am. Chem. Soc.* **52**, 3920–7(1930).—The intensity of fluorescence excited in NO_2 by the Hg lines at 4358 and 4047 A. U. has been detd. from 0.001 to 18 mm. NO_2 is very efficient as a quenching agent. Calcns. indicate a deactivational diam. approx. 10 times greater than kinetic theory values. CO_2, N, O and H show specificity in quenching. J. B. A.

The influence of drying on the photolysis of carbon dioxide. ALFRED COEHN AND THEODOR SPITTA. *Z. physik. Chem.*, Abt. B, **9**, 401–25(1930).—In confirmation of previous work (cf. *C. A.* 10, 2549) it is shown that ultra-violet light causes only 1% dissocn. in CO_2 dried over H_2SO_4, whereas, after a long flow over P_2O_5, 20% dissocn. is found. CO_2 formed from CO and O dried with liquid air gives only 1% dissocn., which rises to 10.5% when a very small quantity of moisture is added. A decompn. of 20% was cut to 5% by further drying. The optimum decompn. (at 300 mm.) appears to be about 20% and occurs when a little moisture is present. J. B. AUSTIN

Spectroscopic determination of the equilibrium between nitric acid, nitrogen monoxide and nitrogen dioxide. E. ABEL, H. SCHMID AND M. STEIN. *Z. Elektrochem.* **36**, 692–700(1930); cf. *C. A.* **24**, 3157. W. F. MEGGERS

Measurements of the fluorescence of cellulose acetate, cellulose nitrate and gelatin in ultra-violet light. JAMES G. MCNALLY AND WALDEMAR VANSELOW. *J. Am. Chem. Soc.* **52**, 3846–56(1930).—The intensity of fluorescence of cellulose nitrate and acetate films depends on the wave length of the exciting radiation and on the chem. compn. and micellar structure of the film. The intensity for acetone solns. of cellulose acetate is independent of the colloidal properties of the soln. A decrease in viscosity causes a decrease in intensity for gelatin solns. J. B. AUSTIN

Tribothermoluminescence. R. E. NYSWANDER AND BYRON E. COHN. *Phys. Rev.*

36, 1257–60(1930).—Light of low intensity is emitted when glass, certain crystals and frits are subjected to grinding. A polarization photometer was used to measure the light intensity quantitatively from particles of 20 to 200 mesh. The results show that the quantity of light emitted depends on the substance and its size and diminishes slowly with the time following grinding. The max. quantity of light emitted by ground common glass tubing took place when the linear dimensions of the av. mesh size fell between 0.015 cm. and 0.025 cm., resp. BERNARD LEWIS

The temperature radiation of uncolored oxides in the visible. GERHARD LIEBMANN. *Z. Physik* **63**, 404–36(1930).—A new simple method of pyrometric temp. measurement of bodies of unknown radiation characteristics is developed and compared with the earlier methods. To lay the foundations for this method the visible emissivity of a no. of uncolored oxides (Al_2O_3, MgO, BeO, ThO_2, Cr_2O_3) is investigated as to dependence on temp., wave length, grain size and emission angle. W. F. M.

New investigations of the extinction of calcium phosphores, with especial consideration of mixed phosphores. FRITZ BANDOW. *Ann. Physik* [5], **6**, 434–57(1930); cf. *C. A.* **23**, 3165.—Different methods of prepg. CaSBi-α-phosphores have little effect on the max. of the long-wave extinction; other properties change noticeably. Total amt. of light, distribution of centers and extinction were investigated for pure sulfide and oxide phosphores as well as oxide-sulfide mixts. G. M. MURPHY

Preparation of luminescent substances. N. F. ZHIROV. *Zhur. Prikladnoĭ Khim.* **3**, 675–80(1930); cf. *C. A.* **23**, 3624.—H_3BO_3 was purified by crystn. from concd. HNO_3 contg. H_2O_2. Luminophores are easily obtained and may be prepd. during the lecture hrs. Optimum concn. of fluorescein (activator) is 1:10,000. Below this optimum the spectrum shifts toward violet, while above this optimum it shifts toward red. Intensity increases until the optimum is reached but is unchanged for higher concns. of the activator. Triphenylmethane gives a weak yellow luminescence. Complex luminophores show no improvements in properties, probably because of differences in the structure of the fluorescent centers of sulfides and H_3BO_3. Phosphorescence of H_3BO_3 with fluorescein can be used as a qual. test for H_3BO_3. As little as 1/50 mg. of H_3BO_3 can be thus detected. These luminophores are characterized by their sensitivity to even weak sources of light. V. KALICHEVSKY

COLIN G. FINK

Electric resistance furnaces for the chemical industry. ERNST SCHMIDT. *Chem. Fabrik* **1930**, 409–10, 425–6.—The Wild-Barfield furnace for tempering C steels is described. J. H. MOORE

Electric smelting of sulfur-rich ores. AXEL WEIJNARTH. *Medd. Sveriges Kem. Ind.-Kontor* **13**, 85–103(1930).—An address on electrometallurgy. Tables and graphs give the cond. of systems of sulfides and silicates at smelting temps. A. R. ROSE

Artificial atmospheres in electric furnaces. A. J. STRAIN. *Can. Chem. Met.* **14**, 290–2(1930).—A process has been developed which involves the complete or partial thermal decompn. of hydrocarbons with or without steam to produce mixts. having CO, H_2 and CO_2 as the main constituents. The relative quantities of gases in the mixt. will depend upon: (1) the hydrocarbon being treated; (2) the temp. to which it is heated; and (3) the amt. of steam used. The choice of raw material depends upon: (1) its availability; (2) the use to which the electrolene is to be put; and (3) its effects upon the final cost of the electrolene. The raw materials necessary for the production of electrolene are gas, steam and elec. energy. Twelve advantages claimed for the electrolene producer over all other com. app. are listed. Several tables and illustrations are included. W. H. BOYNTON

Electrolytic extraction of tin and copper from scrap bronze. O. SCARPA. *Bull. soc. franç. electriciens* **10**, 572–9(1930); *Chimie & industrie* **24**, 608(1930).—Scrap bronze

is melted and cast into plates which are used as sol. anodes in the electrolysis of a H_2SO_4 soln. of $CuSO_4$. In order to maintain the compn. of the electrolyte const., part of it is circulated continually through tanks where the colloidal Sn oxide is coagulated by heating. After decanting, the soln. is passed through a tower filled with Cu shot through which is also passed a current of air and steam, thus forming $CuSO_4$ again from the H_2SO_4 liberated by hydrolysis of $SnSO_4$. The $ZnSO_4$ and $FeSO_4$ which accumulate in the soln. interfere only when present in large quantities. Cu of 99.97% purity is obtained with a power consumption of 0.665 kw. hr. per kg. of Cu. The Sn sludge is treated with NaOH, the stannate soln. is treated chemically to remove Pb, Zn and Sb, and it is then electrolyzed giving a very pure spongy Sn, which only requires to be remelted.

Hydrogen overvoltage. I. Cathodic hydrogen evolution at low current density and the question of the least overvoltage. ERNST BAARS AND CARL KAYSER. *Z. Elektrochem.* **36**, 428–39(1930); cf. *C. A.* **24**, 4715.—Suitable app. is described for these measurements. Below a certain c. d. on certain metals the quantity of evolved H falls below that required by Faraday's law. This deficiency may be due to several factors such as soly., diffusion, convection, etc., but some may be dissolved in the electrode material. C. J. B.

The electrodeposition of nickel and chromium on zinc die castings. SAMUEL GORDON. *Metal Cleaning and Finishing* **2**, 765–6(1930).—In prepg. Zn die castings for Ni and Cr plating only such castings that are free from pin holes and will finish to a smooth, non-porous surface should be chosen. After being polished, the castings are cleaned electrolytically by immersion in any good cleaner for 15 sec. at about 65°. When rinsed in cold water they are flash plated in a brass soln. of the following compn.: water 1 gal., NaCN 4.5 oz., Cu cyanide 3 oz., $Zn(CN)_2$ 1 oz., Na_2CO_3 2 oz., aq. NH_3 1 qt. to each 100 gals. of soln. Ni may be plated directly on the non-porous metal, but it has been found that a light coat of brass prolongs the life of the finish. If Ni is plated directly, the castings should be cleaned and rinsed as before and then dipped in 20% HF. After being rinsed in water they are plated 4–5 min. at 26° in a Ni soln. of the following compn.: water 1 gal., single Ni salts 6 oz., double Ni salts 2 oz., NaCl 4 oz., $MgSO_4.7H_2O$ 2 oz., $Na_2SO_4.10H_2O$ 2 oz., H_3BO_3 1 oz. This soln. should have $p_H = 6.8$. The castings are then rinsed in cold and hot water, dried in sawdust, color buffed and are now ready for Cr plating. When wiped clean they are mounted on Cu racks and plated in the following Cr soln.: water 1 gal., CrO_3 48 oz., Fe chromate 1 oz., c. p. Na_2SO_4 0.5 oz. This bath is operated at 32° and a c. d. of 75 amp./sq. ft. of surface. A 3–5 min. plate is sufficient to insure lasting service. After being washed in cold and boiling water the castings are dried at 93° and color buffed. D. THUSSEN

The electrodeposition of chromium—practical difficulties and their obviation. J. W. CUTHBERTSON. *Chem. Trade J.* **87**, 371–2(1930); cf. *C. A.* **24**, 5640.—The prepn. of the work, the plating soln., hints on technic and the effect of base metal are reviewed. Electrolytic iron tanks with sides glass-lined and heated by gas burners from below are economical. The anodes should be Pb. The sulfate ratio of the vat is important. In bright chrome plating baths the ratio between CrO_3 and $Cr_2(SO_4)_3$ may be expressed in the form: $\frac{CrO_3 \text{ molarity}}{SO_4 \text{ normality}}$ = a factor, approx. 50. Motion of the article being plated appears to have little noticeable effect. W. H. BOYNTON

Researches on the electrodeposition of chromium. OSVALDO MACCHIA. *Chem. News* **141**, 1–7(1930); cf. *C. A.* **24**, 1582.—A bibliography and brief review of the various theories put forward to explain Cr deposition since Bartoli and Papasogli first mentioned it in 1883 are given. Most writers, it is pointed out, are unanimous in admitting the formation of a solid or colloidal film of oxide or hydroxide at the cathode. The aim of the present researches was to prove experimentally the existence of such a film at the cathode, and to expound better the phenomena which appear during the deposition of Cr. Results have been obtained (in the first part) which afford some proof of the variation of the thickness of the cathode film, and (in the second part) the relation existing between the quantity of sulfate ion present in the plating soln. and the thickness of the film. The exptl. conditions for the first part were 500 cc. soln. contg. 250 g./l. CrO_3 and 2.5 g./l. H_2SO_4; sheet Pb (contg. 6% Sb) circular anode, 2 mm. × 13 mm.; cathode, cylindrical Cu rod, 6 cm. long and 0.5 cm. diam. welded to Cu rod 2 mm. in diam. attached to an elec. motor for rotation. The expts. have confirmed the theory of the formation of a cathodic film. *E. g.*, with a c. d. of 12 amps./sq. cm. at 25° and a fixed cathode, the deposit was oxidized, but if the cathode was rotated sufficiently fast the deposit was bright: also, if the speed of rotation was less than 100 r. p. m. the deposit became less bright. Hence, the thickness of the film

around the cathode is not uniform but increases with the c. d. Further, at 25° with 5 amp./sq. cm. the deposit was bright, but at a c. d. of 12 amp./sq. cm. the deposit was oxidized. This, it is stated, makes it necessary to admit that in this last case the thickness of the cathodic film of H_2, or Cr oxide or hydroxide, solid or colloidal, is different and thicker, since the discharge of Cr ions is not obtained in such a way as to give bright deposits. Thus, there is a relationship between speed of rotation (and, therefore, thickness of film) and brightness. A table is given showing the type of deposit at various temps., c. ds. and speeds. Part II. A stationary cathode was used, temp. and c. d. were maintained const. and the sulfate content was varied by addns. of H_2SO_4. A table gives the relationships between c. d., g. H_2SO_4/l., ratio SO_4/CrO_3 and appearance of deposit. From the results obtained it is concluded that the thickness of the film is almost maintained const. when temp., bath compn. and c. d. are maintained const. When the sulfate ratio is greater than those given, the cathodic film is assumed to adsorb some of the sulfate ions, thus producing bright deposits. The formation of a dull deposit depends on the small thickness of the cathode film in relation to the greater quantity of sulfate ions which comes into contact with it during electrolysis; increasing c. d. increases the thickness of the film and, therefore, more sulfate ions are adsorbed, so that a bright deposit is thereby obtained. If the concn. of sulfate diminishes, then the deposit is duller, because of the insufficient quantity of sulfate ions coming into contact with the cathodic film, giving rise to the reactions by which a frosty deposit is formed: a decrease in c. d., and, therefore, in thickness of film, yields a bright deposit. The same hypothesis is used to explain the differences observed in the deposits with variation of temp. with const. CrO_3/H_2SO_4 ratio (a table of these results is also given). The brightness of Cr deposits depends on the thickness of the cathodic film, and on the quantity of sulfate ions present at a given temp. The thickness depends on c. d. and temp. since, with a rise in temp., it tends to become thinner. EDWARD B. SANIGAR

Basis for computations in electrolytic copper refining installations. HEINRICH WOHLWILL. *Metall u. Erz* **27**, 504–7(1930).—Comments upon an article under the same title by F. Vogel (*C. A.* **24**, 2675). H. STOERTZ

Electrolytic separation of the amino acids arginine and alanine. WALDERSEE HENDREY AND TREAT B. JOHNSON. *Biochem. Z.* **226**, 47–55(1930).—Good results are obtained with the aid of the 5 chamber electrodialysis app. and the control of the reaction of the medium by means of indicators. S. MORGULIS

Studies on the materials for the dry cell. I. II. SABURO MAKINO. *J. Soc. Chem. Ind.* (Japan) **33**, Suppl. binding 326(1930).—The e. m. f. and the capacity of the dry cell have no relation to the C content of graphite or C used. The difference of elec. resistance between the natural and artificial graphite on the market has little influence upon the e. m. f. and the capacity. The cell capacity has some definite relations to the grain size of MnO_2, to the relative quantity of the dioxide and graphite and to the rate of discharge. The electrode distance must be changed properly according to the rate of discharge. D. K. ALPERN

Study of light effects produced on electrodes during electrolysis. FRAYMANN. *Recherches inventions* **11**, 36–41(1930).—F. describes 3 types of luminous effects: (*a*) When an electrode is covered by a thin, insulating, insol. skin, the whole surface gives off a greenish yellow light of low intensity. This is especially noticeable in electrolytic rectifiers. Cathode and anode may give off light, depending on the nature of the electrolyte. F. describes the different effects obtained with Al as electrode in various electrolytes. (*b*) The second type is a continuous cathodic or anodic sparking obtained when heavy current densities are used through any kind of electrolyte. The sparking changes continually from place to place, and the color varies with the nature of the cathode. (*c*) The third type is a lilac light given on the surface of the cathode when heavy current passes through the electrodes. F. also describes the spectra of these lights and the app. used to obtain them. Numerous references are given. P. THOMASSET

The Wehnelt interrupter and crystal structure. SATYENDRA RAY. *Z. Elektrochem.* **36**, 425–7(1930).—A formula is developed. C. J. B.

Sphere electrodes under oil. J. L. MILLER. *Electrician* **105**, 254–5(1930).—Twenty-five impulses of 150,000 v. d. c. are impressed across 2 brass sphere electrodes immersed in transformer oil. With spheres 2.5 in. diam. having a 0.020 in. wall, indentations on both electrodes to a max. depth of 0.5 in. are obtained. The elec. energy content involved is less than 100 watt-sec. It appears that the distortion is due to rapid gas evolution as decompn. of the oil proceeds during the elec. discharge. The influence of elec. circuit parameters on the magnitude of the indentation is discussed. D. K. A.

Constant current obtained by electrolytic or thermoelectric methods. SATYENDRA

RAY. *Z. Elektrochem.* **36**, 425(1930).—A vertical tube (diam. not given) contg. $CuSO_4$ soln. (compn. not given) and equipped with Cu electrodes is connected to a galvanometer as for cond. measurements. Resistance up to 12,000 ohms was inserted in the circuit without modifying the potential between the electrodes. This potential is explained either electrochemically or electrothermally. C. J. B.

Space charges and spatial forces in insulation materials. P. BÖNING. *Z. tech. Physik* **11**, 373–6(1930).—From the general presence of colloidal particles in liquid insulating materials it is considered probable that free charges can occur in these fluids when exposed to an elec. field. Furthermore, because of the frictional resistance for the ions in the liquid (complementary ions and adsorbed boundary ions with attached colloidal particle (cf. *C. A.* **23**, 4147)) a hydrostatic pressure difference will occur at the electrodes relative to the surrounding liquid. This effect was studied, the present paper being a preliminary report. Of 2 parallel electrodes at 4 mm. distance in a glass vessel one was charged and the other one (measuring electrode) grounded. The latter had a —3 mm. hole in the center with attached glass manometer tube. Light transformer oil and gasoline were used as liquids, natural asphalt and colophonium being added to them as colloids. The potential used was 6000 v.; the temp. was 25°. For the pure oil only a slight difference in manometer height was observed; for gasoline none was observed on applying the potential. Addn. of the colloids previously dissolved in oil gave a pos. measuring electrode +12 mm. hydrostatic pressure (lasted 20 min.), for a neg. one +10 mm. (zero after 5 to 6 min.) with asphalt. For colophonium the resp. pressures were —3 mm. (after 20 min. —1/4 mm.) and +6 mm. (after 20 min. +5 mm.). Other solvents behaved in a similar way. Previously a study had been made of the behavior of colloidal charges on passing liquids through fibers (Diss., Braunschweig 1926); the relations found for the pos. asphalt and the neg. colophonium colloid are discussed in connection with the present effect. A few other observations on these liquids are given. On pouring an asphalt soln. in gasoline the mixing takes place very slowly; application of an elec. field causes rapid homogenization. In high-tension cables the proper field caused by the colloidal space charges in the cylindrical space between the 2 electrodes (insulating layer) will cause an enrichment of colloid (impregnation mass) outside the insulating paper layer. The simple equation for attraction of 2 electrodes does not hold when insulation with space charges is introduced between the 2. B. J. C. VAN DER HOEVEN

The measurement of high voltages, with special reference to the measurement of peak voltages. R. DAVIS, G. W. BOWDLER AND W. G. STANDRING. *J. Inst. Elec. Eng.* (London) **68**, 1222–30(1930).—Two methods of measuring peak voltage have been investigated. One method involves a condenser divider with the voltage on the low-voltage arm of the divider rectified. In the other the current through a condenser connected across the voltage to be measured is rectified, and the mean current so obtained is a measure of the peak voltage across the condenser. The accuracy of the methods is considered theoretically for different wave forms; results by the 2 methods are compared and the agreement is found to be about 2 parts in 1000 for peak loads up to 10^6 where suitable conditions exist and all necessary precautions are taken. W. H. BOYNTON

Electrical porcelain. I. J. K. GILLETT. *Electrician* **105**, 434–6(1930).—The mineralogical microscope makes it possible to det. the quality of the finished product and to predict its performance. The manuf. of porcelain insulators is outlined and a practical comparison of 2 com. bodies made. Glaze and porosity are shown to affect porcelain performance. W. H. BOYNTON

Recent developments in (incandescent) lamp manufacturing. J. A. JONES AND E. I. MORWICK. *Elec. News Eng.* **39**, 39–48(1930).—9 illus. C. G. F.

A method for studying the drying of paste in pocket lamp dry cells. HANS GRIMM. *Z. Elektrochem.* **36**, 427–8(1930).—The jacket contg. the C electrode and the depolarizer is stained by pressing it on a filter paper dusted with acetylene lamp-black; then it is pressed on a clean piece of filter paper. The impression which is produced on the clean paper is fixed by spraying with alc. shellac; it may then be planimetered to measure the light and dark areas to indicate the extent of drying. C. J. B.

Electricity in vessels in brewing (JAKOB) 16. Electricity in fermentation and storage vats (HALLERMANN) 16. Manufacture of chromic anhydride for electroplating (LAFIN, GOLTZ) 18. Alloys for electrical contacts (U. S. pat. 1,779,602) 9. Electric apparatus for dehydrating petroleum oils (U. S. pat. 1,779,695) 22. Electrophoretic deposition of rubber, etc. (Brit. pat. 331,563) 30. Openwork metal designs (Brit. pat. 331,856) 5. Electrodeposition of rubber (U. S. pat. 1,778, 841) 30.

Dry cell electric battery. CHARLES A. GILLINGHAM (to National Carbon Co.). U. S. 1,779,767, Oct. 28. Structural features.

Dry cell electric battery. J. M. HENDERSON (to Burgess Battery Co.). Brit. 331,467, Nov. 2, 1928. The dolly of the battery is coated with a compn. consisting of a fibrous material such as wood pulp, hair, asbestos or cotton linters mixed with a flake material such as graphite, mica or Al bronze and a colloid such as starch.

Forming dollies of electric dry cell batteries. H. A. BUMKE GES. and AUTOM SPEZIAL-MASCHINEN GES. Brit. 332,101, July 26, 1929. Mech. features. Brit. 332,103 (H. A. BUMKE GES.) also relates to manuf. of dry cell batteries with an electrode consisting of a carbon rod surrounded by depolarizer and provided with a protective coating such as collodion permeable to the electrolyte and describes app. for coating the electrodes.

Sheet zinc cups for electric batteries. A. GASSAN and P. RUCK. Brit. 331,650, May 22, 1929. Longitudinal joints of sheet Zn cups are formed by die-casting Zn or a more easily fusible metal electrically equiv. or inactive to Zn. Various structural details are described.

Electric battery electrodes. A. KUNZE. Brit. 332,155, Oct. 24, 1929. To secure a MnO_2 depolarizer contg. exciting salts to a C electrode, a small quantity of a resin such as coumarone resin is mixed with the depolarizer and the assembly of C rod and depolarizer is heated sufficiently to melt the resin without decompg. the depolarizer.

Electrodes for sea batteries for firing explosive mines. J. K. M. HARRISON. Brit. 332,233, March 9, 1930. Structural features.

Sea batteries for firing submarine mines. J. K. M. HARRISON. Brit. 332,265, March 9, 1929. The low voltage from a sea battery is converted to high voltage for firing a spark-gap detonator. Various details of elec. app. are described.

Porous metal articles such as storage-battery electrodes. I. G. FARBENIND. A.-G. Brit. 332,052, July 8, 1929. Metal powders such as Fe, Ni, Co or their mixts. are sintered at a relatively low temp. (suitably 500–700°) and then further sintered at a higher temp. (suitably 800–1200°) in a reducing or inert atm. or *in vacuo*. Other finely divided metals such as Cu or reducible oxides, hydrates, carbonates, etc., may be added.

Storage battery. WALTER E. HOLLAND (to Philadelphia Storage Battery Co.). U. S. 1,781, 640, Nov. 11.

Storage batteries. I. G. FARBENIND. A.-G. Brit. 331,540, Jan. 4, 1929. Electrodes comprise supports of porous iron, Ni, Co, Cd or ferroso-ferric oxide, the pores of which are filled with active material which may be introduced into the porous metal support by impregnating the latter with solns. of salts such as nitrates and heating. The walls of the pores in the support material may be preliminarily coated with a resistant metal such as Ni or Co before introduction of the active material, to prevent the electrolyte from attacking the support. Various details of manuf. are described. Cf. *C. A.* **24**, 3183.

Alkaline storage battery. JOHN F. MONNOT. U. S. 1,780,935, Nov. 11. Metal tubes of circular cross-section, for use in the pos. plates of alk. storage batteries, have a filling of alternate layers of Ni hydroxide and pieces of perforated Ni foil of larger area than the cross-section of the tube.

Hydrometer for testing electrolyte of storage batteries. LAWRENCE J. PEARSON (to Philadelphia Storage Battery Co.). U. S. 1,781,597, Nov. 11. Structural features.

Storage-battery separators formed of slitted material such as celluloid or ebonite. PAUL PAUTOU (to Soc. anon. des accumulateurs monoplaque). U. S. 1,779,286, Oct. 21. Structural features, relating to separators with slits having irregular walls to prevent their closure from coming together of the walls.

Electrodeposition of metals on wood, etc. I. AINSTEIN. Brit. 331,863, April 9, 1929. A surface of wood or other material is prepd. to receive an electrolytic deposit of metal by atomizing on it an alloy of easily fusible metals such as Pb, Sb, Bi, Sn and Zn, followed by a preliminary electroplating in a bath at a temp. of 10–30°, the main plating operation being carried out in a hot bath. The article may be preliminarily dipped in a sol. silicate soln. and its surface sanded and dried, and after the first treatment with metal may be given an intermediate treatment with Cu, bronze or brass.

Electrodeposition of metals of the platinum group. CHRISTIAN W. KEITEL (to Baker & Co.). U. S. 1,779,436, Oct. 28. In the deposition of Pt, Pd or Rh, metal deposited from the soln. is renewed by adding an amino nitrite of the metal while keeping the soln. ammoniacal.

Electrodeposition of platinum group metals. HERBERT E. ZSCHIEGNER (to Baker & Co.). U. S. 1,779,457, Oct. 28. An electrolyte for deposition of Pt, Pd or Rh com-

prises a heat-treated aq. soln. of a chloride of the metal and an excess of $NaNO_3$ contg. also an excess of NH_3.

Electrodeposition of zinc and other metals. U. C. TAINTON. Brit. 332,244, April 17, 1929. Mist or spray formation from $ZnSO_4$ solns. or other electrolytes is supressed by adding a small proportion of silicic acid and an org. compd. such as cresylic acid, stabilized rubber latex or saponin capable of forming a froth over the surface.

Chromium plating. WM. M. PHILLIPS (to General Motors Research Corp.). U. S. 1,780,535, Nov. 4. A bath contg. chromic acid as the principal substance in soln. and substantially free from other constituents tending to attack iron during the Cr deposition is used with an anode formed mainly of iron.

Chromium plating ferrous metals. VINCENT M. VERTUCCI. U. S. 1,780,213, Nov. 4. Metal such as iron or steel is heated to dull redness, cooled and immediately cleaned (suitably by HCl, NaOH and electrolysis in dil. H_2SO_4 soln.) to prepare it for Cr plating.

Two-toned finish on metal surfaces. MARVIN J. UDY. U. S. 1,780,212, Nov. 4. A portion of a surface is coated with a substance such as re-etching ink which retards the action of electrodeposition on such portion but is gradually removed during such action; the coated surface is immersed in an electroplating soln. such as one contg. chromic acid and a sulfate having an etching action on the metal during the period of retarded deposition and both the coated and uncoated portions are subjected to electroplating action which is continued until after the coating has become removed and both the coated and uncoated portions are electroplated.

Impregnating carbon electrodes for use in electrolysis of alkaline chlorides. OTTO A. LAUBI (to Bozel Maletra (Soc. industrielle de produits chimiques)). U. S. 1,779,242, Oct. 21. A partially halogenized hydrocarbon material such as a chlorinated paraffin is used as impregnating agent, in order to improve the durability of the electrodes.

Refining crude antimony electrolytically. HEINRICH ROSCHER (to Norddeutsche Affinerie). U. S. 1,780,944, Nov. 11. An electrolyte is prepd. with SbF_3 contg. about 100 g. free H_2SO_4 per l. and about 20 g. free HF per l., and there is introduced into this an Sb anode sol. in the electrolyte and contg. impurities such as Pb insol. in the electrolyte. The electrolyte is of such character as to prevent the anode from becoming passive, and Sb is deposited substantially without deposition of Pb.

Apparatus for measuring conductivity of electrolytes. A. SCHWARZ and B. LANGE. Brit. 332,240, April 15, 1929. An app. is described suitable for direct connection to a. c. lines and which may have a rectifier of the Cu oxide type.

Electrolytes for switches passing high currents. M. PAUL and P. WANGEMANN. Brit. 331,852, April 8, 1929. Currents such as those of about 5000 kilowatts are broken without production of an arc by the use of a good cond. acid or base of a cond. of at least 0.1 reciprocal ohms (preferably a 28% KOH soln.). Various details of construction are described.

Acetylene and hydrogen from methane by electric arc treatment. I. G. FARBENIND. A.-G. Brit. 332,057, July 12, 1929. In producing C_2H_2 and H from CH_4 or gases contg. the latter, gases remaining after whole or partial sepn. of the C_2H_2 are divided into 2 parts, one of which is mixed with fresh gases and the other further treated in a second arc or arc system. The process is preferably effected under slightly reduced pressure and various details and modifications of procedure are described.

Porous sheets for use in electrolytic cells, etc. I. G. FARBENIND. A.-G. Brit. 331,197, Jan. 24, 1929. A porous substance such as coarse raw kieselguhr is incorporated with polymerization products of butadiene and various other substances may be added such as S, ZnO, diphenylguanidine, naphthylamine and reënforcing fabric or metal network, and sheets of the material may be vulcanized.

Porous sheets for electrolytic cells, etc. I. G. FARBENIND. A.-G. Brit. 331,227, Jan. 24, 1929. A polymerization product of butadiene is mixed with a substance which yields a gas on heating or which can be dissolved out such as NaCl or Na_2CO_3 or $(NH_4)_2CO_3$ and porosity is subsequently produced by heating or dissolving out the added substances. Fillers, vulcanizing ingredients, etc., also may be added and the material may be vulcanized.

Electrolytic cell suitable for rectifying alternating currents. WALTER E. HOLLAND and LAWRENCE J. PEARSON (to Philadelphia Storage Battery Co.). U. S. 1,781,641, Nov. 11.

Alternating-current rectifier. HENRI G. ANDRE. U. S. 1,780,056, Oct. 28. A film-forming cathode such as ferro-Ni is used with a finely divided anode material such as Ag and a slightly ionizable liquid such as H_2SO_4 or H_3PO_4 from which the oxidation product carried by the cathode is derived. Various structural details are described. U. S. 1,780,057 describes the formation of a rectifier by placing one electrode about the

other, *e. g.*, a Ag wire helix around a rod of Ni alloy, immersing in a soln. such as H_2SO_4 to produce an oxidation product on one of the electrodes, passing elec. current through the rectifier to form a colloid, and removing excess soln.

Electric current rectifier of the mercury-vapor type. JOHANNES KUBLER and ERNST KOBEL. U. S. 1,781,286, Nov. 11. Structural features.

Mercury-vapor rectifier. LLOYD SMEDE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,781,305, Nov. 11. Anodes are formed of a non-noble metal such as case-hardened iron which is not readily attacked by Hg vapor and which contains inclusions of materials of relatively great electron emissivity, as compared to iron, at the working temps., in the interior of the anodes, and carbides of the inclusions at the surface.

Ignition device for mercury-arc rectifiers. JULIUS JONAS (to Akt.-Ges. Brown, Boveri and Cie.). U. S. 1,781,330, Nov. 11. Structural features.

Cooling system for mercury-vapor high-vacuum pumps of rectifiers, etc. AKT.-GES. BROWN, BOVERI ET CIE. Brit. 331,446, Oct. 5, 1928.

Electrical condenser. ELLERY T. HOCH (to Bell Telephone Laboratories, Inc.). U. S. 1,780,917, Nov. 11. Layers of metal foil and paper are enclosed in a container with an impregnating and filling mixt. contg. petrolatum and "mineral beeswax" (a described petroleum wax resembling beeswax.)

Electrical condenser. SAMUEL RUBEN (to Ruben Patents Co.). U. S 1,781,033, Nov. 11. A dielectric for elec. condensers comprises a mixt. of finely divided cryst. TiO_2 and a viscous org. binder such as petroleum jelly.

Electric resistance annealing furnace. HIRSCH, KUPFER- UND MESSINGWERKE A.-G. Brit. 331,793, Dec. 15, 1928. Structural features.

Electric resistance furnace for annealing metals in a non-oxidizing atmosphere. C. F. KENWORTHY. Brit. 332,436, Jan. 14, 1929. Various structural details are described.

Electric tube resistance furnace suitable for heating metal billets. R. M. CATTERSON-SMITH. Brit. 332,015, June 7, 1929. Structural features. Brit. 332,016 also relates to an elec. furnace for heating billets and to mechanisms for conveying the billets.

Electric induction furnace. N. R. DAVIS and ASSOCIATED ELECTRICAL INDUSTRIES, LTD. Brit. 331,324, May 8, 1929. Structural features.

Electric induction furnace. N. R. DAVIS, M. J. MARCHBANKS, J. H. LUDLOW and ASSOCIATED ELECTRICAL INDUSTRIES, LTD. Brit. 332,325, May 8, 1929. Structural features.

Reductions in electric induction furnaces. W. B. HAMILTON and T. A. EVANS. Brit. 331,892, Feb. 5, 1929. Reductions such as those of chromite ore with ferro-Si are started by incorporating an elec. conductor or primer (such as Fe or Fe-Cr alloy) in the mixt. If Ni-Cr alloy is being prepd., Ni-Cr conductors are used. Various details of procedure are described.

Stirring and poking apparatus for electric furnaces. PAUL L. J. MIGUET (to Soc. électrométallurgique de Montricher). U. S. 1,778,809, Oct. 21. Structural features.

Resistance unit for electric heating apparatus. DAVID G. PETRIE (to Young, Osmond & Young Ltd.). U. S. 1,778,811, Oct. 21.

Electric heating elements. KOJYU NOGUCHI (to Mitsubishi Zosen Kabushiki Kaisha). U. S. 1,779,822, Oct. 28. In forming elec. heating elements having a compact filling composed mainly of alumina, powd. Al is mixed with powd. lime in the proportions of about 2 to 1, the space between an elec. heating element such as a wire and its metallic sheath is filled with this mixt., and water is added to effect conversion of the Al into Al_2O_3.

Apparatus for electrical precipitation of suspended particles from gases. H. V. WELCH and LODGE-COTTRELL, LTD. Brit. 331,699, July 11, 1929. Structural features.

Electrode vessel suitable for hydrogen-ion determinations. STANLEY L. HANDFORTH (to E. I. du Pont de Nemours & Co.). U. S. 1,779,232, Oct. 21. A reference cell and a NaCl cell are electrolytically connected by porous plugs. Various details of construction are described.

Device for detecting oxygen in hydrogen. GAYLORD W. PENNEY (to Westinghouse Elec. & Mfg. Co.). U. S. 1,778,834, Oct. 21. In app. such as H-cooled elec. app., an elec. fan is operated in a chamber contg. the H and infiltration of O into this chamber serves to increase the pressure of the gas and vary the quantity of power required to operate the fan. Various details of app. are described.

Electric hygrometer. W. LUBACH and E. GIESER (trading as Editenfra Editio Teuto-Franka). Brit. 332,135, Oct. 1, 1929. Structural features.

Gas-producer valve-control system, etc. C. MIEDBRODT. Brit. 332,097, Aug. 12, 1929. Elec. app. is described for operating a warning signal and closing all valves for

interrupting the operation of a producer when any of the valves fails to be correctly actuated in its proper order.

5—PHOTOGRAPHY

C. E. K. MEES

New type of pure light photograph. G. KÖGEL. *Phot. Korr.* **66**, 29(1930).—K. describes a new and theoretically interesting process in which the sensitive material is a colorless or nearly colorless compd., such as that obtained by fusing together ϕ-nitrophenylpropiolic acid and thiosinamine. This changes spontaneously in the dark to a dye, the change, however, being permanently prevented by an exposure to light. A direct positive picture, permanent in light, is thus possible, and without the need for development or fixing. E. R. BULLOCK

Photography on copper. C. J. SMITHELLS. *Nature* **126**, 133(1930).—A polished Cu or brass surface, after cleaning, is dipped into 10% $CuCl_2$ soln. for 10 sec. The thin white CuCl film is washed in H_2O, rinsed in alc., and air dried. Contact prints from ordinary negatives may be made by exposure of 1 min. to an arc lamp. The image is fixed by washing in dil. "hypo" or salt soln. Also in *Brit. J. Phot.* **77**, 461 (1930). ARTHUR FLEISCHER

Optical photographic properties of certain groups of sensitizing and desensitizing dyes of the cyanine and related series. O. BLOCH AND FRANCES M. HAMER. *Phot. J.* **70**, 374(1930).—The pseudocyanines derived from a no. of representative heterocyclic bases were compared optically and photographically with the corresponding styryls and anils (obtained by condensing the appropriate quaternary salts with *p*-dimethylaminobenzaldehyde and *p*-nitrosodimethylaniline, resp., although some of the cyanines show double-banded absorption, the styryls and the anils possess, as a rule, broad single bands, those of the anils being invariably nearer the red end of the spectrum than those of the corresponding styryls, while most of the cyanines have a band nearer the blue than the styryls. With some cyanines a change in the positions of the absorption bands according to the concns. of the solns. tested was observed. In related series, increase in mol. wt. produced, in most cases, a shift in the absorption bands toward the red, while in both the styryl and cyanine series there was no deviation from the general rule that the sensitizing band is situated nearer the red than the absorption band, the shift varying from 25 to 80 mμ. Since some sensitizers are also desensitizers, the anils (which usually desensitize powerfully) were tested over long exposures for possible sensitizing action, but none was found. Two cinnamylidene derivs. (obtained from *p*-dimethylaminocinnamaldehyde) were tested and one was a weak sensitizer, less powerful than the corresponding styryl, while the other had practically no photographic action. Both Me groups in 2, 4-dimethylquinoline may be made to react so as to give a distyryl and a dianil deriv. The former was of no value as a sensitizer. L. G. S. BROOKER

Desensitizing properties of basic scarlet N. FRANCES M. HAMER. *Phot. J.* **70**, 436(1930).—Basic scarlet N is shown to be a mixt. of a safranine with a chrysoidine, the 2 components having been sepd. When used in 1:5000 soln., its desensitizing action is at least equal to that of a safranine soln. of the same dilution, but, unlike the latter, it causes a slight destruction of the latent image. Since, moreover, the dye stains almost as much as safranine, it is not superior to the latter in practice. When used in a concn. of 1:1000 or 1:5000, the characteristic inhibiting influence of the chrysoidine on the rate of development becomes very apparent. L. G. S. BROOKER

Photographic significance of the reduction–oxidation cystine–cysteine system and analogous disulfide–sulfhydryl systems. A. STEIGMANN. *Phot. Korr.* **66**, 88(1930).—S. shows that (under certain conditions) cystine, acting presumably as a reducible S compd., is able to increase very considerably the sensitizing action of another S compd.; it thus appears to activate the H rather than the S of the latter. E. R. BULLOCK

Microscopic and ultramicroscopic studies of transverse sections of photographic layers. K. SCHAUM AND O. KLEIN. *Z. wiss. Phot.* **28**, 43–71(1930).—The technic of making the sections is fully described. The authors studied exposed and developed Ag grains along with unexposed AgBr, the depth action of aminophenol developer, intensified and reduced densities, resolving power, reversal phenomena and colloid colors in photographic layers in a series of excellent microscopic studies. A. P. H. T.

Halogen values of silver iodide emulsions: Their determination and photographic significance. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 111(1930).—

After HNO_3 treatment only I ions could be found in the filtrate of the AgI emulsions investigated. The emulsions were prepd. with excess of KI. The amt. of sol. iodide is detd. by the kind of emulsion and by the grain size, and differs considerably from what was previously found with AgBr emulsions. This shows that the photographic emulsion presents a very complicated picture and only detn. of the photographic properties together with chem. analyses can give fuller knowledge. A. P. H. TRIVELLI

Nomenclature of silver and halogen values in photographic layers. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 118(1930).—The authors criticize Weigert and Lühr's expression of "Ursilber" for the values of free Ag detd. in photographic emulsions. A. P. H. TRIVELLI

Stationary conditions in photographic materials. LÜPPO-CRAMER. *Phot. Ind.* **28**, 777(1930).—The author reviews previous work where increased exposure of photographic materials has yielded no increase or decrease in developed images. This stationary effect has been noticed in HgI_2-gelatin emulsion, in AgI-gelatin emulsion, and in AgBr-gelatin emulsion desensitized with phenosafranine and KBr. In this last case, the stationary condition may be the result of a fortuitous balancing of the primary exposure process with reversal. Expts. are given showing how reversal tendency depends on conditions of exposure and relative amts. of phenosafranine and bromide. C. E. MEULENDYKE

Nucleus denudation by alkalies and alkaline salts in the case of chromic acid-treated exposed silver halide plates. H. H. SCHMIDT. *Phot. Korr.* **66**, 68(1930).—Some large values for the nucleus denuding action of alkalies are recorded. Conclusion: The difference between the sensitivity and the development centers is not fundamental, but at most one of degree. E. R. BULLOCK

Avoidance of halation and solarization. K. HELLER. *Camera (Luzern)* **9**, 33 (1930).—The exposed plate is first given a protracted development in an oxidized partially exhausted glycine developer until the highlights appear. It is then given 35 to 45 seconds development in a warm (28° to 30°) caustic soda-pyrocatechol developer to bring out the shadows. H. claims that by this method plates having a brightness range of 1:1500 may be easily developed to give normal negatives. M. W. S.

Solarization. I. Influence of bromine ions on solarization. H. ARENS. *Z. wiss. Phot.* **28**, 91(1930).—Bromide increases solarization only if it is present during the exposure. Removal of the sol. bromide by $AgNO_3$ and removal of $AgNO_3$ by NaCl prevent solarization in a great no. of com. plates. Peptized AgBr shows a diminution of solarization after such treatment. Addn. of KBr immediately reinstitutes solarization. The resolving power in the solarization region of plates treated with $NaNO_3$ can be destroyed by KBr. **II. Dependence of solarization on the mode of preparation of photographic emulsions.** *Ibid* 98.—AgBr peptized in $AgNO_3$ solarizes less than AgBr peptized in KBr. Greater excess of KBr diminishes solarization. No relation could be found between solarization and grain size. Peptizing with NH_3 increases the solarization considerably. A. P. H. T.

Metallic silver in undeveloped photographic layers. I. F. WEIGERT AND F. LÜHR. *Z. wiss. Phot.* **27**, 312–37(1930).—The high "Ag values" of undeveloped photographic layers were regarded by the authors as metallic Ag. This was criticized by others. Therefore, a new method of fixing by $Na_2S_2O_3.5H_2O$ was worked out which practically removed all Ag otherwise left in the photographic layer. The "Ag values" were redetd. and gave slightly lower values than those previously obtained. Treatment with persulfate showed that the Ag values obtained were due to metallic Ag and not to Ag_2S. The relation between this analytically determinable amt. of free metallic Ag and the photographic properties are discussed. A. P. H. TRIVELLI

Gravimetric determination of excess of silver in photographic gels. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **28**, 30–4(1930).—This is a reply to the criticism of Arens and Jessien (*C. A.* **24**, 5649). The Ag values of photographic emulsions by the gravimetric method show that the excess of Ag (metallic Ag + organic Ag compds.) was originally present in the emulsion and is not formed during the action of HNO_3 by reduction of Ag halide. A. P. H. TRIVELLI

Chemical nature and the origin of relatively high silver values in silver chloride and a new method of determination and separation of the silver values by sedimentation. H. H. SCHMIDT AND F. PRETSCHNER. *Z. wiss. Phot.* **38**, 35–40(1930).—The Ag values are detd. after pptn. of the Ag halide by the addn. of alcohol or $K_2C_2O_4.H_2O$. The clear liquid above the ppt. is suitable for Ag detns. A very quick sedimentation because of liquefaction of the gelatin may be produced by addn. of sulfosalicylic acid. That part of the Ag which is sol. in Na_2SO_3 originates in the action of $AgNO_3$ on a

gelatin compd. and contains no nitrate group. The action of KCl on this Ag compd. is less pronounced than that of KBr and KI and is the source of fog in paper emulsions on longer development. Removal of this Ag compd. by chromic acid or by centrifuging removes the fog. Diminution of the Ag values from Cl to I is probably caused by the decreasing formation of organic Ag compds. It is very probable that the compd. which is formed by the action of $AgNO_3$ on gelatin is identical with the Ag value which is sol. in Na_2SO_3. A. P. H. TRIVELLI

Photolyses of some diazo compounds. W. SCHRÖTER. *Z. wiss. Phot.* **28**, 1–29 (1930).—The bleach and N detn. methods were employed on the diazo compd. (I) of 2-amino-1-naphthol-4-sulfonic acid and the diazo compd. (II) of *p*-aminodiphenylamine. Within wide limits the light action is independent of intensity and wave length, and of concn. and temp. of the soln. The quantum effect, γ, with wave length λ = 436mμ is $\gamma = 0.40 \pm 0.06$ for I, and $\gamma = 0.52 \pm 0.05$ for II detd. by the bleach method. The N method gave, for I, $\phi = 0.35 \pm 0.03$, and for II, $\phi = 0.20 \pm 0.02$. X-ray irradiation did not liberate N_2 in the solid substance I in spite of the fact that a noticeable change had taken place. The influence of acidity and the behavior of solvents such as EtOH and MeOH were investigated. The quantum effect on diazobenzenesulfonic acid and its Na salt was detd. by the N method, and was $\phi = 0.07$ to 0.1. A tentative hypothesis in explanation of the results is proposed. A. P. H. T.

The reversal of silver gelatino-bromide papers. L. LOBEL AND M. DUBOIS. *Chimie & industrie* Special No., 385–6(March, 1930).—Positives cannot be obtained directly on gelatino-bromide paper by the process used for the reversal of "Pathé Baby" films (complete darkening of the residual AgBr) because with most papers pure whites cannot be obtained after reversal. The treatment used for autochrome plates (*Agenda Lumière* 1929, p. 280) was found to give excellent results, and required only normal exposure (instead of over-exposure as in the other process), but the time required for developing is considerably longer to dissolve completely the excess of AgBr which is not required for the formation of the reversed image. A.P.-C.

The fate of the iodide in the development of bromo-iodide emulsions. M. L. DUNDON AND A. BALLARD. *Brit. J. Phot.* **77**, 90–1(1930).—A description is given of the probable course of the development of bromo-iodide emulsions whereby the sol. iodide liberated by development is redeposited on undeveloped AgBr grains. It was found that with partial exposure most of the iodide remains in the undeveloped portion of the emulsion but with full exposure it can be leached out into the developer. The small quantity of iodide which accumulates in a used developer is a very important factor in its decreased fogging action. M. L. DUNDON

The action of light on silver bromide. A. C. CHATTERJI AND P. S. MACMAHON. *J. Indian Chem. Soc.* **7**, 443–9(1930).—The absorption of O by AgCl has been studied to no small extent. Little work, however, has been carried on in the study of the absorption of O by AgBr. The authors found that, when pure, dry AgBr was sealed in a tube with O, and exposed to the tropical sunlight for long periods of time, absorption takes place in all cases to almost the same degree as that with AgCl. The amt. of absorption is dependent upon the exposed surface rather than the vol. of the AgBr. The darkened product contains O, and its formation is hastened by the presence of oxidizing agents. When dispersed Ag is formed by striking an arc in air, O and N, it is contaminated with oxide and nitrate. The dispersed Ag produced in air is capable of further oxidation when exposed to dry O. The photobromides formed are not due to the photochem. synthesis of an oxy. compd., but are due partly at least, to the direct absorption of O by the disperse Ag produced in the photochem. decompn. of the AgBr, resulting in a partial oxidation of the disperse Ag formed. W. VANSELOW

Deterioration of sulfite-hydroquinone solutions and the mode of activity of cold solutions. J. PINNOW. *Z. wiss. Phot.* **27**, 344–60(1930).—By careful oxidation with permanganate in H_2SO_4 soln. in the cold., α- and β-hydroquinonedisulfonic acid gave compds. which liberate, on boiling, oxalic acid and large amts. of sulfonic acid. A similar oxidation by air could explain the formation of the "complex compound" observed by Schilom and Fedotoff, which formed in solns. having no more developing power. The sulfite soln. in the developer is better protected against oxidation by a mixt. of α- and β-hydroquinonedisulfonate than by hydroquinone. A. P. H. TRIVELLI

Destruction and intensification of the image during bright light development. LÜPPO-CRAMER. *Z. wiss. Phot.* **27**, 305–11(1930).—Fog on exposed plates bathed in desensitizers can be prevented by exposing the plates wet to red light. With increasing red light exposure the latent image is destroyed more in the lower than in the higher density region, resulting in an increased contrast of the reduced image. It was found

that in desensitized plates the latent image increased with green light exposure. A. P. H. TRIVELLI

Mineralogical contributions to the theory of the latent image. R. E. LIESEGANG. *Phot. Ind.* **28**, 805(1930).—L. calls attention to 2 recent publications in the field of radioactivity on the formation of colloidal Na in bluish rock salt and on the formation of colored colloidal Au in fusions of alk. halides. Analogy to the latent image problem of photographic exposure is suggested. Regarding the radioactivity of K in fogging photographic materials, K. Przibram has calcd. that an exposure of 20,000 years is necessary to produce a bluish color in rock salt by K radiation. C. E. M.

Optical investigations on the formation of the latent photographic image. M. SAVOSTIANOVA. *Nature* **126**, 399(1930).—When rock salt is exposed to short wave length radiation, it becomes colored; this color can be removed by heat or by exposure to light of a wave length absorbed by the new absorption band thus produced. A similar effect is obtained with AgBr. The new absorption band has a max. at 610 mμ, and continues uniformly as far as 2000 mμ into the infra-red. With rock salt, simultaneous illumination and heating produce colloidal clumps of Na atoms; AgBr exposed to active and decolorizing radiations becomes brown, probably because of the formation of colloidal Ag. E. W. H. S.

Colloido-chemical foundation of toning by direct development. G. SCHWARZ. *Phot. Korr.* **66**, 59(1930).—A general review is given of the colloido-chem. phenomena in toning by direct development, from which it is shown that the resulting color tones are primarily dependent upon the ratio of the velocity of soln. of the Ag halide to the velocity of its chem. reduction. S. discusses this fact (which has long been taken into account in practice) from a uniform physicochem. point of view. E. R. B.

Two-bath development for the elimination of abrasion marks. RAFAEL GARRIGA. *Chimie & industrie* **Special No.** 387(March, 1930).—Abrasion marks can be prevented by adding 1–5 g. $Na_2S_2O_3$ per l. of developing bath; but development is thereby retarded and the image is weak and grayish. This is overcome by starting development in a bath consisting of: normal hydroquinone developing soln. 100, H_2O 100, 10% $Na_2S_2O_3$ soln. 20; when the contours of the image show up, quickly wash with water and finish development in a normal undiluted bath. A. PAPINEAU-COUTURE

Concentration speck theory and crystal structure strain. A. P. H. TRIVELLI. *Z. wiss. Phot.* **28**, 41–2(1930).—T. claims priority for laying the foundation of the crystal lattice strain theory of light sensitivity. A. P. H. TRIVELLI

Concentration speck theory and centripetal theory of light action. A. STEIGMANN. *Z. wiss. Phot.* **28**, 167(1930).—A controversy with Trivelli (preceding abstr.) about priority for the concn. speck theory of the latent image and the tension theory of light sensitivity. A. P. H. TRIVELLI

Some properties of fixing baths. J. I. CRABTREE AND H. A. HARTT. *Trans. Soc. Motion Picture Eng.* **13**, 364(1929); *Brit. J. Phot.* **76**, 743–5, 758–61, 777–8(1929); **77**, 4–6, 19–22 (1930).—The hardening characteristics of acid-alum fixing baths are not related to the alum concn. alone, but are also affected by the addn. of acetic acid and sulfite. It is possible to compound fixing baths having any desired properties by referring to a series of curves prepd. from exptl. data. $NaC_2H_3O_2$ may be used to replace the sulfite in a fixing bath, but it is only $^1/_5$ as efficient as a sulfurization inhibitor. Under certain conditions where the efficiency of the fixing bath is detd. by the quantity of developer which may be added before Al sulfite is pptd. it has been shown that the addn. of acid at intervals during exhaustion is advantageous. Practical recommendations are made relative to the use of plain acid and of acid hardening fixing baths. J. I. CRABTREE

Actinic and color temperature of magnesium ribbon burning in air and of magnesium flashlight. J. M. EDER. *Z. wiss. Phot.* **27**, 337–43(1930).—The actinic value of 1 mg. Mg, burning in air, was redetd. and found to be 413 m. c. s. in relation to AgBr gelatin. Flashlight of Mg powder and nitrates is lower (200–300 m. c. s.). Burning Mg gives a double value in pure O. The color temp. of Mg burning in air is higher than that with $Th(NO_3)_4$. The color temp. of Mg burning in pure O is 4000°K. The color temp. of Mg flashlight with $Th(NO_3)_4$ is 3000–3100°K. A. P. H. TRIVELLI

Color photography. SOCIÉTÉ FRANÇAISE DE CINÉMATOGRAPHIE ET DE PHOTOGRAPHIE FILMS EN COULEURS KELLER-DORIAN, A. AVERAN and I. KITROSER. Brit. 331,971, Oct. 23, 1928. Optical features.

Optical system for color photography. HAROLD N. COX (to Cox Multi-Color Photo Co.). U. S. 1,781,496, Nov. 11.

Forming and projecting color photographs. M. B. DuPont. Brit. 331,200, Feb. 14, 1929. Optical features.

Photographic films. I. G. Farbenind. A.-G. Brit. 331,042, May 9, 1929. The sensitive surface at the end of a roll-film is colored as described in Brit. 308,693 (*C. A.* **24**, 305). A tanning agent may be used further to stabilize the coloring matter and a wetting medium such as Na phenylacetate or saponin can be used to facilitate uniform coloration.

Photographic reversal films. Erwin Mankenberg (to Agfa Ansco Corp.). U. S. 1,780,025, Oct. 28. The film is first subjected to an under-development, the Ag image is dissolved, the remaining Ag salt image is developed after a second exposure, followed by equalization of the excessive d. of the reversed image due to the first under-development by means of a solvent for Ag such as a bath prepd. from I, KI, thiocarbamide and water which has a uniform and even reducing action.

Cinematograph picture films. M. G. M G. Bizot. Brit. 332,195, Oct. 11, 1928. In developing and toning films sensitized with dichromated gelatin, unexposed dichromate is removed by washing with cold water, the unexposed gelatin is swelled by immersion in a bath of cold water contg. NaOCl followed by treatment with hot water and the remaining gelatin is dye-toned. The hot water may contain a trace of methylene blue to facilitate development and the same dye may be used for the dye-toning.

Photographic diazotypes. Kalle & Co. A.-G. Brit. 331,459, Oct. 19, 1928. Aromatic hydroxyl compds. contg. one or more guanidine groups, and in which the *o*- or *p*-position to the hydroxyl is non-substituted, are used as azo components in the diazotype process. Several examples are given.

Apparatus for developing photographic prints such as diazotypes with ammonia, etc. F. C. Fuke and Ozalid Co., Ltd. Brit. 331,823, April 5, 1929. Structural features.

Openwork metal designs. F. W. Miller. Brit. 331,856, April 9, 1929. A sensitized plate which may be coated with dextrin, glucose or gum arabic sensitized with a dichromate is exposed under a transparency of the design, metal or other cond. material is dusted on and adheres to the unexposed parts, a layer of collodion is coated on the design, the original coating is washed off (leaving the design of cond. material on the collodion) and metal is then electrolytically deposited on the design (which can then be stripped off and transferred to wood or other material for ornamentation).

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Correction to the work of Ipat'ev and Muromzev: Precipitation of crystalline hydroxides of aluminum and chromium from solutions of their salts at high temperature and pressure. V. Ipat'ev. *Ber.* **63B**, 2365(1930); cf. *C. A.* **22**, 1742.—The cryst. ppt. of the compn. $Al_2O_3 \cdot H_2O$ (previously considered identical with the mineral diaspore) gives an x-ray diagram identical with that of bauxite having the same compn. (böhmite).
Oscar T. Quimby

The preparation of arsenic triiodide by the wet method. Pedro G. Paternosto. *Rev. facultad cienc. quim.* (Univ. La Plata) **7**, 43–6(1930).—A modification of the classical method for prepg. AsI_3 gives a yield of 94 and 99.8% purity. With a pptg. flask 2 g. of pure As_2O_3 was treated with 30 cc. HCl (d. 1.19). Ten g. KI and 10 cc. H_2O were heated and this soln. was poured into the pptg. flask, allowed to react for 4–5 min. and the ppt. was then filtered on asbestos and dried in vacuum. The dried ppt. was extd. several times with CS_2. The AsI_3 was extd., eliminating KCl which is insol. The CS_2 is evapd. off in vacuum and beautiful, hexagonal plates of AsI_3 are obtained.
M. McMahon

Hydrated sulfates containing three metals. B. Gossner and Th. Bäuerlin. *Ber.* **63B**, 2151–5(1930); cf. *C. A.* **24**, 1006.—The mineral voltaite is considered to have the formula: $[KH_3(SO_4)_3]_2.[(Fe, Al)O_3H_3]_3.[FeSO_4]_4.4H_2O$. Nine similarly composed sulfates have been prepd. by replacing (1) the FeO by MnO, CoO, MgO, ZnO or CdO and (2) the K_2O by $(NH_4)_2O$, Rb_2O or Tl_2O and keeping the Fe_2O_3 const. The relation $SO_3:MeO:Me'_2O = 10:4:1$ found for voltaite was found to hold for the entire series. The ratio $SO_3:Fe_2O_3$ varied between 10:1.54 and 10:1.88. In each case the total H equiv. of the 3 metals is approx. equal to that of the SO_3. It is doubtful whether all the salts conform to a single type formula. Only the 3 ferro-voltaites are isotropic. The edge of the elementary cube in each salt is approx. 27.5 A. U. Oscar T. Quimby

Borates. The system Na_2O–B_2O_3–H_2O at 45°. U. Sborgi and L. Amelotti. *Gazz. chim. ital.* 60, 468–74(1930).—The expts. complete data on the system Na_2O–B_2O_3–H_2O (cf. *Z. anorg. Chem.* 50, 38(1906); S. and Mecacci, *C. A.* 9, 2845; 11, 1607; Rosenheim and Leyser, *C. A.* 16, 1194; S. and L., *Atti soc. Toscana sci. nat.* 35 (1926)) and make possible the construction of a polythermic diagram. The *app.* and *technic* are described in detail, and the results are tabulated as well as shown by the diagram mentioned, which should be consulted for details. C. C. Davis

The borates of cesium. A. P. Rollett and L. Andrés. *Compt. rend.* 191, 375–8(1930).—When alc. solns. of H_3BO_3 and Cs_2O are mixed a ppt. forms with a const. compn. of $5B_2O_3.Cs_2O$. It is anhyd. and amorphous. An isothermal diagram of the B_2O_3–Cs_2O–H_2O system at 18° has been detd. up to 35% Cs_2O. This curve shows the presence of 3 distinct compds.: $5B_2O_3.Cs_2O.8H_2O$, small orthorhombic crystals; $2B_2O_3.Cs_2O.5H_2O$, large orthorhombic crystals; $B_2O_3.Cs_2O.7H_2O$, orthorhombic prisms. Amy LeVesconte

The formation and the constitution of lead sodium thiosulfate. B. Oddo and Q. Mingoia. *Gazz. chim. ital.* 60, 501–8(1930).—See *C. A.* 24, 4230. C. C. Davis

Revision of some cases of coördination number 5. The amines of nickel thiosulfate. L. Le Boucher. *Anales soc. españ. fís. quím.* 28, 895–904(1930).—$NiS_2O_3.5NH_3$ prepd. by Ephraim is not a pure substance. Violet $NiS_2O_3.6NH_3$, blue $NiS_2O_3.4NH_3$ and olive-green $NiS_2O_3.2NH_3$ were prepd. and their mol. vols. detd. The hexamine was systematically destroyed by the aid of vapor pressure detns. E. M. Symmes

Complex ammoniacal cobalt molybdates. Priyada Ranjan Ray and Sailendra Nath Maulik. *J. Indian Chem. Soc.* 7, 607–16(1930).—Crystals of the following compds. were prepd. by oxidizing by the passage of a vigorous current of air through a soln. of the Co salt and *N* Na molybdate or molybdic acid in the presence of calcd. quantities of NH_4 salt and NH_3: $[Cl.Co.(NH_3)_5]MoO_4$, insol; $[OH.Co(NH_3)_5]MoO_4.1$ or $2^1/_2$ H_2O, sol.; $[H_2O.Co.(NH_3)_5]_2(MoO_4)_3$, fairly sol.; $[MoO_4.Co.(NH_3)_5]_2MoO_4$, insol.; $[H_2O.NO_2.Co.(NH_3)_4]MoO_4$, sparingly sol.; $[MoO_4.NO_2.Co.(NH_3)_4]$, sparingly sol.; $[SCN.Co.(NH_3)_5]MoO_4$, sparingly sol.; $[NO_3.Co.(NH_3)_5]MoO_4$, sol. W. C. F.

Ammonates of copper selenate. Loren C. Hurd and Victor Lenher. *J. Am. Chem. Soc.* 52, 3857–64(1930).—$CuSeO_4.4NH_3.H_2O$ (I), $CuSeO_4.3NH_3.H_2O$ and $CuSeO_4.4NH_3$ (II) have been prepd. according to the methods of Dennis and Koller (*C. A.* 13, 1567). A new method for prepg. II has been described. I and $CuSeO_4.5H_2O$ absorb NH_3 to produce $CuSeO_4.5NH_3$ although the latter was more easily prepd. by the action of liquid NH_3 on II. If $CuSeO_4.6NH_3$ was formed at all it is not stable at atm. pressure above —33°. By heating II to 178°, $CuSeO_4.2NH_3$ resulted. No evidence was found for the existence of $CuSeO_4.4NH_3.2H_2O$ reported by Lange (*C. A.* 21, 868). W. C. F.

Ammonates of copper selenite. Loren C. Hurd, George I. Kemmerer and V. W. Meloche. *J. Am. Chem. Soc.* 52, 3881–6(1930).—$CuSeO_3.2NH_3.H_2O$ (I) was deposited from an ammoniacal soln. of $CuSeO_3.2H_2O$ (II) upon evapn. at 60° by a rapid stream of NH_3. I was also prepd. by the action of anhyd. NH_3 on II at 25°. Below 10° the passage of NH_3 into an ammoniacal soln. of $CuSeO_3$ gave blue crystals of $CuSeO_3.3NH_3.xH_2O$. Evapn. of solns. of $CuSeO_3$ with excess NH_3 in absence of air gave green $CuSeO_3.NH_3.H_2O$ (III) [cf Boutzaureanu, *Ann. chim. phys.* 6, 18, 346 (1889)]. III also resulted upon exposure of I to air. Desiccation of I over soda lime at 15 mm. gave $CuSeO_3.2NH_3$ (IV). Both III and IV reacted at 0° with NH_3 gas to give $CuSeO_3.3NH_3$. $CuSeO_3.4NH_3$ was obtained from liquid NH_3. The transition point of the system $CuSeO_3.4NH_3$–$CuSeO_3.3NH_3$ falls at —25 ±1°. Green $CuSeO_3.NH_3$ results upon warming all the anhyd. ammonates of $CuSeO_3$ to 120°. W. C. Fernelius

7—ANALYTICAL CHEMISTRY

W. T. HALL

Sulfuric acid salts of aromatic amines as standards in alkalimetry. E. Strasser. *Z. anal. Chem.* 82, 114–6(1930).—Sulfates of aniline, chloroaniline, *p*-anisidine and *p*-toluidine can be used as standards with phenolphthalein as indicator. W. T. H.

Application of light of short wave length to quantitative chemical investigations. J. Eisenbrand. *Pharm. Ztg.* 75, 1033–6(1930).—A discussion of both "strong" and "weak" fluorescence phenomena in connection with certain new reactions. W. O. E.

Advancement in analytical investigation by means of ultra-violet rays. Frank. *Chem. Tech. Rundschau* 45, 841(1930).—The analytical quartz lamp has been found of practical value in identification of alkaloids. *Morphine* can be detected in a dilu.

of 0.001 mg. in 30 cc. of fluid. *Hydrastine sulfate* solns. show an intensive blue-green fluorescence in diln. as great as $1:10^{11}$, the max. being at $1:10^{4}$. By means of fluorescence *quinine* can be detected in the saliva 5 days after administration. From a mixt. of products with known impurities a fluorescence scale can be developed which permits the detn. of the quality so accurately that a difference of 0.001% in ash content is recognizable. This lamp can also be used to differentiate *artificial tanning materials* from those of vegetable origin since the latter do not fluoresce in dilns. of 1:1000. E. P.

Use of the filtration method in volumetric analysis, particularly in the analysis of portland cement. HANS TH. BUCHERER AND F. W. MEIER. *Z. anal. Chem.* **82**, 1–44 (1930).—I. In the absence of Fe, Al and H_2SiO_3, *Ca can be detd.* accurately as follows: To 100 cc. of soln. contg. 0.2 g. or less of Ca, add 1.25–1.5 equivs. of NaOAc, heat to 70–80° and add 0.1 *N* $H_2C_2O_4$ soln. dropwise until further addn. of precipitant produces no further pptn. This is best detd. by adding the reagent, without testing, as long as pptn. obviously occurs, then filtering off a small portion of the soln. and testing with $C_2O_4^{--}$ or with Ca^{++} to det. whether an excess of C_2O_4 has been added. It is best to carry out 2 tests in this way, *i. e.*, add, the second time, nearly the entire amt. indicated by the first test before making any filtration test. II. With oxine as precipitant, the following procedure serves for the *detn. of Mg:* To 100 cc. of soln. contg. 0.12 mg. or less of Mg, add 20 cc. of 2 *N* NH_4Cl and 10 cc. of concd. NH_4OH. Heat to 70–80° and, while shaking and gradually raising the temp. to boiling, add a slight excess of oxine, as shown by the yellow color, and titrate the excess with standard $MgCl_2$ soln. III. For the *detn. of Ca and Mg* in the presence of one another, titrate first as outlined above with oxalic acid and then, without filtering off the CaC_2O_4 ppt., titrate the Mg with oxine, filtering small portions of the soln. to det. whether the pptn. is complete. The method succeeds in the analysis of limestone from which SiO_2 and $Al(OH)_3$ have been removed in the usual manner. IV. The filtration method can also be used to advantage for the *detn. of H_2SO_4 with $BaCl_2$.* Excellent results were obtained in the titration of 100 cc. of soln. contg. 5–120 mg. of H_2SO_4 with 0.1 *N* $BaCl_2$ soln. V. The filtration method can also be used for the *titration of Cu with Na_2S* soln. The titration succeeds in ammoniacal solns., the end point being detd. by testing a small portion of filtered soln. with a drop of the precipitant. In acid solns. the titration succeeds if a trial test is made first. Otherwise there is danger of some H_2S escaping from the soln. VI. The filtration method can also be used for the *titration of Zn with Na_2S or with oxine.* With the former reagent, add 3–5 g. of NaOAc to the faintly acid Zn soln. and titrate at a vol. of 100 cc. at room temp. With oxine the temp. should be about 60° and the soln. should contain 3–6% of free NaOAc. VII. The *titration of Cu and of Zn with Na_2S* succeeds when both are present. Titrate the Cu first at 75°, dilg. to 100 cc., providing 5 milli-equivs. of H_2SO_4 and adding Na_2S until the filtration test shows no more Cu^{++} to be present. Add a few drops of alc. AcSH soln. to make sure that the last traces of Cu are pptd. and boil off the excess H_2S. Filter, wash with hot, dil. H_2SO_4, cool to room temp., neutralize with NaOH (methyl orange), add 3–5 g. of NaOAc and titrate the Zn with Na_2S. VIII. The *pptn. of Mn as $MnNH_4PO_4$* also succeeds by the filtration method. To 100 g. of neutral soln. contg. 10–100 mg. of Mn, add 10 g. of NH_4Cl, make slightly ammoniacal, heat to 75° and titrate with standard Na_2HPO_4. IX. The method proved successful for the *titration of Zn and Mn.* First the Zn was titrated with oxine, then the ppt. was removed by filtration, the filtrate made slightly ammoniacal and titrated in the presence of NH_4Cl as just described. X. The method was also applied to the *detn. of Cu, Zn and Mn in brass.* The Cu was titrated with Na_2S, the Zn with oxine and the Mn with Na_2HPO_4. XI. *Determination of Fe and Al with oxine.*—To 100 cc. of faintly acid soln. contg. 0.12 g. of Fe or less, add 4 g. NaOAc and a measured vol. of oxine acetate soln., as detd. by a preliminary test or by spot tests with diazobenzenesulfonic acid paper. Heat and filter off the Fe ppt. Filter and det. the excess of oxine bromometrically. The same procedure serves for the simultaneous pptn. of Fe and Al; in such a case the Fe can be detd. alone in a sep. sample either iodometrically or by means of $KMnO_4$. XII. *Sepn. of SiO_2 in Ca silicates and analysis of portland cement.*—Considerable exptl. evidence is offered to show that the usual method of detg. SiO_2 in silicates rich in Ca and Mg gives low results and it is recommended in the analysis of cement to treat 1 g. of the strongly ignited cement with 25 cc. of water and 25 cc. of 7.5 *N* HNO_3. Stir well and evap. on the water bath until perfectly dry. Rub the residue with a pestle and dry at 115° until there is no more odor of acid Cool in a desiccator and triturate the dry powder with 10 cc. of a mixt. contg. equal parts of alc. and ether to remove $Ca(NO_3)_2$ and $Mg(NO_3)_2$. Filter through a dry filter and wash the residue with alc. ether until the extn. is complete. Treat the residue with 75 cc. of 10% HCl, evap. to dryness and

dry thoroughly at 115°. Treat this residue also with 75 cc. of 10% HCl, heat on the water bath for 10 min. and filter off the SiO_2. The rest of the analysis follows conventional lines except that the Fe and Al, after one pptn. with NH_4OH, are finally pptd. with oxine and the Mg is also pptd. with oxine as outlined above. The results for SiO_2 are distinctly higher and of Al_2O_3 distinctly lower than those by the usual method. W. T. H.

Micro-iodometry. RUFINA V. TEIS. *Z. anal. Chem.* **82**, 116–22(1930).—See *C. A.* **24**, 4999. W. T. H.

Electrometric titration. LASSIEUR. *Ann. chim. anal. chim. appl.* **12**, 290–6 (1930).—A review of the development and theory of potentiometric titration. W. T. H.

The analytical significance of aging phenomena. HELLMUT FISCHER. *Z. angew. Chem.* **43**, 919–22(1930).—Gelatinous ppts. on being aged consist of larger particles than when freshly formed. The aged ppts. are less sol. and do not adsorb other ions like the unaged gels. Thus a gelatinous ppt. of $Be(OH)_2$ formed in the presence of NaF may yield BeO contg. 23% of adsorbed NaF, but by heating the suspended ppt. in the mother liquor at 80° with a reflux condenser attached to the flask contg. the soln., the ppt. becomes less gelatinous and more nearly cryst., with the result that only 0.5% of NaF will be found in the ignited BeO. The gelatinous hydroxides of Fe, Al and Cr can be sepd. more efficiently from the hydroxides of the bivalent metals if the ppts. are aged before filtering. Heating the soln. is the means commonly adopted to accomplish an artificial aging. Another expedient is to make the ppt. form more slowly under conditions such that the aged and less amorphous ppt., because of its slighter soly., is formed directly as with pptg. hydroxides by adding NH_4NO_2 or $Na_2S_2O_3$. Numerous other practical applications of the principle are pointed out in this interesting paper. W. T. H.

New adsorption indicators for argentometry with a comparison of their limits of sensitiveness. A. J. BERRY AND P. J. DURRANT. *Analyst* **55**, 613–7(1930).—As an adsorption indicator *tartrazine* has been found suitable, better results being obtained than with chrysoidine and "phosphine" which can, like tartrazine, be used in solns. which are 0.5 *N* in acid. When tartrazine is used, the ppt. of AgCl or AgBr assumes a strong yellow color as long as Ag^+ is present in soln. but as soon as a slight excess of halide has been added, the soln. assumes a greenish yellow color. The change is very sharp and is particularly well suited for rapid titrations. In this method the end points, however, occur about 0.1 cc. earlier with 0.1 *N* KBr soln. than in the Gay Lussac method of stopping when no further sign of turbidity is produced, and the results of parallel expts. do not agree quite as well. W. T. H.

Properties of diphenylamine and diphenylbenzidine as oxidation-reduction indicators. I. M. KOLTHOFF AND L. A. SARVER. *J. Am. Chem. Soc.* **52**, 4179–91(1930); cf. *C. A.* **24**, 2078.—In solns. which are 0.1–0.2 *N* in H^+, diphenylamine is oxidized completely to diphenylbenzidine by the slow addn. of $K_2Cr_2O_7$. An excess of dichromate oxidizes it further to a violet quinoid salt which combines quickly with unchanged diphenylbenzidine to form a very difficultly sol., green meriquinoid salt. In titrating the violet soln. with $FeSO_4$, a color change of violet to green occurs at about 0.51 against a satd. HgCl electrode, regardless of the H-ion concn. of the soln. A theoretical explanation is offered to account for this behavior. From a stoichiometric standpoint, the results of this analytical study are hampered by the fact that certain side reactions are likely to occur because diphenylbenzidine and diphenylbenzidine green are very slightly sol. and diphenylbenzidine violet decomposes readily, especially at low H-ion concn. The absorption spectra of oxidized diphenylamine and of diphenylbenzidine solns. are identical. About 0.06 mg. of diphenylbenzidine dissolves in 1 l. of water at 25–50° and its ionization const. is 2×10^{-14}. W. T. H.

Titrimetric determination of the active oxygen in mixtures of hydrogen peroxide and persulfuric acid. G. D. LYUBARSKII AND M. G. DIKOVA. *Z. anal. Chem.* **81**, 450–4 (1930).—Pour 5 cc. of the liquid, such as may be obtained by electrolysis of H_2SO_4, into 150 cc. of cold water and add 5–10 cc. of 10% KI soln. After 24 hrs. standing in a cold, dark place, titrate the I_2 with $Na_2S_2O_3$ soln., carrying out at the same time a blank test without any peroxide present. Results obtained by this procedure are compared with 5 other methods of analysis. W. T. H.

Qualitative test for fluorine in bones. J. AND R. CASARES. *Anales soc. españ. fis. quim.* **28**, 910–5(1930).—The literature is contradictory on F in bones. The corrosive action of HF on glass, and decompn. of SiF_4 by H_2O were studied, defects pointed out, and modifications suggested. To a small quantity of Ag_2SO_4, powd. glass and concd. H_2SO_4, a little bone ash is added, the crucible covered with a watch glass carrying a

drop of $Ba(OAc)_2$ acidified by HOAc. Formation of a ring of SiO_2 or characteristic Ba hydrofluosilicate proves the presence of F. Various bones and marine products were tested. F does not exist in teeth, and there is less in bones of young than in old animals. E. M. SYMMES

Methods for the analysis of red phosphorus. S. A. TOLKACHOV AND M. A. PORTNOV. *Z. anal. Chem.* **82**, 122-33; *Zhur. Prikladnoĭ Khim.* **3**, 605-14(1930).—Red P is likely to contain traces of metal salts, As, H_2SO_4, P acids and a small quantity of yellow P. The detns. of total P, P acids and yellow P present certain difficulties and the expts. described in this paper show that the methods hitherto used are far from satisfactory. The following procedures are recommended: *Total P.* To 0.25 g. of sample in a 100 cc. Philips' flask, add 2-3 cc. of water and then, while heating on the water bath with the flask covered, carefully add small portions of a satd. soln. of Br in concd. HNO_3. White vapors should not form on the surface of the water. This treatment requires about 20 min.; the oxidation is incomplete if it is hurried. Evap. the soln. to a small vol. and add 5 cc. more of the Br-HNO_3. Repeat this treatment with Br-HNO_3. Finally evap. till all acid fumes are removed. Add a little hot water, filter and det. H_3PO_4 in the filtrate in the usual manner, eventually weighing as $Mg_2P_2O_7$. *P acids.* Digest 20 g. of sample in a 250 cc. measuring flask with 20 cc. of 2 *N* H_2SO_4 and water. After digesting 12-15 hrs. with shaking, make up to the mark and filter through linen. To 50 cc. of filtrate add 5 cc. of Br-HNO_3 mixt. and det. the P as described above. *Yellow P.* Cover 15-20 g. of sample in a 100 cc. measuring flask with CS_2 and digest 12-15 hrs. with shaking. Filter into a flask filled with CO_2 and keep the funnel also filled with this gas to prevent oxidation. Take 50 cc. of the filtrate, using CO_2 to empty the pipet into a flask contg. Br-aq. Shake and add more Br unless an excess is present as shown by the color. Distil off the CS_2 on the water bath, using a condenser, and to the residue add Br-HNO_3 and continue as in the detn. of total P. *Detn. of H_2O.* Dry in a vacuum desiccator for 1.5-2 days. W. T. H.

Determination of phosphorus in aluminum. STEINHÄUSER. *Z. anal. Chem.* **81**, 433-8(1930). The difficulties attending the accurate detn. of 0.0005-0.002% of P in metallic Al are shown and a method is developed in which 30-50 g. of metal is dissolved in dil. HCl in an atm. of H_2. The P is liberated as phosphine. The H_2 and PH_3 from the decompn. vessel are burned and the resulting P_2O_5 is collected, partly as a white deposit and partly by absorption in dil. NaOH. Then, to remove SiO_2 from the deposit it is treated with HF and H_2SO_4. The absorbent is treated similarly to remove traces of Si. Finally the P is pptd. with molybdate. It is also shown that the escaping gas from treating Al with HCl may blacken $AgNO_3$ paper as a result of the presence of SiH_4 so that the test cannot be used to indicate the presence of P. W. T. H.

Gravimetric determination of aluminum, chromium and iron by means of potassium cyanate. B. J. F. DORRINGTON AND A. M. WARD. *Analyst* **55**, 625-8(1930).—Ripan's method of detg. Al by means of KCNO (*C. A.* **22**, 3373) has given low and irregular results and, contrary to the statements of R., the ppt. was gelatinous. By washing the ppt., after standing overnight, with a hot, faintly alk. NH_4NO_3 soln. and finally heating 2 hrs. in a muffle, it was found possible to overcome most of the error. Similar difficulties were encountered in the detn. of Cr and similarly overcome. Directions are now given for applying the method to the detn. of Fe. R. has stated the Zn and Mn do not interfere with this method of pptn. but this does not appear to be true. W. T. H.

Volumetric determination of barium by direct titration with potassium chromate solution. S. BALACHOWSKI. *Z. anal. Chem.* **82**, 206-10(1930).—For the micro and semimicro detn. of Ba it is recommended to titrate 1-2 cc. of soln. with 0.04 *N* K_2CrO_4 until an indicator, within the range bromothymol blue to phenol red, changes color, showing that the p_H of the soln. has increased by the presence of a slight excess of K_2CrO_4. A *new microburet* is shown which is suitable for the titration. W. T. H.

Gravimetric determination of beryllium by means of hydrazine carbonate. A. JILEK AND J. KOTA. *Collection Czechslov. Chem. Comm.* **2**, 571-83(1930).—Hydrazine carbonate has certain advantages over NH_4OH and $(NH_4)_2CO_3$ as a precipitant for $Be(OH)_2$ or Be basic carbonate. The ppt. is less slimy and less sol. in a slight excess of the precipitant. To 100 cc. of soln. contg. not over 0.1 g. of Be, in 100 cc. add 5 g. of NH_4 salt and, while boiling, a slight excess (2-3 cc.) of hydrazine carbonate soln. Allow the ppt. to stand 2 hrs., filter and wash with 0.5-1.0% NH_4NO_3 soln. which has been made neutral to methyl red. Ignite and weigh as BeO. W. T. H.

Potentiometric determination and separation of chromium, vanadium and molyb-

denum with respect to steel analysis. W. TRZEBIATOWSKI. *Z. anal. Chem.* **82**, 45–61 (1930).—See *C. A.* **24**, 5000. W. T. H.

Two sensitive color tests for cobalt. EDWIN EEGRIWE. *Z. anal. Chem.* **82**, 150–4 (1930).—Eriochromblueblack B(G) and eriochromred B(G) serve for the detection of very small quantities of Co. The former gives a reddish violet soln. and when treated with nitrite and AcOH becomes yellowish brown or orange. If Co is present the violet color persists or, if considerable Ni is present, a transient brownish yellow coloration is first obtained but on standing violet color appears. As reagent, dissolve 0.01 g. of the dye in 50 cc. of water. To test a soln. for Co, add 5–10 drops of the reagent, 1 drop of nitrite soln. and a slight excess of 0.5 *N* AcOH. As little as 0.001 mg. of Co can be detected in 1 cc. of total vol. With the latter dye, the procedure and concn. of reagents are the same. The aq. soln. of this dye is reddish yellow on being treated with nitrite and AcOH. The color is orange when Co is present. This test is delicate if Ni is first removed which can be accomplished as follows: To a drop of Ni soln. add 1.5–2 cc. of 5 *N* NaOH contg. 10% of glycerol by vol. Boil a short time and filter. Make the filtrate acid by adding concd. HCl, neutralize with solid $NaHCO_3$, add 5–10 drops of dye soln., then 2 drops of nitrite soln. and make acid with 0.5 *N* AcOH. In this way the presence of 0.0005 mg. Co can be detected in a soln. which originally contained 10,000 times as much Ni. W. T. H.

Quantitative precipitations at extreme concentrations. II. Determination of magnesium. N. NJEGOVAN AND V. MARJANOVIC. *Z. anal. Chem.* **82**, 154–61(1930); cf. *C. A.* **22** 1927.—The following procedure has been evolved as a result of 72 expts. which are described in this paper: Evap. the soln., contg. not over 0.3 g. of MgO as sulfate or chloride, to dryness in a 300–400 cc. beaker. Cool, add 5 cc. of concd. H_2SO_4 and heat until all chloride or oxalate is removed. Cool, add 15–25 cc. of cold, satd. Na_2HPO_4 soln. and a few drops of phenolphthalein indicator. Then, while shaking, add at one time enough of a mixt. of equal parts concd. NH_4OH and 96% alc. to make the soln. red. Dil. with 150–200 cc. of water and heat 1 hr. on the water bath. Cool, filter through a Berlin filtering crucible through which water has been passed three times. Wash the ppt. with 2.5% NH_4OH until all sulfate is removed and ignite in an elec. oven to const. wt. ($Mg_2P_2O_7$). W. T. H.

The permanganate determination of molybdenum. TH. DÖRING. *Z. anal. Chem.* **82**, 193–206(1930).—Steel chemists of the U. S. A. have known for over 30 yrs. that an acid soln. of molybdate can be reduced completely to the tervalent condition by passage through a Jones reductor and if the reductor contains ferric alum soln., the reduced Mo is oxidized partly, leaving an equiv. quantity of Fe^{++} so that when the soln. is titrated with $KMnO_4$, the consumption corresponds to the vol. required theoretically to convert the tervalent Mo back to molybdic acid. This method was worked out in the lab. of the Penn. R. R. by Dudley and Pease toward the end of the 19th century but was not published at that time. For some reason, the method has never been well known in Europe. In the present paper a careful, critical examn. of the method is described and the advantages over other procedures are acknowledged. It is unnecessary to work in an atm. of CO_2 or to hurry in titrating the reduced soln. W. T. H.

Analytical application of catalytic reactions: Characteristic test for palladium. F. FEIGL AND P. KRUMHOLZ. *Ber.* **63B**, 1917–9(1930).—Metallic Pd, formed by reduction of a Pd salt by CO, reduces molybdates or phosphomolybdic acids to Mo blue. A rapid stream of CO is passed through a boiling acid soln. of Pd salt and phosphomolybdic acid; in a few min. a blue to green color appears. This is true only of Pd among the Pt metals. Au, Hg or Fe^{++} decreases the sensitivity of the test. Ag, Pb, Cu, Cd, Sb, Sn, Ni, Co, Zn, Al, Ca, Mg, Na and K in 0.5 *N* HCl soln. in concn. of less than 0.25–1.0% do not effect the test. 0.025 γ Pd in 1 cc. can be detected. 0.5 γ Pd with 1000 times this amt. Ru, 0.25 γ Pd with 4000 times this amt. Os or 8000 times this amt. Ir can be detected. S. LENHER

Determination of potassium in very dilute solutions and in soil extracts. MARGARETHE V. WRANGELL (Princess Andronikow). *Z. anal. Chem.* **82**, 224–6(1930).—Detailed directions are given for pptg. the K as $K_2Na(NO_2)_6$ and detg. the NO_2 content of the centrifuged ppt. colorimetrically by means of a soln. prepd. from indole and H_2SO_4. W. T. H.

Notes on the analytical chemistry of rhenium. I. Determination of soluble perrhenates with the aid of nitron. W. GEILMANN AND A. VOIGT. *Z. anorg. allgem. Chem.* **193**, 311–5(1930).—In slightly acid soln. contg. $KReO_4$, nitron acetate soln. ppts. insol. nitron perrhenate; 17–18 mg. of the salt dissolves in 100 cc. of pure water but in the presence of 0.3–0.5% nitron acetate, the ppt. is practically insol. and well

adapted for the detn. of Re. To the neutral soln. of perrhenate contg. not more than 0.1 g. of Re, add hot water to make 50 cc. and 1 cc. of 2 *N* H_2SO_4. Heat to 80° and add enough of 5% nitron acetate soln. to make the soln. contain 0.3–0.4% of free nitron at the end. Cool for 2 hrs. in ice water, stirring frequently and vigorously. Filter and wash with ice-cold, 0.3% nitron soln., using as little as possible. Finally wash with water that is satd. with nitron perrhenate, dry 2 hrs. at 110° and weigh. The ppt. contains 33.06% Re. W. T. H

Direct determination of sodium in the presence of aluminum and chromium. EARLE R. CALEY AND DARREL V. SICKMAN. *J. Am. Chem. Soc.* 52, 4247–51(1930).—A slightly modified technic is described for pptg. Na as $NaMg(UO_2)_3(OAc)_9.6.5H_2O$. The procedure is applicable to the direct detn. of Na in a soln. contg. Al^{+++} and Cr^{+++} but a high concn. of NH_4^+ should be avoided. W. T. H.

Investigations into the analytical chemistry of tantalum, columbium and their mineral associates. XVIII. New method for the separation of titanium from zirconium and hafnium. A. R. POWELL AND W. R. SCHOELLER. *Analyst* 55, 605–12(1930); cf. *C. A.* 24, 1055.—The best way to sep. Ti from Zr is generally regarded to be that of pptg. $ZrHPO_4$ in the presence of H_2SO_4 and H_2O_2 which keep Ti in soln. as pertitanic acid. Dittrich and Freund (*C. A.* 2, 1250) published a method based on the formation of a sol. Ti complex of salicylic acid. A re-investigation of the latter method, which does not appear to have received comment in the literature, was undertaken and the conclusion drawn that it is not strictly accurate, although more effective than the sepn. recommended by Noyes and Bray. Better than either of these methods is the method now proposed which is based on the pptn. of TiO_2 by tannin from a neutralized oxalate soln. which is half satd. with NH_4Cl. Under the conditions recommended, Zr remains in soln. although U is pptd. Fuse the mixed oxides, contg. not over 0.1 g. of TiO_2, with $K_2S_2O_7$ in a silica crucible and dissolve the melt in 75 cc. of 3% $(NH_4)_2C_2O_4$ soln. in a 600 cc. beaker. To the boiling soln. add *N* NH_4OH till a slight cloudiness is produced and dissolve this immediately by adding a little *N* HCl. Add an equal vol. of satd. NH_4Cl soln. (29%) and continue boiling. Add the precipitant (a freshly prepd., filtered 4–5% tannin soln.) dropwise from a buret while stirring, using about 12 times as much tannin by wt. as there is TiO_2 present. Allow the beaker to remain on the hot plate until the flocculent, red ppt. has settled, leaving the liquid clear. If the latter is at all orange, more tannin must be added. Digest on the hot plate for less than an hr. Filter the ppt. (P_1) with moderate suction and wash with a soln. contg. 5% NH_4Cl and 1% $(NH_4)_2C_2O_4$. Test the filtrate (F_1) by carefully neutralizing with NH_4OH and adding tannin soln. dropwise until a slight pptn. takes place. If this is a dirty gray the Ti pptn. is probably complete but if yellow or orange, Ti is still present and must be removed by adding more tannin. Ignite the P_1, wet in a porcelain crucible and dissolve the melt in 75 cc. of 3% $(NH_4)_2C_2O_4$ soln. Filter the hot soln. for the removal of traces of grit and CaC_2O_4. Treat as before, using 12 times as much tannin as the wt. of P_1. Test the filtrate (F_2) for complete pptn. of Ti. Ignite the ppt. and weigh as TiO_2. Boil the combined filtrates ($F_1 + F_2$) with a large excess of HNO_3 and H_2SO_4 for the removal of NH_4Cl, oxalate and tannin, finally fuming till all HNO_3 is removed. Cool, dil. with water, neutralize somewhat with Na_2CO_3, filter and ppt. the Zr in the filtrate by boiling with $Na_2S_2O_3$. Ignite and weigh as ZrO_2. W. T. H.

The flame test for tin. FR. L. HAHN. *Z. anal. Chem.* 82, 113–4(1930).—This test, recently described as new by Meissner (*C. A.* 24, 3966), has been known for at least 29 yrs. M.'s conclusion that SnH_4 is formed in the test seems doubtful for the test can be obtained when a large excess of O is present. It does, however, furnish a sensitive method for detecting SnH_4 in H_2 gas. A bright test with very little Sn present can be obtained only when the water in the test tube, which is held in the non-luminous flame, is distinctly above room temp. It seems probable that the test can be used for the detection of halogen as well as for Sn. W. T. H.

New iodometric method for determining vanadium in alloy steels and in ferrovanadium. W. WERZ. *Z. anal. Chem.* 81, 448–50(1930).—In a 500 cc. Erlenmeyer flask, treat 1–3 g. of filings with 50 cc. of H_3PO_4, d. 1.70, 170 cc. of water and 5 cc. of 6 *N* HNO_3. Boil gently until all of the metal has dissolved. Oxidize the soln. with concd. HNO_3 and add 0.5–1 g. of $(NH_4)_2S_2O_8$. Boil 15 min. to decomp. the excess persulfate. Cool to about 70° and decomp. $HMnO_4$ by adding 5–10 cc. of 1% oxalic acid soln. Cool to room temp., add some KI, shake and after 5 min. titrate with $Na_2S_2O_3$. For Fe-V, use 1 g. of sample dissolved in 25 cc. of HNO_3. Make up to 500 cc. and take 50 cc. for further analysis. Add 75 cc. of H_3PO_4, 100 cc. of water and persulfate, etc., as above. The reduction of the V is from the quinquevalent to the quadrivalent state.

No data are given to show the accuracy of the method which appears to be easier to carry out than the hitherto-described procedures. W. T. H.

Observations on the rare earths. XXXVI. Separation of ytterbium by electrolytic reduction. ROBERT W. BALL AND L. F. YNTEMA. *J. Am. Chem. Soc.* **52**, 4264-8

dil.

single operation, it is possible to obtain [illegible] material contg. only 2% of Yb. The ppt. is light green, dissolved in dil. non-reducible acids with evolution of H_2 and in HNO_3 with evolution of NO. W. T. H.

Volumetric determination of certain rare metals by means of visual conductivity titration. E. ROTHER AND G. JANDER. *Z. angew. Chem.* **43**, 930-3(1930).—Na_2MoO_4 soln. (about 0.04 molal) can be titrated conductometrically with 0.1 molal $Pb(OAc)_2$. A soln. of Na_2WO_4 (approx. 0.01 molal) can be titrated conductometrically with 0.2 molal $Pb(NO_3)_2$ soln. A soln. of $Tl(SO_4)_2$ (approx. 0.1 molal) can be titrated conductometrically with 0.07 molal Na_2CrO_4 soln. or with 0.2 *N* NaI soln. The results are a little low in the last case because of the appreciable soly. of TlI_2. The breaks in the titration curves were sharply defined in all cases. W. T. H.

Sulfur monochloride studies. III. A new method for determining total chlorine and sulfur in a naphtha solution of sulfur monochloride. HIDEMARO ENDOH. *J. Soc. Chem. Ind.* (Japan) **33**, Suppl. binding 287-90(1930); cf. *C. A.* **23**, 4905.—A 10-cc. sample of a naphtha soln. of S_2Cl_2 is treated with 50 cc. of 1% $NaNO_3$, 20 cc. of 10% $CuSO_4$ soln. and 50 cc. water. Decompn. ensues and excess of naphtha is removed by careful heating. Elementary S is removed by filtration, HNO_3 is added, the soln. is boiled and then treated with $AgNO_3$. Cl is detd. as AgCl. Total S is detd. by soln. of a 10-cc. sample in 20 cc. of glacial HOAc, addn. of 2.5 cc. of pure Br_2 and 70 cc. of warm water. The flask is heated for 1 hr. on the water bath and then over the Bunsen flame to remove all naphtha and HOAc. The soln. is filtered and S detd. as $BaSO_4$. Total S may also be detd. by Weber's Na ethylate method. **IV. A new method for determining chlorine and sulfur in sulfur monochloride.** *Ibid* 290-2.—The Dubosc method may be modified for application to the detn. of Cl and S in S_2Cl_2. A 30-cc. portion of a $AgNO_3$-satd. HNO_3 soln. is allowed to react with the S_2Cl_2 sample in HOAc. After the sample has been fumed down twice with concd. HNO_3, 100 cc. of H_2O is added, and the pptd. AgCl filtered, dried and weighed. To the filtrate HCl and crystals of KNO_3 are added and the soln. is evapd. to dryness, the residue taken up in water and HCl and the S are pptd. as $BaSO_4$. **V.** *Ibid* 292.—In the detn. described in IV the sample of S_2Cl_2 need not be dissolved in HOAc, but may be used directly. L. F. A.

The quantitative precipitation of calcium oxalate in the presence of the arsenate ion. J. T. DOBBINS AND W. M. MEBANE. *J. Am. Chem. Soc.* **52**, 4285-8(1930).—The formation of CaC_2O_4 in the presence of AsO_4^{---} did not take place as readily as in the presence of PO_4^{---} (cf. *C. A.* **24**, 2401), especially at low temp. Accurate results were obtained, however, by the following procedure: Make the soln. alk. with NH_4OH, adding a few drops in excess. Add an excess of $(NH_4)_2C_2O_4$ and boil gently for 10 min. After standing for an hr., filter, wash with very dil. NH_4OH and titrate the CaC_2O_4 with $KMnO_4$ in the usual manner. W. T. H.

Possible sources of error in determining nitrate by the method of Grandval-Lajoux. B. A. SKOPINTZEV. *Zhur. Prikladnoi Khim.* **3**, 747-58(1930).—Evapn. of the standard KNO_2 on a water bath heated with a gas burner leads to a loss of nitrates because of the presence of S compds. in the gas. This is avoided by adding 0.5-1.0 cc. 0.1 *N* NaOH to the soln. The sample of the standard soln. should be 1-3 cc. and the buret must read within 0.01 cc. Presence of NH_3 compds. is harmful only if their content is higher than the equiv. amt. of alkalies. V. KALICHEVSKY

Titrating sodium arsenate solutions. E. V. CHRISTENSEN. *Arch. Pharm. Chemi.* **87**, 350-8(1930).—The titration method for $Na_2HSO_4.7H_2O$ solns. in Dan. Pharm. gives values 1% higher than gravimetric detns. Increasing $AgNO_3$ and Na_2CO_3 increases the titration figures. If $AgNO_3$ soln. is limited to 0.5 cc. in excess of stoichiometric requirements the titrations will be very satisfactory. A. R. ROSE

[illegible] of expts. testing various methods for detg. HNO_3 and HNO_2 in concd. H_2SO_4, the conclusion is drawn that it is advisable to det. the total N by reducing the suitably neutralized soln. with Devada's alloy and KOH, eventually titrating the NH_3 formed. HNO_2 is best detd. by the colorimetric method with *m*-phenylenediamine. W. T. H.

The combination of phosphoric acid with stannic acid and its precipitation in

chemical analysis. ALBERT KRÜGER. *Z. anal. Chem.* **82**, 62–8(1930).—The classic method of removing H_3PO_4 in qual. analysis by treating with Sn and HNO_3 has been assumed by some to depend upon the formation of $Sn_3(PO_4)_2$ and by others to depend upon the adsorption of H_3PO_4 by β-stannic acid gels. Probably neither of these assumptions is correct for the exptl. evidence here described makes it seem probable that α-stannic acid forms an insol. complex acid with H_3PO_4, somewhat of the same nature as phosphomolybdic acid, which is well known in the form of its NH_4 salt. In this case the mol. ratio of Sn:P is much smaller than that of Mo:P for the insol. ppt. appears to have the compn. indicated by the formula $SnO_2.P_2O_5.8H_2O$ and the name *stanniphosphoric acid* is proposed because a similar stannous compd. is known of the formula $5SnO.2P_2O_5.4H_2O$. The ppt. of stanniphosphoric acid is white and voluminous but not slimy. It dissolves in HCl soln. but is insol. in HNO_3. It is also sol. in concd. H_2SO_4 and from this solvent it is pptd. by diln. in the form of a powder. When exposed to the action of OH^- by adding NH_4OH or NaOH, alkali salts of phosphoric and stannic acids are formed. The knowledge of these facts enables one to modify the Sn method for removing PO_4^{---} so that only about 1/6 as much Sn is required. If much Fe is present, it must be removed, preferably by shaking the $FeCl_3$ soln. with ether as recommended by Rothe. To remove PO_4^{---} from the filtrate from the usual H_2S pptn. when only a little Fe is present, evap. the soln. nearly to dryness, add HNO_3 and repeat the evapn. twice more to remove all HCl. Finally add more HNO_3, take up with water, add a drop of NH_4OH and boil for a few min. Cool and add sufficient $Sn(NO_3)_2$ soln. to furnish 3Sn to 1P (1. g SnO dissolved in 100 cc. of 15% HNO_3 at 50°). Add 5 cc. of fuming HNO_3, evap. to pasty consistency, dil. with hot water and heat for some time. If a filtered portion of the soln. gives a test with molybdate, a little more NH_4OH must be added and the treatment with $Sn(NO_3)_2$, etc., repeated. In the final filtrate, a little Sn will be found which can be removed by adding some NH_4OH and satg. the dil. soln. with H_2S. In qual. anal. probably the basic acetate sepn. will be preferred when considerable Fe is present. W. T. H.

Analysis of phosphorous acid. I. N. BUSHMAKIN AND E. P. LOPATIN. *Zhur. Prikladnoĭ Khim.* **3**, 615–22(1930).—The most reliable method is that of Schwicker (*C. A.* **23**, 5438). V. KALICHEVSKY

Volumetric determination of silicic acid in silicates. N. A. TANANAEV AND A. K. BABKO. *Z. anal. Chem.* **82**, 145–50(1930); cf. *C. A.* **24**, 5447.—Fuse the sample with K_2CO_3, using 4 g. of flux for 0.4 g. of kaolin or 0.3 g. of feldspar. Transfer the melt to a Pt dish, using not more than 20 cc. of water. Add 20 cc. of concd. HCl and, after the mixt. has cooled somewhat, add 2 g. of NH_4F. By this treatment a soln. contg. H_2SiF_6, HF and HCl is obtained. After allowing to stand for some time, filter off the K_2SiF_6 ppt. with the aid of a paraffined funnel and wash with a satd. soln. of K_2SiF_6. Place the ppt. and filter in a conical flask, add 20 cc. of 4 *N* $CaCl_2$ soln. and enough water to make 75–100 cc. Heat on the water bath, add methyl red indicator soln. and titrate with 0.5 *N* NaOH. The end of the titration is recognized by the change of color or by the coagulation of the ppt. Carry out a blank test with all the reagents used. The reactions upon which the titration is based is: $SiF_6^{--} + 3Ca^{++} + 4OH^- = 3CaF_2 + Si(OH)_4$. The results appear to be within 0.3–0.4% of the truth in the analysis of materials contg. 43–78% SiO_2. W. T. H.

Micro method for the determination of highly unsaturated fatty acids. H. TANGL. *Biochem. Z.* **226**, 180–4(1930).—The method consists in brominating a mixt. of unsatd. fatty acids, the reaction with Br_2 being more complete and more rapid than with I_2. The various Br_2 addn. products of fatty acids have different solubilities. The product is ashed in a Tschopp app., the halogen being received in H_2O_2 soln. To 5 cc. blood or serum in a 100 cc. flask add dropwise an alc.-ether mixt. (Bloor) and allow to stand at room temp. for 6 hrs. To the filtrate add a 3% soln. of Br_2 in glacial AcOH dropwise until the color remains, and after 12–24 hrs. filter off the ppt., wash the filter and ppt. with a few cc. of hot benzene which removes all fatty acid bromides with less than 8Br atoms. Transfer the paper and residue to the Tschopp oxidation app. contg. 5 cc. of 0.01 *N* $AgNO_3$. After closing the app. add 1 cc. H_2O_2 and 2 cc. concd. HNO_3. Lead the escaping Br vapor into H_2O_2. The oxidation is complete in 30 min. when the Br-H_2O_2 is allowed to flow into the flask. After the further addn. of 1 cc. 1% starch titrate with 0.01 *N* I_2. In blood after a day's fasting the triarachidonate content is 0.016–0.022%. Data are also reported on the triarachidonate content of different tissues. S. MORGULIS

Rapid method for the analysis of brass and copper. W. KOLLREPP. *Z. Ges. Giessereipr.* **51**, 60(1930); *Chimie & industrie* **24**, 601(1930).—The method described is similar to a procedure commonly used except that Cu is detd. by difference. The

sample is dissolved in HNO_3, any residual SnO_2 is filtered off and weighed, the Pb is pptd. as $PbSO_4$ and the Cu pptd. as a sulfide with H_2S. The sulfide ppt. is discarded, the Fe^{++} is oxidized and pptd. as $Fe(OH)_3$, then the Ni is detd. on the dimethylglyoxime and finally the Zn is pptd. as ZnS and weighed as ZnO. A. P.-C.

Volumetric determination of the fluoride ion. A. KURTENACKER AND W. JURENKA. *Z. anal. Chem.* **82**, 210–7(1930).—*Titration with Al salt.*—When a soln. of a sol. Al salt is added to a soln. contg. F^- the following reaction takes place: $6\,F^- + Al^{+++} = AlF_6^{---}$. If methyl red is present, it will show an acid reaction as soon as an excess of Al salt has been added. Dissolve $^1/_6$ mole of $AlCl_3.6H_2O$ in 1 l. of water and filter if necessary. Test to see if any free acid or base is present as follows: Add 20 cc. of the Al soln. slowly to 10 cc. of an approx. 8% soln. of KF which has been made neutral to phenolphthalein. If free acid is present, the soln. will remain colorless; in this case titrate with *N* NaOH soln. until the pink phenolphthalein color is obtained. If free base is present, as is usually the case, the soln. is colored a deep red and direct titration with acid does not give a good result because of the formation of basic double fluorides. Add, therefore, a measured excess of *N* acid and titrate back with *N* NaOH. In accordance with the result obtained in this preliminary expt., add NaOH or HCl to the Al soln. and repeat the above test; a barely perceptible reddening should take place and the color should disappear when 5 cc. of the soln. is treated with 1 drop of 0.1 *N* HCl. It is better to leave the $AlCl_3$ soln. barely alk., rather than slightly acid. Allow the $AlCl_3$ to stand a week or two before using or age it by boiling for a short time. To det. the titer of the $AlCl_3$ soln. prep. a soln. of known F^- content by taking about 1.5 g. of pure 35% HF in a Pt dish and titrating with carbonate-free NaOH. Take a measured vol. of the F^- soln., dil. to 50–100 cc., add an excess of NaCl so that some will remain undissolved at the end of the titration, add methyl red, heat to 70–80° and titrate with the $AlCl_3$ soln. until a permanent red coloration is obtained. In the titration of an unknown F^- soln. proceed similarly, first making the soln. neutral to phenolphthalein, which requires particular care if carbonates are present. In that case it is better to use methyl red in the preliminary neutralization and toward the end heat to 30–40°. The above method serves for the titration of 0.02 g. or less of F^-. It is unsuccessful if phosphates, borates or any acid forming an insol. salt with Al is present. *Titration with Ce^{+++} soln.*—In this case insol. CeF_3 is formed. The method is sensitive to the presence of SO_4^{--}. The procedure is similar to that outlined above. *Titration with H_3BO_3.*—The procedure is based on the following reaction: $4\,F^- + H_3BO_3 = BF_4^- + 3OH^-$. Prep. a satd. soln. of H_3BO_3. Take 15–30 cc. of the F^- soln., neutralize with phenolphthalein and add an excess of H_3BO_3 soln. Add an equal vol. of alc. and 10–20 g. of KCl. Titrate at room temp. with *N* acid, using methyl orange as indicator. W. T. H.

The use of copper tubes in organic elementary analysis. N. KLATSCHIN. *Z. anal. Chem.* **82**, 133–44(1930).—The substitution of Cu tubes for glass tubes in org. combustions is warmly recommended. The work is easier and less time is required. One Cu tube will serve for at least 25 combustions. If the substance contains N, halogens or small quantities of S, the tube should contain, besides the usual CuO layer, some $PbCrO_4$-pumice and a mixt. of PbO_2, finely divided Ag and asbestos. The stoppers at the end of the tube are kept at about 90° by means of hot water jackets near the ends of the tube; there is then no condensation of H_2O in the tube and the stoppers do not burn. A secondary stream of O_2, or air, is provided by making a small opening near the back end of the tube. In heating the tube, one starts at the CuO filling and goes step by step toward the boat and not in the reverse manner as is frequently done. The disadvantage of not being able to watch the combustion is more than compensated by the use of a higher temp. which results in more perfect oxidation. Full details are given. W. T. H.

New reaction for formic acid. M. MASRIERA. *Anales soc. espan. fis. quim.* **28**, 916–31(1930).—The sample is dissolved in the least possible amt. of cold Et_2O or $CHCl_3$, 2 vols. of petroleum ether and then a little $PbNH_2$ are added. Crystn. of white needles, m. 64°, shows the presence of HCO_2H. The distribution coeffs. of HCO_2H and HOAc in Et_2O-H_2O and $CHCl_3$-H_2O, and extn. of aq. HCO_2H and HOAc by Et_2O were detd. These processes are not quant. Various theoretical possibilities of the reaction are suggested. E. M. SYMMES

Volumetric determination of acetone. ANDRE MEYER AND SUZANNE MATHEY. *Compt. rend.* **191**, 490–3(1930).—The method depends upon the pptn. of the acetone with an acid soln. of $HgSO_4$ and detg. the excess Hg by titrating with KCNS. The method of Denigès is used for the pptn. As reagent, use a soln. obtained by dissolving 50 g. of HgO in 200 cc. of concd. H_2SO_4 and dilg. to 1 l. In a flask, mix 25 cc. of

reagent with an equal vol. of the soln. contg. acetone and heat on the water bath for 10 min. Cool, filter off the acetone ppt. and wash with water. Dil. to, say, 100 cc. and take 0.1 for the titration of the Hg with KCNS, ferric alum being used as indicator. Det. the concn. of the reagent in the same way. According to D. the formula of the ppt. is ($2\ HgSO_4.3HgO_3$) $4C_3H_6O$ but Van Slyke gives the formula $3HgSO_4.5HgO.2C_3H_6O$. The method has been used for aq. solns., solns. in MeOH, com. acetone, acetone in urine, etc. The assumption that the ppt. contain 28% acetone seems to give the best results. W. T. H.

Systematic study of the reaction of diphenylbenzidine in sulfuric acid solution with nitrates in the presence of chloride. Comparison with the diphenylamine test. H. RIEHM. *Z. anal. Chem.* **81**, 439–47(1930); cf. *C. A.* **24**, 5670.—The similarity of the 2 tests is pointed out. The resulting color is deeper and the shade more bluish violet, as it should be, the greater the concns. of H_2SO_4, nitrate and chloride and the lower the concn. of excess diphenylbenzidine. Rise in temp. makes the test for nitrate more delicate. The permanence of the color obtained depends upon the ratio of reagent to the nitrate content. In comparison with the diphenylamine test, the depth of color is about twice as great and the stability of the violet-blue color is much more sensitive to the presence of excess diphenylbenzidine. For these reasons the diphenylamine test for nitrate is preferable except when it is desirable to have a somewhat greater sensitivity and a more rapid reaction. W. T. H.

Bromo-potentiometric titration of β-naphtholsulfonic acids in presence of each other. I. Shaeffer acid, R. acid and G. acid. STANLEY D. FORRESTER AND DAVID BAIN. *J. Soc. Chem. Ind.* **49**, 410–2T(1930).—The G. salt in soln. does not brominate at room temp. in the presence of sufficient H_2SO_4. Shaeffer and R. salts monobrominate quantitatively in H_2SO_4 soln. at room temp. and can be titrated in the presence of G. salt with standard bromide-bromate soln. if the initial concn. of H_2SO_4 is 10 *N*, the end point being detd. potentiometrically. The method is described in detail and typical titration curves are shown. W. T. H.

Production, application and detection of MeOH and isopropyl alcohol (BODENDORFF) **16**. Galician W ores (PARGO, ARANGO) **9**.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Hydrothermal experiments on solubility, hydrolysis and oxidation of iron and copper sulfides. FRED FOREMAN. *Econ. Geol.* **24**, 811–27(1929).—The manner in which metallic sulfides are carried in hydrothermal solns. has been a question to geologists, and the object of these expts. was to measure the solubilities of Fe and Cu sulfides under conditions similar to those of their transportation in hydrothermal solns. Previous work is reviewed, expts. are described in detail and tables are given to show results. Conclusions: In the presence of H_2O, formation of Fe or Cu sulfides, oxides or hydroxides depends on the possibility of escape of the generated gases. When sulfide is in contact with H_2O, H_2S is generated at 150–250°. The solubilities of pyrite, pyrrhotite and chalcocite in hot water are very small. Sulfides are not dissolved to any extent by 0.1 *N* $NaHCO_3$ or Na_2S solns., and pyrite does not dissolve in more concd. solns. of Na_2S. The presence of H_2S does not increase the soly. of the sulfides, but actually prevents it. Iron and cuprous sulfides are not carried in igneous solns. as such at the temps. of the expts., nor does Fe seem to be carried as an alk. double sulfide, unless it be in enormously concd. alk. sulfide solns. It seems probable that the Fe was carried as some other compd. and pptd. by chem. reaction with a S compd. as the sulfide. ALICE W. EPPERSON

A diabase contact-metamorphic mineral deposit in Ontario. FRELEIGH F. OSBORNE. *Econ. Geol.* **24**, 722–32(1929).—Reduction of ferric compds. in the presence of limestone is indicated. O. concludes that the quartz magma intruded the Huronian rocks, and the volatile constituents altered it to an amphibolite. The emanations escaped, altering the country rock to form metamorphic silicates. Ferric salts were reduced to magnetite by the action of limestone. The deposit is unusually telescoped. The magnetite is similar to that of the Cornwall Dist., Pa., and Iron Springs, Utah. Pyrite-chalcopyrite and sphalerite-galena zones show features in common with Siberian deposits. The Co zone has striking similarity to deposits of Cobalt, Ontario. ALICE W. EPPERSON

Geology and ore deposits of Boulder Belt, Kalgoorli. F. L. STILLWELL. Geologi-

cal Survey Western Australia, *Bull.* **94**, 110 pp.(1929).—The rocks surrounding the Boulder Belt are ancient sediments, older and younger green-stones, porphyrites, jaspers and graphitic schists. A relationship exists between the lodes and the acid and basic forms of the porphyry dikes. The lode frequently clings to the wall of a dike. The dip of the lode is generally steep and is rarely less than 70°. The main hope of the future discovery of payable ore at depth lies at the southwestern end of the field. A. E. MIX

Gold deposits of the Guayana highlands, Venezuela. W. H. NEWHOUSE AND GUILLERMO ZULOAGA. *Econ. Geol.* **24**, 797–810(1929).—The features of the Venezuelan deposits are described, and the presence of similar features in connection with the Au belt in the Guianas is pointed out. The source of the Au in the Venezuela-Guiana region is considered the closely assocd. diabase rocks. It is stated that the Au-bearing solns. probably came from a magma chamber that had just given off rhyolite-porphyry. Occurrence of tourmaline suggests that the more siliceous intrusives are closely related to the Au veins. ALICE W. EPPERSON

Economic relations of silver to other metals in argentiferous ores. CHARLES W. MERRILL, *et al.* Bur. Mines, *Econ. Paper* **10**, 29 pp.(1930).—The % of total world Ag production contributed by ores whose Ag content represents the indicated proportion of the value of the ore is: Ag 0–10% of ore value, 12.3% total Ag production; 10–20, 21.0; 20–30, 10.3; 30–40, 9.0; 40–50, 5.0; 50–60, 1.7; 60–70, 5.4; 70–80, 8.3; 80–90, 16.9; 90–100, 10.1, resp. More than half the total Ag production is from ores to which Ag contributes $< 1/2$ its value and $1/3$ from the 0–20% classes. A table shows the % of value contributed by each of the other metals in the above classes. Analyses of ores by countries and districts are given. ALDEN H. EMERY

Studies of the origin of the Wabana iron ore of Newfoundland. A. O. HAYES. *Econ. Geol.* **24**, 687–90(1929).—Observations indicate that this ore during formation was exposed to oxidizing conditions in a shallow marine basin. The ferruginous beds are sedimentary, and there is an overlying deposit of oölitic Fe sulfide, free from oxides. The chamosite, a hydrated Fe silicate, was deposited directly from Ordovician sea water, and the same origin is suggested for the hematite, although the possibility is pointed out of the oxidation of the chamosite as a source of the hematite. H. thinks both sources are probable. The mineralogical characteristics and chem. compn. of the ore are given in tables. ALICE W. EPPERSON

Origin of chromite deposits. LLOYD W. FISHER. *Econ. Geol.* **24**, 691–721 (1929).—Chromite ores and minerals assocd. with them throughout the world are described. Origin of chromite is discussed in detail, giving criteria on which conclusions are based. Chem. data indicate that there is no relation between the compn. of chromite and its mode of occurrence, its crystn. or the degree of alteration of chromiferous rock; also that the mineral chromite cannot be expressed by a definite chem. formula. Hydrothermal solns. causing serpentinization have played an important role in the formation of chromite deposits by dissolving magmatic chromite and redepositing it with the hydrothermal silicates. ALICE W. EPPERSON

Deposits of titanium-bearing ores (domestic and foreign). E. P. YOUNGMAN. Bur. Mines, *Information Circ.* **6386**, 41 pp.(1930).—Deposits in 23 states and 46 foreign countries are described. ALDEN H. EMERY

Feldspar. OLIVER BOWLES AND C. V. LEE. Bur. Mines, *Information Circ.* **6381**, 21 pp.(1930).—A general discussion of feldspar is given under the following headings: varieties, phys. properties, origin, occurrence, weathering, uses, specification and tests, mining, milling, grinding capacity, marketing, production centers, foreign deposits, production, imports and exports, tariff, prices and a $2\,1/2$ p. bibliography. A. H. E.

The graphite deposits of Louisa, Quebec. GEO. W. BAIN. *Econ. Geol.* **24**, 733–52 (1929).—The deposits described lie in Wentworth Township in Argenteuil Co., Quebec. The graphite occurs in columnar, flake and massive form. The columnar deposits are assocd. with veinlets of albite and quartz, while the flake form occurs in hydrothermally altered skarn. Geological maps of the region are given, and the deposits are described in detail. B. concludes that the graphite is introduced material, replacing the earlier silicate minerals, the introduction being independent of, and later than, the silication of the limestone from which the skarn was made, and brought about by solns. of silico-alkalic type which are usually responsible for uralitization and chloritization. ALICE W. EPPERSON

Summary of results of investigation on brines and muds of saline lakes in Ukrainia and Kuban regions. E. S. BURKSER. *Ann. inst. anal. phys.-chim.* (Leningrad) **4**, No. 2, 133–62(1930).—An outline is given of methods of chem. and phys. investigation of brines and medicinal muds, their radioactivity and the history of lake formation. ROBERT SCHLESS

Investigations of medicinal mud deposits of the Saki Lake. S. A. SHCHUKAREV, S. K. KOSMAN AND O. M. KOSMAN. *Ann. inst. anal. phys.-chim.* (Leningrad) **4**, No. 2, 163–95(1930).—Analyses of brines and muds are given, as well as other data concerning the lake. ROBERT SCHLESS

Review of work of the Research Laboratory of the Central Administration for social insurance sanatoriums in Evpatoria. A. F. SAGAIDACHNUII. *Ann. inst. anal. phys.-chim.* (Leningrad) **4**, No. 2, 207–16(1930).—Methods of analysis and study of medicinal muds employed at the lab. are outlined. ROBERT SCHLESS

Study of equilibrium in natural soda lakes. Ternary system: sodium sulfate-sodium carbonate-water. N. S. KURNAKOV AND S. Z. MAKAROV. *Ann. inst. anal. phys.-chim.* (Leningrad) **4**, No. 2, 307–63(1930).—There are a no. of lakes contg. Na carbonates in Russia. It is pointed out that efficient production of Na_2CO_3 from these lakes should be preceded by the study of salt equil. and conditions of salt sedimentation at various temps. There are present in these lakes: Na_2CO_3, Na_2SO_4 and NaCl. From the study of the system Na_2SO_4–Na_2CO_3–H_2O, the conclusion is drawn that Na_2CO_3 in crystg. out of soln. will contain Na_2SO_4 in solid soln., and that the most unfavorable temps. for crystn. of pure Na_2CO_3 are 25–50°. The more salts there are in soln. the more Na_2SO_4 will be taken up by the Na_2CO_3. Introduction of one salt into the hydrate of the other, as a solid soln., decreases vapor tension and increases stability. ROBERT SCHLESS

Work of the Karabugaz expeditions. III. Expedition of 1927. B. L. RONKIN. *Akad. Nauk U. S. S. R. Material* No. 73, (*Karabugaz and Its Industrial Importance, 3rd Ed.*) 139–68(1930); cf. *C. A.* **23**, 2396.—The expedition had for its purpose further study of Glauber salt production, its dehydration in natural conditions, impurities in the finished product, investigation of drinking water supply of the region and of transportation of Glauber salt, also investigation of other salt lakes of the region. ROBERT SCHLESS

Rocks of the Pribilof Islands. HENRY S. WASHINGTON AND MARY G. KEYES. *Am. J. Sci.* [5], **20**, 321–38(1930).—The lavas of these wholly volcanic islands are mostly basaltic, with or without olivine. A nephelite-basanite from St. Paul is described. It is shown that trachyte occurs on St. George. ALDEN H. EMERY

Peculiar mud-grains and their relation to the origin of glauconite. JUN-ICHI TAKAHASHI AND TSUGIO YAGI. *Econ. Geol.* **24**, 838–52(1929).—The chem. and mineralogical features of these mud-grains in certain localities around Japan were studied in connection with the origin of petroleum. The mud-grains are widely distributed in estuarine and littoral regions, and are considered the excretions of mud-eaters. They become glauconitized under favorable conditions. Tables showing chem. analyses are given. The origin of glauconite in littoral deposits of different geological ages is thus suggested to be, in part at least, from fossil coprolites. ALICE W. EPPERSON

Cellular structure in limonite. P. F. BOSWELL AND ROLAND BLANCHARD. *Econ. Geol.* **24**, 791–6(1929).—The shape of the cellular pattern in limonite boxwork is governed largely by the fracture pattern inherent to the articular sulfide nodule prior to oxidation. In some cases, as chalcocite and galena, the pattern may be modified by other factors, the nature of which is discussed. Rigidity of the boxwork depends chiefly on the content of supergene silica. Less siliceous types do not survive long unless protected against even mild erosion. Chem. attack, and consequent re-soln., of the cellular boxwork during oxidation of surrounding sulfides is limited because of low soly. of limonitic jasper in acid. ALICE W. EPPERSON

International Nickel Co. LORD MELCHETT. *Mining J.* **170**, 743(1930).—A brief

description is given of the various concentrators and refineries of this Co. in Canada.
ALDEN H. EMERY

Mechanical installations of the lead and zinc district at Letiuche, East Siberia. WÖBLING. *Metall u. Erz* **27**, 497-504(1930).—Power stations, crushing and grinding, and concg. equipment in use at the Pb and Zn mines in this district are described.
H. STOERTZ

Milling method and cost at the conglomerate mill of the Calumet and Hecla Consolidated Copper Co. C. HARRY BENEDICT. Bur. Mines, *Information Circ.* **6364**, 22 pp.(1930); cf. *C. A.* **24**, 5682.—Cu occurs native as the cement in a conglomerate of felsite, feldspar porphyry and quartz porphyry. Complete liberation of values is impossible. Sands are leached and slimes floated. Flotation reagents are Na xanthate, CaO and pine oil. Feed for 1929 averaged 0.58% Cu, tails 0.109%, concentrates 35.05%. Recovery was 81.2%. The cost was 8.65¢ per ton of ore or 1¢ per lb. of Cu. Cupric NH_4 carbonate is the leaching agent. The cuprous salt formed by reaction with the native Cu is oxidized by air in towers. CuO is recovered by distn. and $(NH_4)_2CO_3$ returned to the cycle. Leading costs for 1929 were $23.02 per ton of sand, or 1.83¢ per lb. of Cu. The feed assayed 0.736 and the tails 0.108% Cu with an 85.3% extn.
ALDEN H. EMERY

Milling methods and costs at the Nacozari concentrator of the Phelps Dodge Corporation, Nacozari, Sonora, Mexico. E. H. ROSE AND W. B. CRAMER. Bur. Mines, *Information Circ.* **6358**, 38 pp.(1930).—Chalcopyrite accompanied by min. quantities of chalcocite, covellite and bornite with about 0.05% acid-sol. Cu, chiefly tenorite with some cuprite, is the economic mineral. The ratio of pyrite to chalcopyrite is 2:1. Some sphalerite, magnetite and hematite are present. About ¾ oz. Ag per ton of ore is assocd. with the chalcopyrite. Gang in the upper levels of the mine (20% of output) is hard latite breccia and in the lower levels it is hard andesite breccia. These flows are cut by intrusions of monzonite, diorite and quartz porphyry. Mill heads analyze Cu (total) 2.63, Cu (acid-sol.) 0.05, Fe 11.54, S 8.70, SiO_2 48.58, Al_2O_3 13.70, CaO 1.88, MgO 2.25, ignition loss + material unaccounted for 10.67%. This calcs. to chalcopyrite 7.22, chalcocite and bornite 0.10, tenorite, etc., 0.10, pyrite 11.53 and non-sulfide gang 81.05%. Costs for 1928 and 1929 per ton of dry ore (in cents) were: crushing and conveying 6.15, primary grinding 10.59, secondary grinding 11.70, flotation 10.53, concentrates handline 1.70, tailings 2.76, mill H_2O 1.79, assaying and sampling 1.37, mill dept. expense 4.71 and total 51.30. Pine oil is the frothing reagent; Et xanthate is the collector. The mill recovered 95.86% of the Cu from July to Dec., 1929; tailings assayed: Cu 0.13%, Ag 0.12 oz. and Au 0.001 oz. per ton; concentrates assayed: Cu 23.08%, Ag 5.80 oz. and Au 0.022 oz. per ton. ALDEN H. EMERY

The French aluminum industry. MAX DUVAL. *Bull. Soc. Ind. Rouen* **58**, 264-8 (1930).—A review of the Al industry in France, covering history, methods of production, properties, and uses of Al and its alloys. The latter include aviation, automobiles, elec. work, food and other chem. industries and building. I. H. ODELL

Lithium—the lightest metal. H. S. SPENCE. *Canadian Mining J.* **51**, 994(1930).—An outline of the present situation regarding Li ores in Canada. The Silver Leaf Mining Co. has opened a property about 10 miles northeast of Pointe-du-Bois, where the principal minerals found are lepidolite, spodumene and montebrasic (a variety of amblygonite).
W. H. BOYNTON

Application of light metals in mining construction. E. LOHRKE *Metall u. Erz* **27**, 521-4(1930).—Difficult operating conditions favor the application of light metals in mining machinery and structures. Ventilators, water pumps, safety lamps, pneumatic drills and compressors can advantageously be constructed wholly or in part of such light metal alloys as *silumin* and *lautal*.
H. STOERTZ

Gold, silver, copper, lead and zinc in Arizona in 1928. C. N. GERRY. Bur. Mines, *Mineral Resources of the U. S. 1928*, Pt. I, 761-815(preprint No. 25 published October 15, 1930).
E. H.

The Bannockburn gold discovery. H. C. RICKABY. *Canadian Mining J.* **51**, 1074-5(1930).—The preliminary official rept. describes outcrops and outlines the geological conditions.
W. H. BOYNTON

Occurrence and recovery of finely divided gold. J. TRAUBE. *Metall u. Erz* **27**, 526-7(1930).—Au occurs in a colloidal condition in many minerals. It can be recovered by finely grinding in a colloidal mill followed by flotation. Another method consists in heating at such temp. as will cause aggregation of the fine Au particles. T. has developed a method by which Au can be recovered from colloidal soln. by adsorption on a $BaSO_4$ filter. The red or violet colored $BaSO_4$ so obtained is mixed with glass

powder and heated to about 600°, at which point Au seps. in pieces about the size of pin heads. H. STOERTZ

Tin metallurgy in Great Britain—1929. A. S. FITZPATRICK AND HAROLD S. ELFORD. *Proc. Australasian Inst. Mining Met.* No. 78, 81–161(1930).—A description is given of geology, treatment plants at 9 mines (with flow sheets), ore dressing machinery, roasting practice including As recovery and refining of crude As_2O_3, magnetic sepn., costs of treatment, recovery of SnO from mill waste, flotation in Sn metallurgy, recovery of W, sampling, assaying, sale of Sn concentrates and smelting practice at 2 smelters. ALDEN H. EMERY

The world's resources of tungsten. HARALD CARLBORG. *Jernkontorets Ann.* **114**, 455–90(1930).—The occurrence, uses, consumption, prices, geographical distribution and statistics are discussed. H. C. DUUS

Galician tungsten ores. III. Analysis of Juno, Monte Neme, Casayo and A. Veiga y Vilacoba wolframites. I. PARGO AND AMPARO ARANGO. *Anales soc. españ. fís. quím.* **28**, 905–9(1930).—The chem. compn. of 5 wolframites is shown. A method of analysis of the residue insol. in HCl found in the Corti method is developed, and spectrographic detns. of the Ta_2O_5-Cb_2O_5 residue show it to be only Cb_2O_5. E. M. S.

Swedish iron ore: mining and transport. B. H. STROM. *Eng. Mining J.* **105**, 381–6(1930) W. H. BOYNTON

A process for the extraction of zinc and other metals from ores. H. EDWIN COLEY. *Trans. Inst. Mining and Met.* (London) **37**, 255–65, 265–96(1928).—Active C is considered a far better reducing agent than CO. The advantages claimed for this process which utilizes active C are: continuity of action, small fuel costs, in case of Zn, elimination of retort, complete reduction and almost complete extn. and small power charges. E. I. S.

Flotation of non-sulfidic minerals. G. GERTH. *Metall u. Erz* **27**, 527–9(1930).—Non-sulfidic minerals can be floated by addn. of oleic acid or Na oleate, but to prevent gang materials such as quartz and mica from likewise being floated it is necessary to add Na silicate and an acid or acid salt. Pptn. of the quartz and mica is due to the formation of a silicic acid gel. In an appendix to this article, W. PETERSEN describes the sepn. of oil from sand by flotation, using Na silicate and $FeCl_3$ to hold back the sand particles. H. STOERTZ

Concentration of Swedish iron ores. GUST. G. BRING. *Jernkontorets Ann.* **114**, 64–132(1930).—The concn. referred to is concn. to produce as nearly pure Fe mineral as possible. Magnetite ore can be concd. successfully by magnetic separators and concn. tables. Hematite can be concd. by concn. tables, by flotation or by magnetic roasting. The concn. table causes too great losses. Flotation appears to require extremely fine grinding which adds too much to the expense. Roasting to convert Fe_2O_3 to magnetic Fe_3O_4 was finally resorted to, the reducing agent being air-dried sawdust. It was found that the transformation took place with measurable speed at 300° but the speed increased up to 800°. Cooling of the roast should take place as rapidly as possible for hematite, and might advantageously be done in water since wet grinding is required. Limonites, however, should be cooled slowly in air from 400° to 500°. Photomicrographs indicate that the magnetized roast is a mixt. of Fe_3O_4 and FeO rather than a soln. Large-scale tests using generator gas as fuel showed that a concentrate of over 69% Fe could be obtained. The heat requirements were found to be 10.4% by weight of wood for a 40% ore, of which 30% is present as Fe_2O_3. For charcoal 4.8% by weight is needed. The product is in a very friable condition and easily crushed. Industrial installations have produced a concentrate with 68.32% Fe and a 92.7% recovery. H. C. DUUS

High-velocity hydraulic classification. LEONARD ANDREWS. *Trans. Inst. Mining and Met.* (London) **37**, 406–36(1928). E. I. S.

Core-binders. H. H. EBERT. *Iron and Steel Ind. and Brit. Foundryman* **3**, 363–4 (1930).—A discussion of natural and artificial core-binding materials and their uses are given. C. H. LORIG

Machine control of combustion in metallurgical furnaces of the iron and steel industry. J. F. SHADGEN. *Iron Steel Eng.* **7**, 490–2(1930).—"A survey of the realities and an appreciation of the possibilities." This analysis has mostly the fuel aspect and its relation to greater process economy and plant efficiency. The application of machine control to open-hearth furnaces results in: (1) increase in production; (2) decrease in fuel consumption per ton; (3) longer life of furnace; and (4) better and easier mech. operation. Complete machine control is essential; engineering application is necessary; and service and education of personnel are desirable. W. H. BOYNTON

Technical thermal measurements in cupola furnaces. W. Liesegang and W. Winkhaus. *Die Giesserei* 17, 529–34(1930).—The value for cupola furnace operation and supervision of measuring the amt. and pressure of the blast, and of detg. the compn. and temp. of the throat gases and the temp. of the molten Fe is detd., instruments to be used being discussed. Controlling the amt. and pressure of the blast is necessary, since these det. the coke consumption to a large degree. In agreement with others, it is found that continuous compn. and temp. detns. of the throat gases do not make for a more efficient supervision of the furnace. Measurement of the temp. of the tapped Fe is essential in the operation of furnaces, particularly when these have been newly constructed. J. Balozian

Acid hearth of copper-refining furnace. L. Katterbach. *Metall u. Erz* 27, 525–6 (1930).—Mixing the hearth material, ignition, soaking and handling the first charge are described. H. Stoertz

Furnaces and mills at Apollo Steel Co. A. L. Hollinger. *Blast Furnace & Steel Plant* 18, 1607–10(1930). E. H.

British and Continental open-hearth furnace steel works. H. C. Wood. *Engineering* 130, 373–7, 447–8(1930); *Iron Age* 126, 1299–1302; cf. *C. A.* 24, 5688. E. H.

The optical determination of high metallurgical temperatures—the melting point of iron. C. H. M. Jenkins and Marie L. V. Gayler. *Proc. Roy. Soc.* (London) 129A, 91–114 (1930).—The m. p. of Fe has been detd. by 2 methods. In one, a closed refractory tube is immersed in the center of a mass of metal to serve as a black body enclosure for sighting an optical pyrometer. In the other, a bubble is blown down into a surface of metal. The pyrometer was calibrated by observing the e. m. f. of a Pd thermocouple in a black body enclosure. The m. p. of Pd (1555°) is indicated by the breaking of the metallic circuit, and over a further temp. range by means of the sector method, the m. p. of Au (1063°) being used as the other fixed temp. The m. p. of Fe was found to be 1527° ± 3°. Refractories were made of hard pure alumina. Difficulties were also encountered in that metal vapors penetrated the refractories and emitted radiations to the pyrometer on condensation, but this difficulty was overcome by ventilation with H_2. H. C. Duus

Basic slags from blast furnaces and their utilization for manufacturing cement. P. P. Budnikov and V. M. Lezhoev. *Zhur. Prikladnoĭ Khim.* 3, 669–74(1930).—Properties of unsatisfactory slags are improved by adding $CaSO_4$ to molten slags. V. Kalichevsky

Modern die-casting practice. Ernest V. Pannell. *Engineer* 150, 168–9, 193–4 (1930).—The advantages of various *Zn alloys* are discussed. D. B. Dill

The application of Röntgen rays to steel castings. Herbert R. Isenburger. *Die Giesserei* 17, 893–6(1930).—Descriptive. J. Balozian

The new metal microscope "Seibert-Metallus." B. Blumenthal. *Die Giesserei* 17, 826–9(1930).—A descriptive lecture. J. Balozian

Production of special pig iron and its use in foundries. Paschke. *Metallbörse* 20, 2051–2(1930).—By use of bauxite, limestone and residue-poor ore or scrap in the blast furnace, a special pig iron, with the following av. compn., is obtained: C 4.5–5, Si 0.10–0.30, Mn 0.50, S 0.02 and Al 0.015–0.02%. The metallic Al probably so lowers the CO pressure in the melt that no gas can escape during the solidification. The resulting undercooling capacity permits favorable graphite formation; the structure of the gray special pig iron is purely pearlitic. It is very suitable as added iron in the production of gray iron with very good tenacity; the fluidity of the alloy is uncommonly good and the tendency to funnel formation is minimal. In several foundries the special pig iron has replaced Swedish charcoal pig iron and Indian pig iron. The slag is composed principally of about 7% SiO_2, 40% CaO and 45% Al_2O_3; it is ground and used directly as blast-furnace smelting cement, which is as efficient as elec. furnace cement. Wellington

Long heating periods at high temperatures affect gray cast iron. R. S. Macpherran and H. Krueger. *Foundry* 58, 103–6, 111–2(1930).—Tests conducted by various investigators are cited. The authors detd. the effect of heat on various types of gray cast Fe from 800° to 1100° F., showing changes in combined C, Brinell hardness, tensile and transverse strength. One series was heated to various temps. for 500 hrs. intermittently, while the other was heated continuously. Tests showed tensile strength at elevated temps. The best results were obtained from a series contg. Cr.

The European practice is outlined. Results of investigations are tabulated.
V. S. POLANSKY

X-ray study of some tungsten magnet steel residues. W. A. WOOD. *Phil. Mag.* [7], **10**, 659–67(1930).—The carbides were isolated by dissolving the iron from a no. of steels with analyses averaging W 6, C 0.72, Ni 0.19, Mn 0.28, Si 0.14, S 0.023 and P 0.027%. Photograms showed the presence of W carbide, mixed Fe_4W_2C and a 3rd unidentified compd. No cementite was found. ARTHUR FLEISCHER

Metallographic investigation of vanadium steels. MASAKICHI OYA. *Sci. Repts. Tohôku Imp. Univ.*, 1st Ser., **19**, 331–64(1930).—A systematic investigation of V steels was carried out by means of dilatometric and magnetic analyses, and microscopic observation; an equil. diagram was proposed, from which the following result was deduced: The soly. of C in γ-solid soln. markedly decreases by addn. of V. In the region of γ-phase, 3 primary surfaces exist on which α-phase, Fe_3C and V_4C_3 begin to sep., resp. The A_1 point, that is eutectoid temp. in the Fe–Fe_3C system, is raised by 15° by the addn. of 0.5% V, remaining const. on a further addn. of V; the binary eutectoid reaction ($\gamma \rightleftharpoons \alpha + V_4C_3$) takes place in the temp. range from 745° to about 1330°. A non-variant reaction ($V_4C_3 + \gamma \rightleftharpoons Fe_3C + \alpha$) takes place in the vicinity of the compn. of 0.5% V and 0.9% C. Finally, from the results of the present investigation, several phenomena, which have remained unsolved hitherto, are satisfactorily explained.

Alloy steels for industrial purposes. R. L. DUFF. *Petroleum Mech. Eng.*, Oct. 6–8, 93–7(1930).—The need for accurate data on construction materials is becoming more urgent, especially in the oil industry where increasing temps. and pressures create the necessity for new designs and new alloys and data pertaining to them. The creep of metals and phys. consts. such as the modulus of elasticity, Poissan's ratio, coeffs. of thermal expansion, heretofore but little considered, are becoming increasingly important; the investigation of these at high temps. and pressures presents special difficulties. There is a discussion of some of the work that must be done, some of the research that is now being carried on, together with a description of some of the app. and a few results. WELLINGTON

Cupping test for aluminum sheet. ROBERT J. ANDERSON. *Metal Ind.* (London) **37**, 265–8(1930).—As a measure of drawability, the most reliable and, at the same time the most practical, test is the cupping test. For making the tests, the 2 principal machines used are the Olsen and Erichsen testers. Values obtained in the cupping test depend upon the temper, thickness, compn. and grain size of sheet. The elongation and tensile strength combined influence cupping values. Appearance of the fractured dome of cupping piece is of importance. Results of the test are tabulated.
V. S. POLANSKY

Aluminum—the light metals and their alloys. PAUL MELCHIOR. *Z. Ver. deut. Ing.* **74**, 1267–72(1930).—The properties of the technical "light-metals," *i. e.*, Al, Mg, and their alloys with other metals have been collected and tabulated in the "Aluminum Book" of the author (cf. *C. A.* **23**, 4663). The most important properties for the designer are given, elec. and thermal consts. of the light rolling metals and cast alloys, tensile strength as function of the chem. compn. and pre-treatment, admissible stresses and constructive utilization of the low sp. gr. Most of these properties depend on the purity of the metal and kind of alloy. Rolling metals are: (1) pure Al; (2) refined Al alloys of high tensile strength; (3) refined Al alloys of high elec. cond.; (4) Al alloys of especially high resistance against corrosion; (5) electron. Cast alloys are: (*a*) Al alloys with addns. mainly of Cu, Zn, Si; (*b*) refinable Al-cast alloys; (*c*) electron. Numerical figures of most of the above-mentioned properties are given and tabulated, and fields of application named. All light metals, even if containing iron in comparatively high amounts, are non-magnetizable. M. HARTENHEIM

Aluminum alloys for aircraft-engine piston and cylinder heads. A. J. LYON. *Aeronautical Eng.* (*A. S. M. E. Trans.*) **2**, 257–69(1930).—See *C. A.* **24**, 3743.
E. C. K.

Nature of eutectoid transformation of aluminum-bronze. II. Effect of quenching velocity. ICHIJI OBINATA. *Mem. Ryojun Coll. Eng.* **3**, No. 2 B, 87–94 (reprint) (1930); cf. *C. A.* **24**, 1068.—An evolution of heat between 500° and 400° on water quenching is due to the transformation $\beta \longrightarrow \beta'$; the resulting acicular structure is an intermediate structure of this change. The homogeneous structure resulting from cooled-toluene quenching is a single solid soln. of the β-phase. Upon cooling the alloy at a certain velocity less than water quenching, the acicular pattern disappears and an apparently homogeneous structure, regarded as the β'-phase and having the max. Brinell hardness value, appears; the segregation of the α-phase occurs independently of the martensitic needles. WELLINGTON

Artificial aging of duralumin and superduralumin. K. L. MEISSNER. *Engineering* **130**, 473–5(1930).—See *C. A.* **24**, 5268. E. C. K.

Magnetic properties of permalloy with internal strains, and their influence through stretching and compression. OTTO VON AUWERS. *Wiss. Veröffentlich. Siemens-Konzern* **9**, 262–93(1930).—The magnetic properties of compound wires, consisting of a permalloy sheath surrounding a central core, were studied after drawing both before and after heat treatment. By proper choice of core material, the permalloy sheath was subjected to various internal strains, while the corresponding external stresses were applied by stretching or the use of hydraulic pressure. The effects of these stresses upon the magnetic properties are shown by a no. of tables and curves exhibiting the influence of stretching and compression on the initial magnetization curve, the μ-curve, max. permeability, remanence, coercive force and position of the hysteresis loops. Under the influence of stretching the hysteresis loops seem to be tipped to a definite axis passing through the origin as if there were 2 fixed points on the increasing and decreasing branches, the coördinates of which are independent of the load. Pressure in general affects only coercive force and produces an effect opposite to that produced by stretching. The effects on hysteresis of regulated stresses seem to be the same as those produced by unregulated stresses (*e. g.*, those due to impurities or working) but this is not the case with remanence and coercive force.
W. W. STIFLER

The evaluation of Röntgen film densograms by cross-sectional diascopy of metals and alloys. WILLI CLAUS. *Die Giesserei* **17**, 745–9(1930).—The method of obtaining densometric curves from the röntgenograms of cast metals and alloys is briefly described, and is applied to studying the structure of the GBz 10 of C. and Goeke (*C. A.* **23**, 5143). These investigations show that densometry may be advantageously employed in metal foundries. Densograms (10) of sections of the cast bronze alloy GBz 10 with the corresponding röntgenogram positives are shown. J. BALOZIAN

X-ray study of the constitution of some copper-nickel-aluminum-manganese alloys. LYMAN J. WOOD. *J. Am. Chem. Soc.* **52**, 3833–8(1930).—Methods and app. used are described and results tabulated. Both the photomicrographs and x-ray patterns show that these alloys are in the main α-solid solns. Some evidence for a second constituent is presented but complete identification has not yet been made. V. S. POLANSKY

The shrinkage of metals and alloys. F. SAUERWALD *Die Giesserei* **17**, 793–5(1930).—Expts. are made to det. if the shrinkage nos. of metal or alloy castings are related to their coeffs. of expansion or to various other influences during the pouring and solidification. The castings are made in a V-shaped quartz ladle, thereby eliminating these influences and allowing the choice of any gas atm. or cooling velocity. The results of these and previous investigations (Sauerwald, *C. A.* **23**, 5455) of pure metals belonging to the regular crystal system show that the shrinkage nos. may be calcd. with exactness from the neg. coeffs. of expansion (if the influence of gases is excluded)
J. BALOZIAN

The shrinkage of copper-tin alloys. F. BOEHM AND F. SAUERWALD. *Die Giesserei* **17**, 841–9(1930).—The shrinkage of various Cu-Sn alloys (contg. 40%, 38.36% (Cu_3Sn), 31.82% (Cu_4Sn), 10, 5, 4, 2.5% Sn) is detd., the specimens being fused and solidified in a quartz ladle in either an A or H_2 atm. The thermal effects are studied by use of the Cu-Sn equil. diagram of Bauer and Vollenbruch (*C. A.* **18**, 2676). The av. values of the total shrinkages of the alloys are: 40% Sn = 2.38%, 38.36% Sn = 2.53%, 31.82% Sn = 2.02%, 10% Sn = 1.28%, 5% Sn = 1.56%, 4% Sn = 1.77%, and 2.5% Sn = 1.82%. The total shrinkage may be calcd. from the coeff. of expansion for small temp. differences. In general, the shrinkage curves of the alloys are horizontal until solidification is complete and then drop suddenly (indicating that shrinkage is taking place). However, when solidified in a H_2 atm., alloys in the α-mixed crystal field show a strong expansion after the horizontal followed by shrinkage, but if solidified in an A atm. these show a shrinkage after the horizontal followed by an expansion and finally by shrinkage. The expansion is proportional to the liquidus interval and decreases with the Sn content of the alloy. J. BALOZIAN

The influence of nickel on the temperatures of the metastable and stable A_1-transformation of eutectic iron-carbon and iron-carbon-silicon alloys. The graphite eutectoid. A. MERZ AND F. FLEISCHER. *Die Giesserei* **17**, 817–25(1930).—Since the results in the literature are not in agreement, the influence of Ni (0–3%) on the metastable and stable A_1-transformation (I) temps. of Fe-C and Fe-C-Si (contg. up to 3% Si) alloys is investigated for the velocity 0°/min. The metastable I temp. decreases linearly with increasing Ni content (12°/1% Ni) and is increased initially by Si, this increase becoming progressively smaller with increase in Si. The lowering of the temp.

of Ac_1 by Ni is less than that of Ar_1, while the increase in Ac_1 on addn. of Si is greater than that in Ar_1. This hysteresis increases with increasing Ni and Si contents of the alloys, being smallest in those contg. Ni alone. The stable I temp. is increased linearly with increase in Si (31°/1% Si), and is linearly decreased with increase in Ni (12°/1% Ni). The metastable and stable I temp. surfaces in dependency on the Ni and Si contents are continuous, the former lying below the latter. The existence of the graphite eutectoid is affirmed. Micrographs (4) are given. J. BALOZIAN

Silicon-copper alloys and silicon-manganese-copper alloys. E. VOCE. *Engineering* **130**, 441–3(1930).—See *C. A.* **24**, 5270. E. C. K.

New silicon-zinc-copper alloy. E. VADERS. *Metal Ind.* (London) **37**, 315–8, 465–8(1930).—See *C. A.* **24**, 5270. E. C. K.

Equilibrium diagram of the lead–tin system. KOTARO HONDA AND HITISABURO ABE. *Sci. Repts. Tohôku Imp. Univ.*, 1st Ser., **19**, 315–30(1930).—The equil. diagram of the Pb–Sn system has been studied by differential thermal analysis. It was confirmed that the heat evolution occurring at about 160° just below the eutectic point is due to a rapid decrease in soly. of the β-phase in the α solid soln., with the fall of temp. Thus the equil. diagram of the system was greatly simplified by omitting a horizontal line at about 160°.

Change of electric resistance produced in cold-worked metals by annealing. *Sci. Repts. Tohôku Imp. Univ.*, 1st Ser., **19**, 265–82(1930).—The elec. resistance of cold-worked metals decreases as the result of annealing them in a vacuum at comparatively low temps., but this resistance is generally increased by annealing them at higher temps. It has also been found that the resistance of Cu is considerably increased by the occlusion of H gas. An explanation of these changes of elec. resistance of metals caused by cold-working and annealing is given.

Effect of hydrogen sulfide on wire rope. L. W. VOLLMER AND B. B. WESTCOTT. *Petroleum Mech. Eng.* Oct. 6–8, 57–61(1930).—Mol. H cannot induce brittleness in steel. At. or nascent H ($H_2S + Fe \longrightarrow FeS + 2H$), absorbed by the intercryst. material, rapidly causes embrittlement. The effect is largely a surface reaction. A method was devised for detg. degree of embrittlement. Cold-drawn plain C steel wires did not become embrittled when treated with perfectly dry H_2S or immersed in water-free crude oil satd. with H_2S, but rapidly became brittle when treated with moist H_2S or immersed in oil-well brine satd. with H_2S; the degree of embrittlement is proportional to the amt. of cold work and has no relation to the C content while in dead-soft annealed plain C steels the degree of embrittlement is inversely proportional to the C content. Steel wire embrittled by H_2S recovers most of its original ductility after standing for a time or by gentle baking for several hrs. Embrittlement may be prevented by a coating that prohibits the contact of the H_2S with the steel. Zn, Pb and Cu offer excellent protection; Sn is worthless. WELLINGTON

The nature of corrosion and its measurement. G. DORFMÜLLER. *Deut. Zuckerind.* **55**, 981–2(1930).—A discussion. J. F. LEETE

A new method for quickly testing the corrosion of different metals simultaneously. G. GOLLNOW. *Die Giesserei* **17**, 665(1930).—The app. of Tödt (*Chem.-Ztg.* **29**, 567), manufd. by Ströhlein & Co., Braunschweig, Wolfenbütteler Str. 41, for electrically measuring the corrosion of metals in corrosive liquids is briefly described and directions for its use are given. J. BALOZIAN

Purely chemical methods for prevention of corrosion of metals. JEAN COURNOT AND JEAN BARY. *Rev. metal.* **27**, 479–85(1930).—A brief survey of the methods of coating metals including bronzing of steel and parkerization, giving some results of corrosion tests in the salt spray on the latter. Mention is made of a new process somewhat similar to parkerization invented by Boulanger and giving remarkable protection. J. D. GAT

Effect of contamination by nitrogen on the structure of electric welds. L. W. SCHUSTER. *J. Iron Steel Inst.* (London) advance copy, Sept., 1930, No. 8, 30 pp.—A bibliography of 50 references is given. Microscopic examn. of arc welds made from various rods and in amts. of air, CO_2, O, N and H have shown that the needles found in welds are caused by N. Needles never occur in the absence of N. A heat treatment is frequently necessary to develop the needles. Typical photomicrographs are shown. Also in *Engineering* **130**, 538–40 (1930). J. L. GREGG

Silver solders. R. H. LEACH. *Metal Ind.* (London) **37**, 337–40, 369–71(1930).—See *C. A.* **24**, 4498. E. C. K.

Physicochemical analysis of *Eucalyptus globulus* essential oil [as flotation agent] (BATUECAS, MORALES) 17. Chemical characteristics of cement pipe lining (Chappell)

20. Influence of annealing atmosphere, annealing temperature and protecting tube material upon the stability of Pt thermoelements (STÄBLEIN, HINNÜBER) **1.**

GRARD, C., and COURNOT, J.: Metals and Alloys. Paris. Berger-Levrault. 3 Vols. F. 110. Reviewed in *Bull. Soc. Ind. de Mulhouse*, **96**, 549.

Rotatable ball mill for crushing ores, etc. HARLOWE HARDINGE (to Hardinge Co.). U. S. 1,780,915, Nov. 11. Structural features.

Ore-flotation concentration. ELMER K. BOLTON (to E. I. du Pont de Nemours & Co.). U. S. 1,780,000, Oct. 28. A mercaptothiazole such as 1-mercapto-3-methylbenzothiazole is used with frothing agents to facilitate concn. of Cu ores, etc.

Flotation concentration of phosphate-bearing material. JOHN W. LITTLEFORD (to Minerals Separation North American Corp.). U. S. 1,780,022, Oct. 28. A pulp of the material relatively free from slimes is mixed with alkali such as NaOH and afterward mixed with a float-assisting substance such as oleic acid and fuel oil and agitated to produce a float concentrate and the latter is sepd. An arrangement of app. is described.

Selective agent for concentration of ore by flotation. ROYER LUCKENBACH. U. S. 1,780,024, Oct. 28. A heavy asphalt base petroleum oil 7 is mixed with horse grease oil 1–2 parts.

Liquid supersaturated solution of thiocarbanilide. PHILIPP SIEDLER and AUGUST MOELLER (to I. G. Farbenind. A.-G.). U. S. 1,780,634, Nov. 4. A compn. which is suitable for use as a froth-flotation agent comprises a supersatd. soln. of thiocarbanilide in "technically pure" toluidine together with 0.3–20% of resin such as colophony.

Separating metal compounds from ores such as those of copper, iron and zinc. OSCAR A. FISCHER. U. S. 1,779,841, Oct. 28. Ores such as sulfide ores of Cu, Fe and Zn contg. As or Sb are subjected to a sulfatizing roast and to selective reduction by temp. control below 800° in the presence of a reducing agent to form insol. products from some of the sulfates, such as those of Cu and Fe, in the absence of substantial quantities of SO_3, while other sulfates remain unchanged, and the sol. sulfates such as $ZnSO_4$ are then leached out.

Reducing iron ores. FREDERICK L. DUFFIELD. U. S. 1,779,411, Oct. 28. A charge of ore and carbon is introduced into a reducing chamber at the base of the chamber and is raised through progressively hotter zones inside the chamber; gases evolved in the reducing chamber are collected at its top and are burned in admixture with air in a sep. combustion chamber at the side of the reducing chamber, the direction of movement of the burning gases being opposite to the movement of the ore charge. App. is described.

Iron ore reduction, etc. N. AHLMANN. Brit. 332,226, April 16, 1929. In promoting reduction of iron ore or other operations of chem. reaction, drying, etc., involving heating or cooling of pulverulent or granular materials, the material, in a filled chamber, is stirred with hollow stirring arms through which a heating or cooling medium may be circulated and air or a suitable gas is introduced at low pressure at the bottom of the chamber to facilitate stirring. App. is described.

Extracting tin from ores, etc. EDGAR A. ASHCROFT. U. S. 1,780,106, Oct. 28. A mass of Sn-bearing material such as Cornish "lode tin" ore is mixed with a carrying salt such as $ZnCl_2$ and a collecting metal such as Ni and the materials are heated to form an alloy of Sn with the collecting metal. Various modifications of the process are described.

Vanadium recovery from ores, etc. BYRAMJI D. SAKLATWALLA (to Vanadium Corp. of America). U. S. 1,779,856, Oct. 28. An aq. pulp of material such as sulfidic V-bearing ore or residue is subjected to the action of a Cl-contg. gas such as Cl or S chloride which produces oxygenating Cl compds. in contact with water, in order to form sol. V compds.

Treating zinciferous material containing lead or cadmium. LLOYD E. TEITER (to New Jersey Zinc Co.). U. S. 1,779,862, Oct. 28. Material such as roasted Zn concentrates contg. Pb or Cd or both is sintered by blast roasting in the presence of a chloridizing agent so that a substantial amount of Pb and Cd or both segregates near the blast-exiting surface, and this surface portion is sepd. from the remainder of the sintered product. App. is described

Rotary ore-roasting apparatus. GEORGE E. STORER (to National Processes, Ltd.). U. S. 1,778,872, Oct. 21. Various details are described of an app. arranged for sep. collection of gases from different stages of the operation.

Blast-furnace tuyère. E. H. HOLZWORTH. Brit. 331,464, Oct. 30, 1929.

Blast-furnace operation. JOHN C. HOPKINS and ALFRED OSOLIN. U. S. 1,780,485, Nov. 4. The furnace is tapped with the blast pressure on and the flow of iron is then stopped while the blast pressure is maintained by forcing a continuous and uninterrupted flow of clay into the tapping hole under sufficient pressure to stop the flow of the iron and completely plug the tapping hole. Structural details are described.

Furnace and associated apparatus for heat treatment of minerals, etc., in containers which are passed through the heating chamber. J. E. HACKFORD. Brit. 331,259, Dec. 21, 1928. Structural features.

Furnace with a pivotally mounted tilting hearth, suitable for heating small metal articles for hardening. RICHARD KAIER (to Singer Mfg. Co.). U. S. 1,779,435, Oct. 28. Structural features.

Furnace heating for metal sheets in packs, etc. HENRY A. DREFFEIN (to Flinn & Dreffein Co.). U. S. 1,779,964, Oct. 28.

Treating furnace dust. WM. J. MCGURTY (to Bartlett Hayward Co.). U. S. 1,780,833, Nov. 4. Dust-carrying gases such as blast-furnace gases are discharged into a dust collector where at least a portion of the solids is arrested and the gas is then washed, solids recovered are dewatered and these solids are mixed with those arrested in the dust collector and the mass is dried and roasted, sintered and returned to the furnace.

Ingot mold. AXEL G. E. HULTGREN. U. S. 1,781,392, Nov. 11. A mold with a downwardly tapered casting cavity has a depressible bottom adapted to allow sinking of the ingot after initial peripheral congealing has occurred, thus maintaining contact between the ingot and the mold. Various structural details are described.

Casting electric heater plates from molten metal. LON MCKINNEY (to Griswold Mfg. Co.). U. S. 1,778,808, Oct. 21. Various mech. details are described.

Malleable iron castings. LESLIE H. MARSHALL (one-half to Adin A. Grubb). U. S. 1,781,119, Nov. 11. White iron castings are subjected to heat treatment to effect malleableization and while the temp. is above 540° a non-oxidizing and etching gaseous atm. such as one contg. chloride vapors is maintained around the castings.

Dental castings. F. S. MEYER. Brit. 332,194, April 9, 1929. To compensate for contraction during solidification of Au castings such as crowns and inlays, the plaster mold is made of a harder plaster than usual and at an elevated temp. so that the wax pattern is expanded. A fluid plaster mixt. may be used contg. a large proportion of silica, at a temp. of about 50°. Various details of procedure are described.

Casting and rolling copper. WM. F. EPPENSTEINER and HENRY M. GREEN (to American Metal Co., Ltd.). U. S. 1,779,534, Oct. 28. Cu is cast into elongated cakes by pouring into a parallel-sided upright open-topped mold provided with a water jacket which causes chilling of the cast metal and shrinking to free it from the mold walls; the cake is removed, and has an oxidized portion substantially confined to its top end, and it is rolled endwise to a thin elongated form and the oxidized end is cropped off.

Rolling metals. AMERICAN ROLLING MILL CO. Brit. 332,462, Jan. 8, 1929. In forming sheets, the metal is hot rolled with substantial reduction, cold rolled without removal of scale, annealed and pickled and then rolled to gage. Various details of app. and procedure are described.

Rolling wide thin pieces of metal. W. STRINGHAM. Brit. 331,448, Sept. 30, 1929. Various details of rolling are described.

Rolling thin material such as steel strips. ABRAM P. STECKEL (to Cold Metal Process Co.). U. S. 1,779,195, Oct. 21. In operating a mill with working rolls, and backing rolls of larger diam. for the working rolls, rise in temp. of the backing rolls is sufficiently limited to prevent change of their contour which would permit buckling or wrinkling of the thin material passed between the working rolls. App. is described. Cf. *C. A.* **24**, 1337.

Refining copper. AMERICAN METAL CO., LTD. Brit. 331,353, June 7, 1929. Copper ingots to be melted and refined are preheated to a temp. somewhat below the m. p. and are plunged separately into a bath of metal in the melting furnace. The metal, in superheated state, is discharged from the melting furnace to a tilting refining chamber in which it is covered by a layer of deoxidizing slag and a layer of carbon. Oxide from the metal passes to the slag and the latter may be maintained in an active state either chemically by the carbon layer or electrolytically. Various details of app. and procedure are described.

Refining zinc. FRANK R. KEMMER (to American Cyanamid Co.). U. S. 1,779,973, Oct. 28. Raw Zn is placed in a liquating furnace, the temp. of which is raised to a point materially above the m. p. of Zn, causing the molten mass to sep. into at least 2 layers,

the upper layer being spelter contg. the major portion of the precious metals, and the next layer being hard Zn contg. only a minor portion of the precious metals; the spelter is distd. to volatilize and recover refined Zn, and the precious metals are recovered as a residue. App. is described.

Metallic grit from molten iron. DAVID MARTIN (to Globe Steel Abrasive Co.). U. S. 1,780,201, Nov. 4 Streams of molten iron are introduced between closely spaced opposed parallel surfaces of rotating rolls in the presence of a cooling liquid such as water carried peripherally on the rolls, the streams are flattened and the flattened molten iron is broken up by the combined effects of mol. cohesion of the metal and the conversion into steam of portions of the water in engagement with the flattened surfaces. Various details of app. are described.

Pig iron. M. NEUMARK. Brit. 331,190, March 22, 1929. A pig iron with properties of charcoal iron is obtained by melting down, in a coke blast furnace, scrap alone or in admixture with ore and a flux mixt. proportioned to produce a slag contg. at least 30% alumina and below 10% silica. Bauxite may be added to supply the alumina.

Steel or iron from cast iron. GASPARD JAKOVA-MERTURI (to Société générale d'exploitation des carbones). U. S. 1,779,744, Oct. 28. A fibrous carbonaceous material such as wood is heated to a point short of complete decompn., the resulting product is impregnated with salt such as $NaNO_3$ and the impregnated material is pulverized and injected upon the cast iron as the latter comes from a blast furnace, to effect its desulfurization and dephosphorization.

Heat-treating steel. HORACE C. KNERR. U. S. 1,779,604, Oct. 28. The metal is passed through a heating zone to raise its temp., its progress being retarded by the action on it of a magnetic field through which it passes until it reaches a temp. at which it becomes non-magnetic, and the time when cooling occurs is controlled by the time the metal becomes non-magnetic, as by release from magnetic force. App. is described.

Alloys for electrical contacts. EDWIN F. KINGSBURY (to Western Elec. Co.). U. S. 1,779,602, Oct. 28. Pd is alloyed with Cu (suitably about 40%). U. S. 1,779,603 specifies Pd alloyed with W. Ni and other metals also may be present.

Alloys such as alloy steels. PERCY A. E. ARMSTRONG. U. S. 1,781,490, Nov. 11 In effecting the melting of metals in a metallic crucible such as one formed of Cu having a lower m. p. than the temp. to which the melted metal is raised, metallic ingredients such as those for an alloy steel, intermixed with slag-forming ingredients, are exposed to the heat of an elec. arc initiated near the bottom of the crucible, while permitting heat to dissipate from the walls of the crucible, so that a progressive slag lining for the crucible is formed as the volume of molten metal increases. App. is described.

Lead alloy containing antimony and bismuth. MARTIN THIELERS. U. S. 1,779,784, Oct. 28. An alloy which is suitable for sheathing cables comprises Pb about 98-99 and Sb about 1% together with a small quantity of Bi (suitably about 0.5%).

Hardening lead alloys. MICHAEL G. CORSON. U. S. 1,780,261, Nov. 4. An alloy formed mainly of Pb and contg. also 0.5–15% each of Sb and Cd is heated to above 200° but below the m. p. for a sufficient time to bring the Sb and Cd into solid soln. in the Pb matrix, followed by cooling to produce supersatn. and then by aging.

Iron alloy containing copper, silicon and aluminum. BYRAMJI D. SAKLATWALLA. U. S. 1,781,527, Nov. 11. An alloy resistant to corrosion and scaling at high temps. and which is suitable for engine valves, elec. resistance heaters, etc., comprises Fe together with Cu 0.5–5.0, Si 0.5–6.0 and Al 0.1–2.0%, together with C within the range present in cast iron.

Acid-resisting iron alloys. K. M. TIGERSCHIÖLD. Brit. 331,414, Aug. 2, 1929. Alloys are described contg. Fe together with Ni 15–30, Cr up to 3, C 0.05–1.5, Si 2.5–10 and Cu 0.2–25% (the Si being wholly or partly replaceable by Mo and the Ni by Co). Small proportions of V, Ti, W and Mn also may be present, and when the alloy contains Mo (suitably 0.2–10%) the Si and Mo together preferably exceed 10%.

Steel alloy. LINWOOD M. BROWN. U. S. reissue 17,846, Oct. 28. See original pat. No. 1,643,054 (*C. A.* **21**, 3596).

Zinc alloys for die casting. EDMUND A. ANDERSON (to New Jersey Zinc Co.). U. S. 1,779,525, Oct. 28. Zn is alloyed with Al 2–5 and Mg 0.01–0.3%.

Melting zinc alloys or other metals in a rotary furnace. C. BRACKELSBERG. Brit. 331,791, Aug. 20, 1929. The metal is melted by contact with the walls of a rotary furnace which is heated up before insertion of the charge. Various details of a furnace construction are described.

Apparatus for hardening the bearing parts of shafts by heating and quenching. F. KLOPP. Brit. 331,484, Feb. 25, 1929. Structural features.

Chromium- or chromium-alloy-plating of paper-making apparatus. J. STRACHAN and R. MARX. Brit. 331,196, Jan. 18, 1929. Wire fabric is plated with Cr or its alloys such as those with Ti, Mo or W. Various details are given.

Silicon steel sheets for electrical purposes. A. F. MURPHY and W. JONES. Brit. 331,511, April 2, 1929. The sheets are pickled, freed of acid, annealed, cold-rolled, and re-annealed in a process, various details of which are described.

Pickling metals. LUDWIG J. CHRISTMANN (to American Cyanamid Co.). U. S. 1,779,961, Oct. 28. A pickling bath for metals such as iron or steel sheets contains H_2SO_4 together with a small proportion of a condensation product of aldehyde-NH_3 and monophenyl thiourea, which serves as an inhibitor. Cf. *C. A.* **24**, 330.

Pickling and cleaning metals. RALPH E. LAWRENCE (to Grasselli Chem. Co.). U. S. 1,780,594, Nov. 4. An acid bath such as a soln. of H_2SO_4 for pickling steel sheets is used with an inhibitor such as thioglycolic acid or its derivs. contg. the radical $COOH\text{-}CH_2\text{-}S$. U. S. 1,780,595 relates to the use of a mustard oil as an inhibitor. Cf. *C. A.* **24**, 5015.

Pickling iron and steel. JAMES C. VIGNOS (to Rubber Service Laboratories Co.). U. S. 1,779,787, Oct. 28. A soln. of H_2SO_4 is used which contains a small proportion of sulfonated creosote oil which serves as an inhibitor.

Utilizing galvanizer's waste. WM. G. WARING. U. S 1,780,323, Nov. 4. Metallic particles are screened out from the wet ground waste, the screened slurry is neutralized (suitably with $Ca(OH)_2$), NH_3 is distd. off, ferrous iron is oxidized to ferric condition (suitably by an air current) and the slurry is filtered and the solids are washed to remove chlorides, and the washed solids are extd. with $(NH_4)_2CO_3$ soln. to dissolve and remove Zn while leaving Pb compds. undissolved.

Preventing corrosion of tin plate kettles. W. M. SIMPSON. Brit. 331,649, May 22, 1929. One or more strips of Zn are soldered to the base of the kettle.

Preventing incrustation and corrosion of heating and cooling apparatus. H. GROECK (to Groeck Wasserveredlung-Ges.). Brit. 331,725, Nov. 14, 1928. In app. in which no substantial evapn. of water occurs, incrustation and corrosion are prevented by adding chromic acid or a dichromate to the water.

Welding flux. W. REUSS. Brit. 332,048, Nov. 1, 1928. To a flux such as described in Brit. 296,923 (*C. A.* **23**, 2416) is also added NH_4Cl, NaCl and H_2SO_4 or HCl. Alkali metal sulfates or nitrates also may be used instead of part or all the NaCl.

Electric flash welding of metals. WARREN F. HEINEMAN (to A. O. Smith Corp.). U. S 1,780,297, Nov. 4. Mech. and elec. features.

Electric welding of tubes of different metals such as copper and iron. GEORG KALSCHNE (to General Elec. Co.). U. S. 1,779,278, Oct. 21. Various mech. and elec. details are described, relative to welding abutting ends of tubes.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

An appreciation of the life and work of Prof. W. H. Perkin. W. N. HAWORTH. *Chemistry and Industry* **49**, 886–9(1930). E. H.

The discovery of synthetic alizarin. LOUIS F. FIESER. *J. Chem. Education* **7**, 2609–33(1930). E. H.

Synthesis of some higher isoparaffins. S. LANDA AND R. RIEDL. *Collection Czechoslov. Chem. Comm.* **2**, 520–30(1930).—$Me(CH_2)_{14}CHMe_2$ (I) and $Me(CH_2)_{28}CHMe_2$ (II) have been prepd. by the following series of reactions. The ester with 2 less C atoms with MeMgBr gives the alc. which on distn. yields 2 olefins which by hydrogenation give the paraffin. $Me(CH_2)_{14}CMe_2OH$ was made from Et palmitate, a 20% excess of MeMgBr being used. Yield 90%. The alc. is dehydrated by distn. at 100 mm. 2-Methyl-2-heptadecene, m. —2.5°, b. 314°, d_{20} 0.7953, is the only product as proved by oxidation. The di-Br deriv. b_{28} 267–8°. Hydrogenation was carried out at 220–40° for 82 hrs. The unchanged olefin was brominated and the 2 products sepd. by distn. Yield 25%. Rape oil was hydrogenated, using 2% Ni at 120 atm. The solid product is sapond. with twice the theoretical amt. of alc. KOH and the acid freed by dil. H_2SO_4. After heating to 125° the acid is dissolved in alc., HCl gas passed in, water is added and the product heated to 135°. Distn. at 15 mm. and 252–8°, recrystn. from alc. and a 2nd distn. at 255° yields 20% Et behenate, m. 48.5°. Treatment with twice the theoretical amt. of MeMgBr, distn. at 0.002 mm., and crystn. from Et_2O yields 90% $Me(CH_2)_{20}CMe_2OH$, m. 63°. Distn. of the alc. at 290° and

100 mm. yields $Me(CH_2)_{10}CH:CMe_2$, m. 41.5, b_{10} 234–7°. Hydrogenation, carried out at 180° and 1 atm., is incomplete and the product is obtained by twice pptg. an Et_2O soln. with 0.5 its vol. of alc. The product has I no. 1.2, m. 42°, d. 0.7882 at the m. p. V. F. HARRINGTON

Aluminum chloride in organic chemistry. G. KRÄNZLEIN. *Metallbörse* **20**, 1856–7 (1930).—The scientific and com. importance of anhyd. $AlCl_3$ in the Friedel-Crafts reaction, the Fries displacement, the Scholl dehydration and addn. reactions, condensation with H_2O splitting off, halogen transfer, introduction of NO_2 groups, polymerization and condensation, splitting and rearrangement, and cracking processes as well as hydrocarbon and Gattermann-Koch aldehyde syntheses are reviewed. Various possibilities of prepn. of aromatic CO_2H acids are pointed out. The prepn. of ketones and the importance of *o*-benzoylbenzoic acids are discussed. The use of $AlCl_3$ for ring closure is explained, *e. g.*, oxythionaphthene, acenaphthenone, condensations with $(COCl)_2$ give open and closed ring ketones. Many isatin syntheses can be made with $AlCl_3$. Coupling of other than C atoms with aromatic nuclei is mentioned. Data on the Fries displacement are explained on the basis of the most recent results. Advances made in the Scholl reaction are shown, pointing out the necessity of removal of split off H by an oxidizing agent. Among the dehydration reactions flavanthrene and 2,5-diphenylbenzoquinone are mentioned. In addn. reactions there is shown the favorable effect of $AlCl_3$ in causing H_2O to split off and halogen or NO_2 groups to enter the ring more easily. E. M. SYMMES

Polymerization reactions of ethylene. H. M. STANLEY. *J. Soc. Chem. Ind.* **49**, 349–54T(1930).—A review of chem. and patent literature on the polymerization of C_2H_4. S. believes that the action of $AlCl_3$ on C_2H_4 can be explained by (1) polymerization to higher olefins, (2) isomerization of the latter to produce the corresponding cycloparaffins, and (3) the splitting off of lower paraffin mols. with the simultaneous production of hydrocarbons of lower H content. Reactions 1 and 2 take place at lower temps. Reaction 3 requires a higher temp. L. F. AUDRIETH

Autoxidation of the amylenes. JULIUS HYMAN AND C. R. WAGNER. *J. Am. Chem. Soc.* **52**, 4345–9(1930).—$PrCH:CH_2$ and $EtMeC:CH_2$ show no reaction with O in the dark at 15° with Co oleate as oxidation catalyst. Iso-$PrCH:CH_2$, $EtCH:CHMe$ and $Me_2C:CHMe$ react, the first compd. showing a long induction period; all 3 show about the same order of activity, the reaction being followed by titration of the bound O by I; after 156 hrs. the cc. of 0.01 *N* $Na_2S_2O_3$ used by the 3 hydrocarbons are: 22.15, 18.00, 19.75. The results indicate that, in general, internal double bonds are more readily oxidized by mol. O than end double bonds. In the prepn. of $PrCH:CH_2$ by Kirrmann's method, there is obtained a fraction b. 20–4°, probably ethylcyclopropane. The results appear to bear little or no relationship to the results of the H_2SO_4 polymerization expts. of Norris and Joubert (*C. A.* **21**, 1444). C. J. WEST

The structure of acetylene on the basis of spectroscopic investigations. R. MECKE AND K. HEDFELD. *Z. Elektrochem.* **36**, 803(1930).—The absorption spectrum for the region 9000–7000λ shows 3 bands of identical structure at 7887, 7956 and 8623λ. These measurements show that C_2H_2 has an extended ("gestreckte") structure with 1 moment of inertia. Five frequencies were found, in agreement with the calcd. values: 730, 1330, 1970 (inactive), 3280 and 3320 (inactive). Intensity measurements indicate a 1:3 interval, exactly as in H_2, suggesting that C_2H_2 should exist in 2 modifications. J. H. REEDY

Pyrolysis of allene and methylacetylene. RICHARD N. MEINERT AND CHARLES D. HURD. *J. Am. Chem. Soc.* **52**, 4540–7(1930).—Results are given for the pyrolysis of allene (I) at 400–600°; a temp. of 500° is best for the formation of liquids by the flow method; at this temp. and with a contact time of 86 sec., 80% of the I entering the reaction tube was consumed and 90% of the products appeared as liquids. At 600° with a contact time of 50 sec., only 43% of the non-recoverable I appeared as liquids. At 500° 1 cc. of gas (mixt. of C_2H_2, C_2H_4, H and paraffins) was formed from each 10 cc. of I. CH_4 represented the large part at 500° but at 600° the vols. of CH_4 and H were almost equal. The following liquid fractions were obtained from the liquids formed at 500°: b. 63–6°, n_D^{20} 1.4358, sharp, irritating odor; b_{10} 35–50°, n_D^{20} 1.5002, turpentine odor; b_{10} 71–80°, n_D^{20} 1.5142, turpentine odor; b_{10} 80–105°, n_D^{20} 1.5617, kerosene odor; b_8 105–155°, n_D^{20} 1.596; b_{10} 160–90°, n_D^{20} 1.63, very viscous, odor of burnt rubber. The low-boiling fractions are very nearly identical with Lebedev's dimer and α-tetramer (*C. A.* **9**, 798). MeC : CH, for which a method of prepn. from Na acetylide and Me_2SO_4 is given, first isomerizes to I, which then polymerises in its customary manner. The relationship of CH : CMe to the 3-C system has been

developed and the classification of I and CH : CMe as of the keteno-ynol type has been suggested because of its similarity to the keto-enol type. C. J. WEST

Dichloroacetylene. ERWIN OTT, WALTER OTTMEYER AND KURT PACKENDORFF. *Ber.* 63B, 1941–4(1930).—ClC : CCl (I) can be obtained in 65% yield by passing the vapors of $Cl_2C:CHCl$ at 130° over solid granulated KOH previously dehydrated until it solidifies about 200°. If all local superheating is avoided by using an elec. oven, the prepn., contrary to Ottemeyer's observations (*Diss. Münster*, 1926), is without danger. Pure I is a mobile liquid with the same disagreeable odor as the di-I compd. When it issues through H_2O into the air it at once ignites and burns with deposition of much soot, but if it is strongly dild. with CO_2 or N it forms in the air white smoke rings and a distinct $COCl_2$-like odor is perceptible. If a vessel filled with the vapor is opened, a violent explosion occurs. Such explosions are also brought about by slight superheating above the optimum temp. (130°) for its formation. In dil. Et_2O solns. (5–10 wt. %), autoxidation even by O is very slow, but solns. in $(CHCl_2)_2$ react instantly with air or O with formation of a mist and a hissing sound as when H_2O is dropped into hot fat. The autoxidation gives chiefly $COCl_2$, CO and CO_2. No $(COCl)_2$ could be detected with certainty. The addn. of halogens points strongly against an acetylidene structure for I. Br is added in dil. CCl_4 soln. as vigorously as O, forming a product identical with that obtained by bromination of ClCH:CHCl. I adds slowly in dil. Et_2O soln. to form a faintly yellowish *diiodide*, m. 70°, different from the product, m. 2.5–3°, obtained by Howell and Noyes by chlorination of IC : CI. The 2 compds. are very probably *cis-trans* isomers. C. A. R.

The relative loading of the molecules of alcohols, aldehydes, ketones and carbohydrates and their solubility. M. A. RAKUZIN. *Biochem. Z.* 226, 133–8(1930).—Interesting theoretical considerations. S. MORGULIS

The action of ethylmagnesium bromide and oxidants on diethyl polysulfides. A. VARONI. *Atti accad. Lincei* 11, 905–9(1930).—In 2 previous papers (*C. A.* 23, 4927, 5158) the prepn. and probable constitution of di-Et polysulfides are given. In order to help substantiate these formulas, the action of Grignard reagents, as well as oxidizing agents on them, has been studied. Results with the first of these were inconclusive as the mols. were disrupted with formation of monosulfides, mercaptan, and free S. However, with oxidizing agents trisulfoxides were obtained. Dil. HNO_3 produces *di-Et trisulfoxide*, EtSOSOSOEt by adding the acid drop by drop to any of the polysulfides (*tri-*, *tetra-*, *penta-*), and then distg. under 20 mm. pressure at 154–5°. It is a liquid with a very bad odor, sol. in H_2O, EtOH and Et_2O, and is reduced by Zn and acids to a mercaptan, d_4^{20} 1.2844. Using fuming HNO_3, *di-Et disulfone*, $EtSO_2SO_2Et$, is formed from the disulfide, and the *trisulfone* $EtSO_2SO_2SO_2Et$ from the higher derivs. These sep. from the reaction liquid by crystn., and m. 50° and 32°, resp., d_4^{20} 1.3035 and 1.5048, resp. The non-formation of any deriv. higher than the tri-deriv. strengthens the theory that the trisulfide has a constitution —S—S—S—, while the higher derivs. have constitutions —S—S—S and —S—S—S or —S—S—S—.

A. W. CONTIERI

Continuous hydrocarbon nitration process, with special reference to the Buhtz mixer. VON BEZOLD. *Nitrocellulose* 1, 171–3(1930); cf. *C. A.* 24, 5714. E. M. S.

Preparation of nitromethane. ISAMI HIRANO. *J. Pharm. Soc. Japan* 50, 869–71 (1930).—$ClCH_2CO_2Na$, prepd. by treating $ClCH_2CO_2H$ (200 g.) in water (400 cc.) with Na_2CO_3 (120 g.), was treated in the cold with $NaNO_2$ (120 g.) in water (200 cc.) and satd. with NaCl and the reaction mixt. was steam distd. The crude product was dried over $CaCl_2$ and distd. with a small quantity of HgO. A yield of 52.7–53.1% was obtained. F. I. NAKAMURA

Sulfurous acid esters and their uses in syntheses. WALTER VOSS. *Metallbörse* 20, 1854–5(1930).—To prep. sym. $O:S(OR)_2$ (I), alcs. were decompd. by $SOCl_2$. By suitable reaction conditions, yields 3 times better than those given in the literature were obtained. I can be used as alkylating agent, *e. g.*, for Ph esters, and alkylating of aniline. I has advantages over dialkyl sulfates in the case of high alkyls. I and unsym. H_2SO_3 esters (II) differ, II sapong. in acid soln. very slowly, in alk. soln. rapidly, the reverse being true of I. The reaction $SO(OR)_2 + H_2O = SO_2 + 2ROH$ can be used for coupling, *e. g.*, the formation of carboxylic acid esters, and alcs., of acetals of aldehydes and ketones, of glucosides from sugars and alcs. Betaine can be formed from I and amino acids. E. M. SYMMES

The identification of aliphatic amines. A. NYASSNA. *Ing. Chim.* 15, 40–54

(1930).—N. has detd. the consts. of the HCl salt, chloroplatinate, picrate, chloroaurate, picrolonate and styphnate of *mono-, di-* and *trimethylamine, mono-, di-* and *triethylamine, mono-, di-* and *tripropylamine, isopropylamine, amylamine, isoamylamine, hexylamine, heptylamine, octylamine, allylamine, betaine* and uses the m. p. and cryst. form as means of identification. P. THOMASSET

Distillation of Grignard reagents. HENRY GILMAN AND ROBERT E. BROWN. *J. Am. Chem. Soc.* 52, 4480–3(1930).—In connection with studies on the following systems present in solns. of Grignard reagents: $2RMgX \rightleftharpoons R_2Mg + MgX_2$ and $RMgX \rightleftharpoons R^- + {}^-MgX$, it is shown that some RMgX compds., or their equivs., can be distd. in a stream of Et_2O. With MeMgI there was slight evidence of distillate in about 1 week; with EtMgBr and EtMgI there was no evidence of distillate until about the 10th day. With PhMgBr some Ph_2 was isolated. The high-vacuum sublimation of RMgX compds. gives R_2Mg compds. Of the 3 R_2Mg compds. which were sublimed, Me_2Mg was most volatile; Bu_2Mg was less volatile than Et_2Mg. C. J. WEST

Thermal decomposition of gaseous germanium tetraethyl. RAY L. GEDDES AND EDWARD MACK, JR. *J. Am. Chem. Soc.* 52, 4372–80(1930).—The thermal decompn. of gaseous $GeEt_4$ in the temp. range 420–50° is about 98% homogeneous and unimol. down to a pressure of about 8 cm. At about 7 cm. the value of the velocity const. begins to fall off, but the addn. of H gas to the reaction system does not raise the const. appreciably. The energy of activation is about 51,000, with a possible error of several thousand calories, and the velocity const. is given by the equation, $\ln k = 32.88 - 51{,}000/RT$. The no. of active degrees of freedom calcd. at the pressure where the velocity const. begins to fall off is between 8 and 10. The reaction yields metallic Ge; analysis of the gases from the decompn. shows essentially the products obtained by pyrolysis of C_4H_{10}. Added H and C_2H_4 enter into hydrogenation and polymerization reactions in the gaseous system. Added CO_2 cuts down the velocity const., but N, He and A have little, if any, effect. It seems justifiable to measure the course of this decompn. by pressure changes; the pressures were measured with quartz and pyrex membrane manometers. C. J. WEST

Boron. II. Action of lithium on ethylamminoboron trifluoride. CHARLES A. KRAUS AND EARL H. BROWN. *J. Am. Chem. Soc.* 52, 4414–8(1930); cf. *C. A.* 23, 5124.—Ethylamminoboron trifluoride is aminolyzed in $EtNH_2$; this soln., treated with 3 atoms metallic Li, gives LiF, H_2 and boron triethylimine, $B(NHEt)_3$; this is a liquid readily sol. in $EtNH_2$, appreciably volatile at room temp. and readily hydrolyzable by H_2O vapor. An app. is described for the reaction with Li. C. J. WEST

Methyltin derivatives. VI. Reaction between chloroform and sodium trimethyl stannide in liquid ammonia. CHARLES A. KRAUS AND ARTHUR M. NEAL. *J. Am. Chem. Soc.* 52, 4426–33(1930); cf. *C. A.* 24, 1617.—$CHCl_3$ and Me_3SnNa in liquid NH_3 give Me_3Sn and *di-trimethyl stannyl ethylene* (I), b. 194–5°; I is inactive toward Br at room temp., but in boiling CCl_4 bromination takes place slowly; NH_3 ppts. *diammino-dimethyltin dibromide*, the reaction being $I + 4Br_2 = 2Me_2SnBr_2 + 2MeBr + 2C_2H_2Br_2$. Reduction of I with Na in liquid NH_3 gives an equimol. mixt. of Me_3SnNa and $CH_2{:}CHSnMe_2Na$, along with CH_4 and $NaNH_2$. On adding MeI to this mixt. there is produced a mixt. of Me_4Sn and *trimethylvinyltin*, which has not yet been obtained pure. CCl_4 reacts readily with Me_3SnNa, the chief product being Me_3Sn; Et_3SnNa reacts similarly. C. J. WEST

Olefinic acids. III. Homologs of teraconic, terebic and pyroterebic acids. Further evidence of the effect of two γ-alkyl groups on three-carbon tautomerism. REGINALD P. LINSTEAD AND JASON T. WM. MANN. *J. Chem. Soc.* 1930, 2064–73; cf. *C. A.* 24, 5286.—The striking stability toward alk. reagents of pyroterebic acid, its Et ester and the related Me ketone has provided the only evidence of the large effect of 2 γ-alkyl groups in favoring the β,γ-phase of a 3-C system. Confirmatory evidence of this general principle is now reported from a study of $MeCH_2CMe{:}CHCH_2CO_2H$ (I). Condensation of 72 g. MeEtCO and 174 g. $(CH_2CO_2Et)_2$ with dry EtONa in Et_2O gives a mixt. of 45 g. $MeCH{:}CMeCH(CO_2H)CH_2CO_2H$ (II), m. 141°, and 10 g. $MeCH_2CMe{:}C(CO_2H)CH_2CO_2H$ (III), m. 186° (Stobbe, *Ann.* 282, 280(1894)). II, by Stobbe's method, yields β-bromo-β,γ-dimethylbutyrolactone-α-acetic acid, m. 160–1°, which yields mixed products on reduction with Zn and AcOH or with Na-Hg. Heating II or III with 48% HBr or 50% H_2SO_4 gives a mixt. of γ-methyl-γ-ethylisoparaconic acid (IV), m. 128°, probably identical with Stobbe's acid, m. 125–6°, and *γ-methyl-γ-ethylparaconic acid* (V), m. 146°. V was also obtained by hydrolysis of Et γ-hydroxy-β-carbethoxy-γ-methylhexoate, b_{15} 150–70° (not further purified), obtained in 33 g. yield from EtMgI and Et acetosuccinate; prepn. of V from *sec*-butylsuccinic acid by oxidation was abandoned as no appreciable quantity of the

intermediate ester, $MeCH_2CHMeC(CO_2Et)_2CH_2CO_2Et$, could be prepd. $MeCH_2CHMeCHO$ (VI), b. 92–3°, was prepd. from MeEtCHMgBr and $H(CO_2Et)_3$ in about 25% yields; *semicarbazone*, m. 103°. γ-Methyl-γ-ethylglycidic ester, obtained in 56% yield from MeEtCO and $ClCH_2CO_2Et$ with dry EtONa, b_{17} 91–5°, gives quant. a Na salt, the free acid from which, on slow distn. *in vacuo*, gives some 15% of crude VI. V (23 g.), heated as rapidly as possible, distils without charring at 260°, giving 6.7 g. of *γ-methyl-Δβ-hexenoic acid* (I), b_{12} 118°, $d_4^{16.7}$ 0.9644, $n_D^{16.7}$ 1.4512 (on standing 6 weeks there results 25% of high-boiling material), and 3.9 g. of γ-methyl-γ-ethylbutyrolactone, b_{10} 103–4°, $d_4^{16.5}$ 0.9983, $n_D^{16.5}$ 1.4460. VI, $CH_2(CO_2H)_2$ and C_5H_5N, kept 4 days at room temp. and then heated some hrs. on the H_2O bath, give 80% of *γ-methyl-Δα-hexenoic acid* (VII), b_{18} 125°, does not solidify at −15°, $d_4^{20.3}$ 0.9441, $n_D^{20.3}$ 1.4526; acid chloride, b_{11} 65–6°; *anilide*, m. 110°; *p-toluidide*, m. 92°. The equil. mixt. of I and VII contains 77% of I and the mobility $10(k_1 + k_2)$ was 3.1 (t in hrs.). The equilibrated VII, treated by the process of partial esterification, readily yielded I. I gives an acid chloride, b_{16} 64–8° (contains traces of Cl compds.); *anilide*, m. 91°.

C. J. West

Rearrangement and transformation of oleic acid. K. H. Bauer. *Metallbörse* 20, 1912–3(1930).—Oleic acid (I) at 180° with $ZnCl_2$ gives γ-stearolactone, a hydroxystearic acid, m. 83°, and an isoöleic acid. If I is heated with $ZnCl_2$ in AcOH for 16–20 hrs., there results an isoöleic acid, m. 42°, and a hydroxystearic acid, m. 77–9°. Oxidation indicates that a Δ^{10}-isoöleic acid is formed. The two isomeric dihydroxystearic acids obtained by oxidation of I with $KMnO_4$, on heating at 180–200°, split off H_2O, giving the so-called estolide; on further heating at 300° there results 10-ketostearic acid in 60–70% yields.

C. J. West

Unsaturation phenomena of acetylenic acids and esters. III. Constitution of some mercury derivatives. Wm. Whalley Myddleton, Arthur W. Barrett and John H. Seager. *J. Am. Chem. Soc.* 52, 4405–11(1930); cf. *C. A.* 21, 3348.—Me octinecarboxylate and $Hg(OAc)_2$ give a *Hg compd.*, $Me(CH_2)_5C(OHgOAc):C(HgOAc)\text{-}CO_2Me$; decompn. with concd. HCl gives about 25% of Me β-ketononoate, b_{23} 137.5°, which shows 13.5% of the enolic form 1 hr. after isolation. The Hg deriv. is very slightly sol. in hot EtOH and neutral aq. $FeCl_3$ gives in about 1 min. a faint reddish violet color. PhC : CCO_2Et gives a *Hg compd.*, $C_{13}H_{16}O_7Hg_2$; decompn. with HCl gives about 27% of ketonic compd., which contains 20% of the enolic form after 1 hr. The cold EtOH soln. gives in a few secs. a deep reddish violet color with 2 drops aq. $FeCl_3$. 1-Heptine gives the *Hg compd.*, $C_{13}H_{20}O_7Hg_3$; HCl gives about 13% of MeCOAm. 1-Octine gives the *Hg compd.*, $C_{14}H_{22}O_7Hg_3$; concd. HCl gives 14% of $MeCOC_6H_{13}$. PhC : CH and PhC : CCO_2H give *Hg compds*, $C_{14}H_{14}O_7Hg_3$ and $C_{13}H_{11}O_7Hg_{2.5}$, which give BzMe with HCl. The Hg deriv. of stearolic acid with Cl and Br in $CHCl_3$ gives the *chloro-* and *bromoketostearic acids*, viscous oils (Na, Li and K salts, soapy; Ca, Ba and Pb salts, cheese-like solids; Me and Et esters do not distil at 2 mm.; reduction gives 10-ketostearic acid). The Hg deriv. of behenolic acid gives the *13-chloro-* and *13-bromoketobehenic acids*, viscous oils. The Hg salt of Me octinecarboxylate and Br give *Me dibromoketononoate*, b_{14} 169°. PhC : CCO_2Et, as the Hg deriv., and Br give *Et benzoyldibromoacetate*, b_{15} 194°. The Hg deriv. of 1-heptine and Br give *tribromomethyl Am ketone*, $b_{2.5}$ 120°. The Hg deriv. of 1-octine and Br give the corresponding *hexyl ketone*, $b_{6.5}$ 137°. PhC : CH as the Hg deriv. reacts very slowly at low temps. PhC : CCO_2H as the Hg deriv. and Br give the *ω-tribromoacetophenone*, b_{14} 174°. 10,11-Undecinoic acid (Hg deriv.) and Cl give quant. trichloroketoundecoic acid, viscous oil (Me and Et esters could not be distd. at 2 mm.); 20% NaOH gives $CHCl_3$ and Me sebacate.

C. J. West

The polymerization of methyl esters of highly unsaturated fatty acids. III. The polymerization products. K. Kino. *J. Soc. Chem. Ind., Japan* 33, Suppl. binding 305–10(1930); cf. *C. A.* 24, 3487.—Heating of the Me esters of acids with 4 or 5 double bonds in a H_2 atm. at temps. ranging from 230° to 290° is thought to result in the selective formation of polymers with a tetra-C ring which are probably not dimers. In the case of acids with 3 double bonds a dimeric homolog with a tetra-C ring is probably formed. The formation of the tetra-C ring is probably facilitated by the presence of many double bonds. IV. **Attempt to isolate the ester with a tetra-C ring formed by the intra-combination of double bonds in a molecule.** *Ibid* 311–2.—No conclusive results were obtained.

L. F. Audrieth

Replacement of positive hydrogen by halogen. I. Fritz Straus, Leo Kollek and Walther Heyn (in part with Ruth Köhnel). *Ber.* 63B, 1868–85(1930).—When CH : CH, HC : CC : CH and their derivs. contg. H on the triply bound C atom are

treated with aqueous hypochlorites or hypobromites the H atoms are replaced with surprising rapidity and smoothness by halogen. The reaction takes place only in alk. soln.; the hypohalites were generally used in 0.5–0.7 *N* solns. in the presence of 4 mols. free alkali, but the amount of the latter can be increased to 8 mols. without markedly influencing the velocity of the reaction. In such strongly alk. soln. any hydrolysis of the salts is excluded and the transformation can be only a reaction of the hypohalite ion: $RC:CH + XO' \longrightarrow RC:CX + HO'$. The velocity of the reaction of the hypohalites varies with the nature of the halogen inversely as their stability; the hypochlorite requires for half-transformation about 10 times as long as the hypobromite, while the hypoiodite, judging from the work of Biltz and Küpper, reacts practically instantaneously. That the reaction is dependent upon the positive nature of the replaced H atom and not on some peculiarity in the finer structure of the C:C union is shown by the fact that the reaction takes place equally readily with the positive H in cyclopentadiene (I) and the closely related indene (II), but because of the migratory property of the unsatd. bonds which is characteristic of these compds., the reaction does not stop at the first stage; in I all 6 of the H atoms are at once replaced by halogen, and in II 3 H atoms are replaced. The reaction can be conceived as passing through the following intermediate stages, a common characteristic of which is a tendency of the unsatd. bond to shift as much as possible to C atoms already carrying halogen:

In spite of their complexity, the reactions proceed with extraordinary rapidity, especially with I; when the soln. of I in petroleum ether is shaken with the KOBr soln., the heavy crystals of the hexabromide (III) begin to sep. in about 10 min. and the yield surpasses 50%. With indene, which, however, requires about 50 hrs. for complete reaction, the yield reaches 70%. Fluorene, in which the unsatd. bonds of the cyclopentadiene ring are anchored in the aromatic systems, does not undergo the reaction. The relative velocities with which the different compds. react can be compared only to a very limited extent. Only a part of them are H_2O-sol. and expts. in heterogeneous systems involve many sources of error because of irregularities in shaking, in the degree of emulsification, etc., and therefore no curves are given. Some of the differences observed are so great, however, that they must have a meaning; *e. g.*, heptine reacts at least 10 times more slowly than PhC:CH, the velocity of whose reaction is of the same order of magnitude as that of the *tert* acetylenecarbinols of the type $R_2C(OH)C:CH$. The new method affords a materially simpler and in some cases the only means of prepg. the halogen-substituted simple acetylenes, and has made it possible to fill in 2 gaps: ClC:CCO_2H (IV) and ClC:CCl (V) (after this work had been completed, it was found that Böeseken and Carrière (*C. A.* **8**, 3296) had already prepd. V by heating $(CCl_2:CClCO_2)_2Ba$, and Ott and Ottemeyer (Ottemeyer, *Diss. München*, **1926**) have also obtained it by distn. of $CCl_2:CHCl$ over KOH, but they state that the method is dangerous and unreliable). V is formed smoothly from C_2H_2 and hypochlorite ions but a greater excess of free alkali is required than in any other case studied. It is a liquid b. 32° which explodes with unbelievable violence on the slightest contact with O, although it shows no other evidence of special instability and is stable to light. The dangerous explosions which have sometimes occurred in the purification of C_2H_2 with hypochlorite were likely due to the formation of V. The hypochlorite solns. were generally prepd. by passing Cl into 12.5% KOH in ice until litmus was just bleached and then dilg. with an equal vol. of 2 *N* KOH, the KOBr solns. from 25 cc. Br, 180 g. KOH and 800 cc. H_2O at 0°. When C_2H_2 is passed into the KOCl soln. undild. with KOH violent explosions occur; these cease if an equal vol. of 12.5% KOH is first added to the KOCl, but there is no apparent further reaction (manifested by the odor, slight turbidity and peculiar crackling) unless the added KOH corresponds to an equal vol. of 25% soln. V, prepd. by passing a mixt. of C_2H_2 and N_2 into the KOCl-KOH soln. in ice, seps. as an oil solidifying in CO_2-Me_2CO in needles, m. —66° to —64.2°, b_{748} 32–3°. It explodes violently in contact with air; if the C_2H_2 is passed a short time into the KOCl until a slight turbidity is formed and the soln. is shaken with air, there are observed a characteristic crackling and (in the dark) distinct sparks due to little explosions; when enough of the V vapor has collected over the soln. and the test tube is shaken, a long flame shoots out with a whistling sound; N_2 laden with the V vapor forms in the air thick white fumes with a $COCl_2$-like odor. In (halogen-free) Ilosvay soln. there is formed a yellow turbidity, rapidly increasing and changing

to orange and, in about 10 min., yielding the red-brown Cu acetylene; $AgNO_3$ in H_2O or alc. gives white curdy ppts. more or less sensitive to light and not formed in the presence of NH_4OH. V is not sensitive to light (Mg ribbon at a distance of 15 cm.). In excess of CCl_4 it forms C_2Cl_6 after 9 hrs. and with Br water it gives $(CClBr_2)_2$, m. 209–10° (sealed capillary). BrC:CBr, m. —25° to —23°, gives $(CBr_2:)_2$, m. 55–7°, with Br in $CHCl_3$ under H_2O, and $(CBrI:)_2$, m. 93° (crude), with I. *Chloropropiolic acid* (IV) (5.8 g. from 20 g. CH:CCO_2H), m. 69–70°, reddens tropeolin and blues Congo in even very dil. soln., gives no yellow ppt. with Ilosvay soln. even when dil. AcOH is added, gives red Cu acetylene when boiled, produces deep, purulent, slow-healing lesions on the skin and is quite toxic (80 mg./kg., subcutaneously, of the Na salt killed rabbits in 3 hrs.). When once isolated, IV is stable for months, but it rapidly decomps. into ClC:CH, CO_2 and $CH_2(CO_2H)_2$ when boiled in aq. $Ba(OH)_2$ under H. The conversion into $CH_2(CO_2H)_2$ is also effected by cold alkalies. With concd. HCl on the H_2O bath it gives *β,β-dichloroacrylic acid*, m. 76–7°. BrC:CCO_2H (yield, 74%) m. 84–6° after careful drying *in vacuo* over H_2SO_4; fresh prepns. melt lower, apparently because of the existence of a hydrate; with Br it gives $Br_2C:CBrCO_2H$, m. 116–8°. PhC:CBr (yield, 87.7%) b_{13} 88–9°; in its prepn. K stearate is added to facilitate emulsification. 1-Bromo-1-heptine (50% yield), b_{13} 57–7.5°, b_{758} 164–5°; 0.2 cc. administered by mouth to a 3.5-kg. dog produced a condition of semi-sleep for 0.5 hr. *Dialkylbromoethinylcarbinols*, RR'C(OH)C:CBr: *Di-Me*, b_{15} 68°, d_4^{20} 1.4577, d_4^{25} 1.4505; *methylethyl*, $b_{14.5}$ 76.5°, d_4^{20} 1.3849, d_4^{25} 1.3783; *di-Et*, $b_{14.5}$ 87°, m. 16–7.5° (*p-nitrobenzoate*, yellowish, m. 75.5–6°; *p-nitrobenzoate* of the Br-free carbinol, m. 54–7.5°); *methyl-tert-butyl*, $b_{14.5}$ 89°, m. 38–9°, does not autoxidize even in O, has a surprising tendency to rapidly absorb H_2O to form a *hemihydrate*, m. 52–2.5°. *1-Bromoethinylcyclohexanol* (yield, 94–5%), m. 55.5–6.5°, b_{12} 113.5–4°, $b_{0.2-0.4}$ 89–90°; *p-nitrobenzoate*, faintly yellowish, m. 90.5–1°, reduced by $TiCl_3$ to the *p-aminobenzoate*, m. 127–7.5° (*p-nitrobenzoate* of the Br-free carbinol, m. 66–6.5° (cor.); *p-aminobenzoate*, m. 97–8.5° (cor.)). *1-Chloroethinylcyclohexanol* (yield, 90%), m. 51.5–2°, b_{13} 98°. **III**, deep yellow, m. 86–7°, $b_{0.25}$ 147° without decompn. when distd. in small amounts, mol. wt. in C_6H_6 522.4. *Hexachloride* (yield, 44%), b_1 78–9°, mol. wt. in C_6H_6 251. *1,1,3-Tribromoindene*, m. 104.5–5°. *1,1,3-Trichloroindene*, m. 76°, b_{18} 134°. **II. Dihalogenodiacetylenes.** Fritz Straus, Leo Kollek and Heinrich Hauptmann. *Ibid* 1886–99.—Aq. hypohalite solns. are almost immediately rendered turbid by diacetylene, and the *dichloro-* (I) and *dibromodiacetylene* (II), like the di-I compd. (III), sep. in long needles; they m. 2–3°, 49–50° and 101.2°, resp., and explode 73°, 67° and 102°. The explosion temp. of I is that of a solid, black-brown transformation product into which the melt changes with increasing color as the temp. is raised, while II and III likewise darken on fusion but explode while still in liquid form. On account of their instability I and II were not analyzed but were identified by their halogen addn. products $(CI:CCII)_2$ (IV), $(CBr:CBr_2)_2$ (V) and $(CI:CBrI)_2$ (VI). The halogen adds symmetrically to both double bonds; otherwise only 1 form of each could be produced, while as a matter of fact a homogeneous product is obtained only when the entering halogen is the same as that already present (V and the $(CI:CI_2)_2$ previously described). IV, VI and $(CBr:CIBr)_2$ (VII) are not homogeneous (theoretically 3 *cis-trans*-isomers are possible); because of their very similar solubilities the isomers were not always isolated (2 forms of VI, 1 of IV). The dihalogenodiacetylenes are subject to both autoxidation and polymerization; the velocity of both processes increases with increasing electroaffinity of the halogen. III takes up O hardly perceptibly; after many days the increase in wt. was only 0.3–0.5% (corresponding to about 0.1 atom O), and the change which the mol. undergoes is almost exclusively polymerization. I and II, on the other hand, react very energetically with the dild. O of the air and polymerization occurs only when O is excluded. When a thin layer of an Et_2O soln. of II is allowed to evap. the needles which sep. disappear in a few min. with formation of a characteristic mist, and leave no residue; if the heat of reaction is sufficient to melt the material which has not yet reacted, it quickly explodes. Among the gaseous reaction products are hydrolyzable Br and O_3. The limited availability of diacetylene was a great obstacle in carrying out these expts. which, however, gave the impression that the halides of diacetylene are less dangerous to handle than those of C_2H_2. However, both series behave so similarly that they must have similar structures. The unlikelihood of a structure $Cl_2C:C:C:C<$ for such stable compds. and the fact that, according to the principles of acetylide chemistry, such a structure on halogenation would first be satd. at the end to form a compd. $Cl_2C:C:C:CX_2$, which on addn. of 2 more halogen atoms could not yield stereoisomeric forms without a migra-

tion of the end halogen atoms, lead the authors to retain the sym. structure for the dihalogenoacetylenes and -diacetylenes; the newer conceptions of polar atoms and the doctrine of activated states of the mols. seem to offer enough possibilities to explain the properties of these compds. The polymerization phenomenon is especially characteristic in the cryst. forms. If the pure white needles of III are allowed to stand, they change in 10–14 days, without alteration in cryst. form, through yellow to brown-black, with metallic luster, become practically insol. in Et_2O, and are not visibly attacked by Br in $CHCl_3$ or I in Et_2O. Their I content decreases slightly (from 84.09 to 82–3%) and they increase in wt. 0.3–0.5%, as already stated. In this condition the crystals are highly explosive and sensitive to friction and shock. If they are allowed to stand still longer, however, the sensitivity decreases and after 3–4 months they can be quietly powd. and at most deflagrate weakly when touched with a hot wire. II undergoes the same change, but more rapidly (within 24 hrs.), and I even more rapidly (with I, it was not noticed whether it passes through an intermediate stage of high sensitivity). All these compds. are stabilized by the process of soln.; I, II and III can be recovered unchanged after 8 days in Et_2O, petroleum ether or C_6H_6, and $(C:CCO_2H)_2$ (VIII) is stable for weeks in Et_2O in the dark. Both C_2I_2 and III, however, undergo a peculiar disproportionation when heated in soln. III gives $(CI:CI_2)_2$ but in far less amount than is demanded by the equation $3C_4I_2 = C_4I_6 + 8C$, and the accompanying black insol. product contains 70% and more of I and in some cases is still explosive; the disproportionation is evidently accompanied by polymerization. The C_4I_6 can be obtained almost quantitatively after boiling 2.5 hrs. in Et_2O, petroleum ether and alc., and to the extent of about 50% from MeCN or C_6H_6; after boiling 18 hrs. in C_6H_6 only 16% can be recovered. $(C:CH)_2$ reacts like C_2H_2 with alkylmagnesium halides, but much more easily and smoothly, since it dissolves in Et_2O, to form the bis(magnesium halide) which can be used for the prepn. of derivs. of the $(C:CH)_2$. In this way were obtained VIII (yield, 5%) and glycols of the type $[C:CC(OH)RR']_2$ (IX), which occur in 2 stereoisomeric forms when R and R′ are different; the compd. with R = R′ = H could not be obtained (from HCHO); that with R = R′ = Me, unlike the C_2H_2 analog, has no pharmacol. action. These glycols are quite stable and can even be distd. in a high vacuum. The ester of VIII could not be prepd. Attempts to prep. diphenyltetraacetylene from C_2I_2 with PhMgBr resulted in an almost quant. interchange of the I and MgBr: $C_2I_2 + 2PhMgBr \longrightarrow 2PhI + C_2(MgBr)_2$. *1,4-Dichloro-1,2,3,4-tetraiodobutadiene* (IV), lemon-yellow, m. 155–7°. *1,1,2,3,4,4-Hexabromobutadiene* (V), m. 52–4°. *1,4-Dibromo-1,2,3,4-tetraiodobutadiene* (VI), lemon-yellow prisms, m. 160–2°, and needles, m. 128–30°. III (yield of crude product, 92%), gives with Br in $CHCl_3$ *1,4-diiodo-1,2,3,4-tetrabromobutadiene* (VII), yellowish leaves and needles which could not be sepd., m. 57–60°. *3,5-Octadiine-2,7-diol* (IX, R = H, R′ = Me), from $(C:CMgBr)_2$ and AcH, m. 108–9°, $b_{9.3}$ 94–136° (partial decompn.), changes after several days into a violet polymer, insol. in the usual solvents, even when heated; Lespieau's isomer, m. 68°, could not be isolated from the residual oil. *2,7-Dimethyl-3,5-octadiine-2,7-diol*, obtained in 69% yield with Me_2CO instead of AcH, m. 129–30°. *2,7-Di-Ph analog*, obtained in 40% yield although in the prepn. of the Grignard compd. the reagents were used in the proportions calcd. for HC:CMgBr, prisms, m. 195°, mol. wt. in camphor 291.6; the mother liquors yielded needles, m. 142–3°. Earlier attempts to regenerate $(C:CH)_2$ from the $CHBr_2CBr_2CBr:CHBr$ by removal of the Br had resulted in the formation of $(CH:CH_2)_2$ and a small amount of a substance which, by analysis of its Cu and Ag compds., has now been identified as $CH_2:CHC:CH$. This is due to the fact that, unlike $(CH:CH_2)_2$, $(C:CH)_2$, in spite of its lower b. p., is to a large extent held back by the refluxing solvents (Et_2O, Me_2CO) and thereby subjected to a further (hydrogenation) reaction; if the hexabromides are heated only a short time in alc. with Zn, the soln. contains $(C:CH)_2$, which can be isolated almost quantitatively as the Cu compd. This removes the last doubt as to the bromides being related to $(C:CH)_2$ and having the open structure. C. A. R.

Decomposition of ethylene glycol in the presence of catalysts. I. Vanadium pentoxide as catalyst. Nathan L. Drake and Thomas B. Smith. *J. Am. Chem. Soc.* 52, 4558–66(1930).—The reaction C_2H_4 (g.) + $0.5O_2$ (g.) + H_2O (l.) = $(CH_2OH)_2$ is thermodynamically sound, since $\Delta F_{298} = -40{,}957$ cal. If a catalyst could be found which would render possible the production of the oxide, the synthesis of $(CH_2OH)_2$ from C_2H_4, air and H_2O should be possible. This is the beginning of a study of the effect of catalysts on the decompn. of $(CH_2OH)_2$. In the presence of V_2O_5 the principal products of decompn. are AcH and C_2H_4; the use of a fresh catalyst favors C_2H_4 formation while AcH is formed in about equal amts. by fresh or used catalysts. The

mols. formed by a fresh and a used catalyst at 360° are: CO_2 0.0045, 0.0023; C_2H_4 0.0196, 0.0145; CO, 0.0071, 0.0044; AcH, 0.0040, 0.0436; AcOH, 0.0033, 0.0019. An app. is described for the reaction; the results of various runs under different conditions of temp. are given in curves. C. J. WEST

Ether and ester. III. Diethylene dioxide. J. VAN ALPHEN. *Rec. trav. chim.* **49**, 1040–4(1930).—In a previous communication v. A. has shown that the formation of water and ether from EtOH is an equil. reaction, which is catalyzed by H (or H_3O) ions and by salts of weak bases and strong acids, especially anhyd. $Fe_2(SO_4)_3$ being an excellent catalyst (*C. A.* **24**, 4757). On distg. glycol with 4% H_2SO_4 Favorski obtained diethylene dioxide [*J. Russ. Phys.-Chem. Soc.* **38**, 741–55(1906)], the formation of which was explained in the same way as the formation of ether from alc. by Williamson. This assumption is, however, improbable for Fe III chloride and sulfate and Al sulfate also transform the glycol into diethylene dioxide. The dioxane obtained from glycol with anhyd. $FeCl_3$ was contaminated with a chlorinated product which could not be removed by distn., while the yield was only small on heating glycol in a sealed tube at 155–60° with $Fe_2(SO_4)_3$, much tarry material being formed. Much better yields were obtained by a continuous method: anhyd. $Fe_2(SO_4)_3$ (6 g.) was mixed with glycol (20 cc.) and to the boiling mixt. glycol was added (150 cc.) drop by drop as quickly as the liquid distd. The $Fe_2(SO_4)_3$ is reduced in this process to $FeSO_4$ which, however, shows the same catalytic activity. Dioxane is not split by HNO_3 at low temp.; on adding abs. HNO_3 to frozen dioxane at —10° or to the well-cooled soln. in CCl_4 a cryst. addn. product, m. 14°, is obtained, consisting of 3 mols. of dioxane with 4 mols. HNO_3 and thus being probably 2 mols. of dioxane dinitrate, crystg. with 1 mol. dioxane of crystn. When Br acts upon dioxane at a higher temp. in the presence of $FeBr_3$, only water, HBr and $(CH_2Br)_2$ were obtained along with a large quantity of tarry products. C. F. VAN DUIN

Decomposition of mercaptans in alkali solutions. E. C. BILLHEIMER AND E. EMMET REID. *J. Am. Chem. Soc.* **52**, 4338–44(1930).—An app. has been developed and a quant. method of analysis established for the investigation of the decompn. of mercaptans in alk. soln. The mercaptans decomp. in a definite and reproducible manner, 3 simultaneous reactions taking place: $RSH + 2NaOH = ROH + Na_2S + H_2O$; $2RSH + 2NaOH = R_2S + Na_2S + 2H_2O$; $EtSH + 2NaOH = C_2H_4 + Na_2S + 2H_2O$. In the case of BuSH, about half of the product is decompd. in 2 hrs. at 260° with 3 *N* NaOH; using these conditions the following figures were obtained for the % of total decompd. and R_2S formed: Et 55.4, 20; Pr 52.2, 23; Bu 49.6, 16; iso-Bu 36.2, 16; Am 42.9, 23; C_6H_{13} 37, 8; C_7H_{15} 35, 30; iso-Pr 65.4, 8; *sec*-Bu 59.1, 4; *sec*-Am 56, 11; *sec*-C_6H_{13} 48.8, 7; *sec*-C_7H_{15} 47, 33. The octyl and nonyl mercaptans yielded insol. Na derivs. The total decompn. decreases as the no. of C atoms increases; the sec. mercaptans react more rapidly than the corresponding primary derivs. With very dil. alkali the % of alkyl sulfide is high when it is compared with the total decompn. At 250° in 4 hrs. BuSH gives slightly less decompn. than at 260° in 2 hrs., showing that the reaction has about the usual temp. coeff. The proportion of Bu_2S formed is somewhat higher at the lower temp. In pure H_2O the % of mercaptan reacted was found to be practically 0. C. J. WEST

The chlorination of formylmethionic acid. H. J. BACKER. *Rec. trav. chim.* **49**, 1054–6(1930).—The chlorination of $HCOCH(SO_3H)_2$ easily leads to the formation of *formylchloromethionic acid;* on passing Cl into 1.3 *N* aq. $HCOCH(SO_3K)_2$ (cf. *C. A.* **23**, 3209) on the water bath, the K formylchloromethionate, $C_2H_3O_8ClS_2K_2$, may be obtained by the addn. of EtOH to the concd. soln. in 67% yield. In this compd. the 1 mol. water of crystn. probably is chemically bound to the aldehyde group as in chloral hydrate. This salt consumes exactly 1 mol. of alkali at room temp. in the course of 0.5 hr. with the formation of $CHCl(SO_3H)_2$ and may be estimated quantitatively in this way. The presence of the aldehyde group can be shown by the formation of an *oxime*, $C_2H_3O_7NS_2ClK_2$, and of a *semicarbazone*, $C_3H_4O_7N_3S_2ClK_2$. The reaction with alkali, mentioned above, affords an easy method for the prepn. of $CHCl(SO_3H)_2$, which so far was obtained only as a secondary product in the sulfonation of $ClCH_2CO_2H$ (*C. A.* **24**, 4760); the $CHCl(SO_3H)_2$ was isolated as the strychnine salt, which, on decompn. with KOH, is converted into the di-K salt, which crystallizes without water of crystn. in monoclinic plates or with $2H_2O$ in triclinic plates. C. F. VAN DUIN

Bromomethanetrisulfonic acid. H. J. BACKER AND K. H. KLAASSENS. *Rec. trav. chim.* **49**, 1045–7(1930).—A comparison of simple polycarboxylic and polysulfonic acids shows that the latter are more stable, *e. g.*, malonic acid loses readily CO_2 on heating its aqueous solution to 68°, while methionic acid is stable, even at much higher temperatures. While methanetricarboxylic acid is only known as the Et ester, meth-

anetrisulfonic acid is a quite stable substance. The authors have made an attempt to prepare methanetetrasulfonic acid by the action of K sulfite on bromomethanetrisulfonic acid; the desired reaction, however, does not take place but a reduction occurs with the formation of methanetrisulfonic acid. *Bromomethanetrisulfonic acid* was prepared by heating methanetrisulfonic acid in 2 *N* aqueous solution with 10% excess of bromine in a sealed tube at 150° during 8 hours; it was isolated as the Pb salt, which was converted into the free acid by means of H_2S and then into the Ba salt; yield 40%. The *free acid* crystallizes with $3H_2O$, $CH_3O_9S_3Br.3H_2O$, m. 179°; *Ba salt* $(CO_9S_3Br)_2$-$Ba_3.8H_2O$; at 25° 100 g. of water dissolve 4.19 g. of this salt; *La salt*, $CO_9S_3BrLa.7H_2O$; *Tl salt*, $CO_9S_3BrTl_3$; *K salt*, $CO_9S_2BrK_3.H_2O$; 100 g. of water dissolve at 25° 1.816 g. of the anhydrous salt. Crystallographic properties of the K salt (P. Terpstra): tet- [illegible] form (111); (111):(11$\bar{1}$) = 63° 13′; (111):(1$\bar{1}$1) =

24 hours gives a solution containing SO_4 ions, while on cooling the [illegible] trisulfonic acid, $CHO_9S_3K_3.H_2O$, is obtained, thus showing that a reduction has taken place.

C. F. VAN DUIN

Mercaptomethanetrisulfonic acid. H. J. BACKER. *Rec. trav. chim.* **49**, 1048–53 (1930).—$C(SO_3H)_4$ cannot be prepared by the interaction of $BrC(SO_3H)_3$ with sulfites (Backer and Klaassens, preceding abstr.); the present paper deals with the attempted prepn. from $HSC(SO_3H)_3$. On passing Cl into CS_2 at 10°, using some I as a catalyst, Cl_3CSCl is obtained (cf. Rathke, *Ber* **3**, 858(1870); Albrecht, *Ann.* **161**, 129(1872)); during the 1st part of the reaction $CSCl_2$ is most probably formed, which in the 2nd part, is converted into Cl_3CSCl with considerable increase of the vol. The crude product contains some S_2Cl_2 but can be easily purified by 2 distns. with steam; it b. 147.5–8° (yield 54%), d_4^{15} 1.698. This compd. with 5 mols. of K_2SO_3 at 60–70° yields the *K mercaptomethanetrisulfonate*, $CHO_9S_4K_3.2H_2O$ (cf. Albrecht, *loc. cit.*) (yield 80%), soly. in water at 25°, 3.21%; crystallographic properties of (P. Terpstra): triclinic pinacoidal class Ci; $\alpha = 100° 8'$; $\beta = 82° 7'$; $\gamma = 94° 54'$; a:b:c = 1.167:1:0.9512; forms: (001); (010); (100); (1$\bar{2}$1); ($\bar{2}$11); (111); (2$\bar{1}$2); ($\bar{2}\bar{2}$1); angles: (100):(010) = 84° 27′; (100):(111) = 62° 17′; (010):($\bar{2}$11) = 64° 29′; (010):(111) = 44° 52′; (001):($\bar{2}$11) = 53° 20′; (111):($\bar{2}$11) = 75° 33′; (010):(001) = 82° 16′; (100):(001) = 96° 59′; (111):(2$\bar{1}$2) = 58° 22′; (212):(1$\bar{2}$1) = 42° 35′; (001):(2$\bar{1}$2) = 46° 51′; (100):(1$\bar{2}$1) = 76° 17′; the sharp bissectrices are nearly perpendicular to (001); $2e$ = 69°; the crystals are not piezoelectric. The oxidation of $HSC(SO_3H)_3$ was attempted with Br at 15° and 50°, with hypobromite, with Cl at 15° or 95°, with hypochlorite and with K_2CO_3 and Cl, but in every case $CH(SO_3H)_3$ was obtained. For details the original paper is to be consulted.

C. F. VAN DUIN

Synthesis of β-glycerides. MAX BERGMANN AND NEAL M. CARTER. *Z. physiol. Chem.* **191**, 211–21(1930).—β-Monoglycerides of fatty acids have not hitherto been prepd. A method is now described in which the cyclic α,α′-benzalglycerol is acylated on the β-OH and then the benzal group removed by catalytic hydrogenation. The yield of β-glyceride is 80% or better. The mixt. of isomeric benzalglycerols obtained by condensation of glycerol with BzH was treated with dry HCl in the cold to rearrange the α,β′- into the α,α′-form and a 90% yield of the latter was thus obtained. The product can be purified by sublimation. Its β-Bz deriv. was hydrogenated in EtOH with Pd catalyst and evapd. *in vacuo* to crystn., yielding 98% of *β-benzoylglycerol*, m. 72.5°. The latter can be condensed again with BzH to form the original substance. A similar condensation can be made with MeAc in the presence of $CuSO_4$, yielding 80% of *β-benzoyl-α,α′-isopropylideneglycerol*, m. 33°. When this is mixed with the isomeric α-benzoyl-α′,β-isopropylideneglycerol, m. 34.5°, liquefaction occurs. Acetylation of α,α′-benzylideneglycerol (I) with Ac_2O and pyridine gave 94% of *β-acetyl-α,α′-benzylideneglycerol*, m. 101°. Hydrogenation converted this into *β-acetylglycerol*, a viscous oil, $b_{0.2}$ 177–8°. Condensation of I with palmityl chloride in the presence of pyridine gave a mixt. of 2 products. The product, which was more difficultly sol. in petr. ether, was identified as *β-palmityl-α,α′-benzylideneglycerol* (II), m. 63.5°. The other more sol. substance was probably an isomeric form. Hydrogenation of II yielded *β-palmitylglycerol*, m. 69°. The latter may be converted back to II by condensation with BzH. Condensation of α-palmitin gave 63% of *α-palmityl-α′,β-benzylideneglycerol*, m. 35°. A similar condensation of β-palmitin with MeAc gave 75% of *β-palmityl-α,α′-isopropylideneglycerol*, m. 44°. When this condensation was performed

in the presence of HCl and Na_2SO_4 instead of $CuSO_4$ a rearrangement occurred with formation of 72% of α-palmityl-α′,β-isopropylideneglycerol, already described by Fischer, *et al.* (*C. A.* **15**, 684). A. W. Dox

Cobalt complexes of thioglycolic acid. Leonor Michaelis and Maxwell P. Schubert. *J. Am. Chem. Soc.* **52**, 4418–26(1930).—When a Co salt is mixed with a buffer around p_H 6–10 a pink ppt. is formed which is perfectly stable in air; the slightly sol. pink Co complex of pyrophosphate is not oxidized by air, in contrast to the analogous ferro complex. A mixt. of Co salt and phosphate buffer, contg. the slightly pink ppt., mixed with $SHCH_2CO_2H$ in a N atm. gives a green color, very sensitive in the air; on exposure to air, the soln. rapidly consumes O, simultaneously turning brown. In a mixt. of 1 atom of Co and 2 mols. $HSCH_2CO_2H$, 0.25 mol. of O is used with no, or no appreciable, residue of H_2O_2, during the first, rapid stage of the oxidation. A $HSCH_2CO_2K$ soln. and $CoCl_2$ in KH_2PO_4 and KOH give a deep red-brown color, from which the *salt*, $[Co(SCH_2CO_2)_2KH]_2.0.5H_2O$ (I), crystallizes in 75% yield. With $BaCl_2$ I gives the *salt*, $Ba[Co(SCH_2CO_2)_2H]_2.0.5H_2O$. I (15 g.) in 75 cc. H_2O, slowly treated with 3.5 cc. concd. HCl, gives the *acid K salt*, $KH[Co(SCH_2CO_2)_2H]_2.0.4H_2O$; with further addn. of HCl there results the free complex *acid*, $[Co(SCH_2CO_2H)_2]_2.0.3.5H_2O$. All of these complexes are quite stable and H_2S, KOH and $K_4Fe(CN)_6$ do not ppt. Co; they are also stable at 140° for a short time. The structure of these complexes is discussed. The bearing of these constitutions on the heavy metal catalysis of the oxidation of thio acids is pointed out. C. J. West

The behavior of polypeptides containing proline toward erepsin and the trypsin-kinase complex. Emil Abderhalden and Otto Zumstein. *Fermentforschung* **12**, 1–19(1930).—A series of dipeptides was prepd. in which proline carries the terminal CO_2H. The method consisted in coupling a haloacyl halide with *l*-proline and amination of the resulting haloacylproline with NH_4OH. A complication encountered was the formation of hydroxyacylprolinamide which had to be sepd. from the dipeptide, and also in some cases a racemization of the proline. The amt. of amide obtained increased with the size of the haloacyl halides used, *e. g.*, 5–7% with $ClCH_2COCl$, 13% with MeCHBrCOBr, 28–30% with EtCHBrCOBr, and 70–80% with $Me_2CHCH_2CHBrCOBr$. In contrast to other $Me_2CHCHBrCO$ amino acids, the proline deriv. was aminated with great ease, 71% of the Br being replaced in 2 days. When proline Me ester was condensed with haloacyl halide and the product aminated by alc. NH_3 both the expected anhydride and also the dipeptide ester were obtained. *l*-Proline in *N* NaOH was condensed with $ClCH_2COCl$ to form *chloroacetyl-l-proline*, m. 112–3°, which on amination with 25% NH_4OH yielded *glycolyl-l-prolinamide*, m. 90°, and *glycyl-l-proline*, $[\alpha]_D^{18}$ —86.21°. By the same procedure, proline + MeCHBrCOBr ⟶ *dl-α-bromopropionyl-l-proline* (I), m. 137–8°, ⟶ *dl-α-hydroxypropionyl-l-prolinamide*, m. 109–10°, *dl-alanyl-dl-proline*, m. 280° and *dl-alanyl-l-proline*, $[\alpha]_D^{18}$—92.68°. The Me ester of I + NH_3 in MeOH ⟶ *dl-alanyl-l-proline Me ester*, m. 89–93°, and *dl-alanyl-l-proline anhydride*, m. 114–5°, the anhydride and dipeptide ester occurring in the proportion 1:2. Proline + *dl*-EtCHBrCOBr ⟶ *dl-α-bromobutyryl-l-proline*, m. 120–3°, ⟶ *dl-α-hydroxybutyryl-l-prolinamide*, m. 76–8°, *dl-α-aminobutyryl-l-proline*, $[\alpha]_D^{18}$ —45.4°, and *dl-α-aminobutyryl-dl-prolinamide*, m. above 300°. Proline + *dl*-PrCHBrCOBr ⟶ *dl-α-bromovaleryl-l-proline*, m. 85–7°, ⟶ *dl-α-hydroxyvaleryl-l-prolinamide*, m. 60°, *dl-norvalyl-dl-proline*, m. 258–9°, and *dl-norvalyl-l-proline*, $[\alpha]_D^{18}$ —56.25°. Proline + *dl*-$Me_2CHCHBrCOBr$ ⟶ *dl-α-bromoisovaleryl-l-proline* (not obtained cryst.) *dl-α-hydroxyisovaleryl-l-prolinamide*, *dl-valyl-dl-proline*, m. 275°, and *dl-valyl-l-proline*, $[\alpha]_D^{18}$ —36.66°. Proline + BuCHBrCOBr ⟶ *dl-α-bromocaproyl-l-proline*, m. 69–70°, ⟶ *dl-α-hydroxycaproyl-l-prolinamide* (not purified), and *dl-norleucyl-l-proline*, m. 225–6°. Proline + $Me_2CHCH_2CHBrCOBr$ ⟶ *dl-α*-bromoisocaproyl-*l*-proline (II) (previously described) ⟶ *dl-α-hydroxyisocaproyl-l-prolinamide*, m. 124°, and *dl-leucyl-l-proline*, m. 211–2°. The Me ester of II treated with NH_3 in MeOH gave *dl-leucyl-l-proline Me ester* in 85% yield; an oily residue evidently consisted of a mixt. of amide and anhydride. These dipeptides and some of the amides and haloacylprolines were tested for enzymic hydrolysis. Trypsin-kinase attacked none of the dipeptides, and erepsin only glycylproline to a slight extent. Bromoisocaproyl-*l*-proline was hydrolyzed by trypsin-kinase, while bromopropionyl-*l*-proline remained unaltered. Neither enzyme attacked hydroxycaproyl-*l*-prolinamide. A. W. Dox

The behavior of *N* sodium hydroxide, erepsin and trypsin-kinase toward polypeptides built up from glycine. Emil Abderhalden and Jolan Heumann. *Fermentforschung* **12**, 42–54(1930).—A study of the hydrolysis of glycine peptides, from the

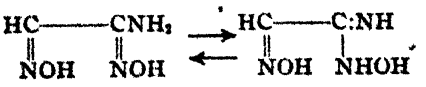
dipeptide to the hexapeptide inclusive, has already been reported (*C. A.* **22**, 426, 1572). The series has now been extended from there on to the decapeptide. The usual method of coupling the next lower peptide with $ClCH_2COCl$ and aminating the product was unsuccessful beyond the heptapeptide because of insoly. of the substance in dil. alkali. The difficulty was overcome by dispersing the peptide in 50% LiBr, then adding NaOH, dilg. with H_2O and finally adding the $ClCH_2COCl$. The $ClCH_2CO$ deriv. thus obtained was best aminated by mech. shaking of its suspension in liquid NH_3. New derivs. described are *chloroacetylpentaglycylglycine* (74% yield), sinters and becomes yellow at 225° *hexaglycylglycine* (84% yield), sinters above 230°. ⟶ *chloroacetylhexa-*[illegible] ⟶ *heptaglycylglycine* (74% yield) ⟶ *chloroacetylheptaglycylglycine* (74% yield) ⟶ *octaglycylglycine* (85% yield) ⟶ *chloroacetyloctaglycylglycine* (79% yield) ⟶ *nonaglycylglycine* (70% amination, but the product could not be completely purified). *β-Naphthalenesulfonylhexaglycylglycine* was obtained in 50% yield from the heptapeptide and β-$C_{10}H_7SO_2Cl$ in the usual manner. None of these higher peptides were attacked by erepsin at p_H 7.8, but the hexapeptide was partially hydrolyzed at p_H 8.4. All of the $ClCH_2CO$ derivs. were hydrolyzed to some extent by trypsin-kinase at p_H 7.8, but to a less extent, if at all, at p_H 8.4. The polypeptides were all resistant to trypsin-kinase. When dispersed in LiBr and brought to *N* by NaOH the rate of hydrolysis at 37° increased with increasing length of the peptide chain. The β-$C_{10}H_7SO_2$ deriv. was more resistant to alkali than the unsubstituted hexapeptide. A. W. Dox

Further comparative studies on the influence of *N* alkali, erepsin and trypsin-kinase on polypeptide-like compounds containing β-aminoisovaleric acid. Emil Abderhalden and Fritz Reich. *Fermentforschung* **12**, 20–41(1930).—Aside from the optical antipodes of naturally occurring amino acids, β-alanine is hitherto the only exotic amino acid that has been introduced into peptide chains for the purpose of testing the specificity of enzymes. A series of peptides has now been prepd. in which β-aminoisovaleric acid (I) represents the exotic component. This acid was prepd. by heating β,β-dimethylacrylic acid with a large excess of NH_4OH under pressure. It was coupled with various haloacyl halides and the products aminated in the usual way to the corresponding dipeptides, which were then built up further into polypeptides. Or, to place the exotic acid at the other end of the chain, the ordinary amino acids or their peptides were coupled with β-bromoisovaleryl chloride and the products aminated as usual. I + $ClCH_2COCl$ ⟶ *chloroacetyl-β-aminoisovaleric acid* (not obtained cryst.) ⟶ *glycyl-β-aminoisovaleric acid* (II), decomps. 210°. I + $Me_2CHCH_2CHBrCOCl$ ⟶ *dl-α-bromoisocaproyl-β-aminoisovaleric acid*, m. 104–5°, ⟶ *dl-leucyl-β-aminoisovaleric acid* (III), m. 195–8° (decompn.). III + $ClCH_2COCl$ ⟶ *chloroacetyl-dl-leucyl-β-aminoisovaleric acid*, m. 125–30°, ⟶ *glycyl-dl-leucyl-β-aminoisovaleric acid*, m. 200°. II + $Me_2CHCH_2CHBrCOCl$ ⟶ *dl-α-bromoisocaproylglycyl-β-aminoisovaleric acid* (not crystd.) ⟶ *dl-leucylglycyl-β-aminoisovaleric acid*, decomps. 225°, ⟶ *chloroacetyl-dl-leucylglycyl-β-aminoisovaleric acid*, m. 170°, ⟶ *glycyl-dl-leucylglycyl-β-aminoisovaleric acid* (IV), sinters 165° and decomps. 175°, ⟶ *dl-α-bromoisovaleryl-glycyl-dl-leucylglycyl-β-aminoisovaleric acid*, a viscous oil, ⟶ *dl-valylglycyl-dl-leucyl-glycyl-β-aminoisovaleric acid*, m. 193–8° (decompn.). *β-Bromoisovaleryl chloride* (V), b_{20} 60–2°, was prepd. by satg. $Me_2C{:}CHCO_2H$ with HBr to $Me_2CBrCH_2CO_2H$ and treatment of the latter with $SOCl_2$. V + *dl* leucylglycine ⟶ *β-bromoisovaleryl-dl-leucylglycine*, sinters 105° and m. 120°, ⟶ *β-aminoisovaleryl-dl-leucylglycine* (VI), m. 125°. V + *dl*-leucylglycyl-*dl*-leucine ⟶ *β-bromoisovaleryl-dl-leucylglycyl-dl-leucine*, sinters 100° and m. 145°, ⟶ *β-aminoisovaleryl-dl-leucylglycyl-dl-leucine*, m. 125–30° (foaming). V + IV ⟶ *β-bromoisovalerylglycyl-dl-leucylglycyl-β-aminoisovaleric acid*, m. 112–4°, ⟶ *β-aminoisovalerylglycyl-dl-leucylglycyl-β-aminoisovaleric acid* (VII), sinters 180° and m. 185° (evolution of gas). $Me_2CHCH_2CHBrCOCl$ + VI ⟶ *dl-α-bromoisocaproyl-β-aminoisovaleryl-dl-leucylglycine*, an oil, ⟶ *dl-leucyl-β-aminoisovaleryl-dl-leucylglycine*, sinters 230° and decomps. 245°. Enzyme expts. showed that β-aminoisovaleric acid inhibited the action of amino- or carboxy-polypeptidase according to whether it was linked through its NH_2 or CO_2H to the polypeptide chain. The expectation that VII, because of its analogy to *d*-leucylglycyl-*l*-leucylglycyl-*d*-leucine, would be amenable to hydrolysis by the trypsin complex was not fulfilled. Such hydrolysis would support the assumption of an imino-polypeptidase capable of attacking a polypeptide at an intermediate linkage. It is possible that different exotic components may offer different degrees of resistance, or that the enzyme-substrate compd. may be so stable that the usual H ion concn. is inadequate for hydrolysis. Erepsin was inert toward all of these peptides. Trypsin-kinase attacked the 2 tetrapeptides in which the terminal CO_2H was on leucine and glycine, resp. All

were partially hydrolyzed by *N* NaOH, except the dipeptide *dl*-leucyl-β-aminoisovaleric acid. A. W. Dox

The preparation of propylalanine and of propylpeptides in general. Max Frankel and Sonja Kuk. *Biochem. Z.* **226**, 221–32(1930).—For the details of the prepn. by way of Br derivs. the original paper must be consulted. S. Morgulis

Reduction of *l*-cystine to *l*-cysteine. Erich Gebauer-Fuelnegg. *J. Am. Chem. Soc.* **52**, 4610–1(1930).—A brief outline is given for the reduction of *l*-cystine in CO_2-free H_2O and 1–1.5 times its wt. of Al-Hg. C. J. West



Reduction of cystine in liquid ammonia by metallic sodium. Vincent du Vigneaud, L. F. Audrieth and H. S. Loring. *J. Am. Chem. Soc.* **52**, 4500–4(1930).—Cystine is sol. in liquid NH_3 and can be reduced readily by Na in this medium to cysteine. Details of the reduction and isolation of the base are reported. Benzylcysteine may be prepd. by adding $PhCH_2Cl$ directly to the liquid NH_3 soln. of the reduction product. Four atoms of Na are required to reduce 1 mol. of cystine. C. J. West

Dioximes. LXIV. G. Ponzio and F. Baldracco. *Gazz. chim. ital.* **60**, 415–29 (1930); cf. *C. A.* **24**, 3774.—Because of the uncertainty which has existed for many yrs. regarding the structure of α- and β-chloroglyoxime (I and II, resp.), expts. were undertaken by P. and B. to throw further light on the problem The results show that it is impossible to assign to I and II configurations which are in accord with the theory of Hantzsch and Werner. The results, moreover, confirm the conclusions of earlier expts. (cf. *C. A.* **24**, 3488). I was prepd. by modifying the method of Hantzsch (cf. *Ber.* **25**, 705(1892)) so that a 50% yield was obtained. Chloral hydrate (50 g.), added to very concd. aq. $NH_2OH.HCl$ (63 g.) and Na_2CO_3 (48 g.), let stand 4–5 hrs., made ice-cold, aq. NaOH (54 g. in 100 cc.) added, acidified with concd. H_2SO_4, dild. with water, made alk. with NH_4OH, 20% aq. $Ni(OAc)_2$ added until pptn. is complete (avoiding excess), filtered, the ppt. treated with H_2SO_4, extd. with Et_2O, the Et_2O eliminated from the ext., and the residue recrystd. from water, yields I. I, dissolved in a little HCl and Et_2O, let stand, evapd. and the residue recrystd. from xylene, yields 100% of II, m. 168° (decompn.) (cf. 161° of Hantzsch, *loc. cit.* and 164–74° of Steinkopf, *C. A.* **4**, 2277; **5**, 3234). Contrary to Atack (*C. A.* **7**, 3291) and to Hieber and Leutert (*C. A.* **23**, 4692), aq. $Ni(OAc)_2$ and aq. II in the presence of HOAc do not form a ppt. but only a green soln., whereas all other β-glyoximes (considered by supporters of the Hantzsch and Werner theory as *anti*-forms and by Chugaev as *syn*-forms) form complex salts of the type $(DH)_2Ni$, insol. in dil. AcOH. In the absence of AcOH, the green liquid becomes brown red, then turbid, evolves HCN and finally ppts. a small quantity of brown-yellow flocculent ppt., while the liquid contains the Cl ion. A mixt. of alc II and alc. $Ni(OAc)_2$ is green at first, and becomes brown-red after several hrs., but does not form a ppt. even on dilu. with water. Treatment of aq. II with Br forms *chlorobromoglyoxime*, $ClC(:NOH)C(:NOH)Br$, which will be described in a forthcoming paper. NH_3 passed into alc. II, evapd., the residue heated with C_6H_6, and the filtered ext. cooled, ppts. $HC(:NOH)C(:NOH)NH_2$ (III) (cf. Steinkopf, *C. A.* **4**, 2277). II, agitated with NaOAc in 50% AcOH and the product isolated by treatment with $Ni(OAc)_2$ and NH_4OH, yields $HC(:NOH)C(:NOH)OH$ (cf. *C. A.* **21**, 1097). II and BzCl (calcd. proportions), heated for some time at 100° and the product recrystd. from $CHCl_3$, yields *β-2-benzoylchloroglyoxime*, $HC(:NOBz)C(:NOH)Cl$ (IV), m. 165°. IV in Et_2O and 5% aq. Na_2CO_3 ppts. $HC(:NOBz)C_7N_2O_2C(:NOBz)H$ (cf. Wieland, *C. A.* **19**, 2807; Steinkopf, *C. A.* **4**, 2277), which is also formed in smaller yield by heating IV in water at 100°. This reaction is then analogous to that between $MeC(:NOH)C(:NOH)Cl$ and BzCl (cf. Avogadro and Vianello, *C. A.* **21**, 1099). IV, Ac_2O and NaOAc yield, after crystn. of the product from EtOH, *β-2-benzoyl-1-acetylchloroglyoxime*, $HC(:NOBz)C(:NOAc)Cl$, m. 120°. IV, heated with excess BzCl at 100° and the product crystd from EtOH, yields β-$HC(:NOBz)C(:NOBz)Cl$ (V), m. 165° (cf. Wieland and Kitasato, *C. A.* **2**, 4674). V is also formed by prolonged heating of II with excess BzCl and recrystg. from glacial AcOH, or by isomerization of α-dibenzoylchloroglyoxime (VI) in anhyd. Et_2O by HCl in Et_2O. A method of prepn. of VI better than that of Wieland and Kitasato (*loc. cit.*) is to dissolve I (5 g.) in water (100 cc.) contg. a little AcMe, add BzCl (16.5 g.), make ice-cold, add 10% NaOH (100 g.) and recrystallize from EtOH or glacial AcOH. W. and K. report that V is decompd. by cold alc. KOH, with liberation of Cl ions. However, NH_3 passed through ice-cold V in EtOAc ppts. NH_4Cl and leaves III in soln., which shows substitution of Cl and complete hydrolysis On the other hand, V in EtOAc agitated with a little 6 *N* NH_4OH forms *β-2-benzoylaminoglyoxime*, $HC(:NOBz)C(:NOH)NH_2$ (VII), showing substitution with only partial hydrolysis. VII is more readily prepd. by agitating IV in Et_2O with 6 *N* NH_4OH, washing with water, eliminating the solvent and recrystg.

from dil. EtOH. It m. 157–8°, and in EtOH it gives a brown-red color with $FeCl_3$. VII and Ac_2O yield, after crystn. of the product from dil. EtOH, *β-1-acetyl-2-benzoyl-aminoglyoxime*, $HC(:NOBz)C(:NOAc)NH_2$, m. 145–6° (softening a few degrees below). LXV. G. Ponzio. *Ibid* 429–36.—The expts. complete the intended study of halogeno- [illegible] The for-

NH_4OH is analogous to the formation of [illegible] (:NOH)C(:NOMe)Me (cf. Thilo, *C. A.* **23**, 3902) and both of these reactions are in turn analogous to the formation of MeC(:NOBz)C(:NOBz)Me from MeC(:NOBz)Ac (cf. Diels and Stern, *C. A.* **1**, 1987). In a forthcoming paper will be discussed the kinetics of the reaction: $2RC(:NOH)COR' \longrightarrow RC(:NOH)C(:NOH)R' + RCOCOR'$, which represents a new method of formation of glyoximes, of great importance in connection with the theory of Hantzsch and Werner. MeC(:NOH)C(:NOH)Cl, treated with cold Ac_2O or heated with AcCl and the product recrystd. from EtOH, yields *diacetylmethylchloroglyoxime* MeC(:NOAc)C(:NOAc)Cl, m. 129°; treated in ice-cold AcOEt with NH_3 gas it forms NH_4Cl and MeC(:NOH)C(:NOH)NH_2 (cf. *C. A.* **16**, 2676). According to the literature, $MeC(:NOH)C_2N_2O_2C(:NOH)Me$ (I) has 3 isomeric forms (cf. *Ann.* **277**, 327(1893); **238**, 231(1894); **309**, 241(1899); **310**, 246 (1899); **328**, 214(1903); P., *C. A.* **18**, 661), and if, as is probable, the 1st isomer (the compd. of Tryller, cf. *Ann.* **310**, 246(1899)) is identical with the diacetylglyoxime peroxide dioxime of P., the same phenomenon observed with $HC(:NOH)C_2N_2O_2C(:NOH)H$ (II) is true of I. The isomer of II is attributed by Wieland (who considers $R(C_2N_2O_2)R$ peroxides as $R[O(C_2N_2O)]R$ furoxans) to the different spatial position of the oximic OH, but it is not impossible that it may be due to a difference in the structure of the $C_2N_2O_2$ group. The problem is of importance for the constitution of peroxides which, in spite of Wieland, is not yet explained. Further work on this subject is promised. To complete the series of halogen derivs. of HC(:NOH)C(:NOH)H, Br (calcd. quantity) was agitated with aq. HC(:NOH)C(:NOH)Cl (cf. above), let stand, and the ppt. recrystd. from a mixt. of Et_2O and petr. ether, which yields *chlorobromoglyoxime*, ClC(:NOH)C(:NOH)Br (III), m. 222–3° (decompn.), partially decompd. by boiling water. III reacts in water with $PhNH_2$ with formation of PhNHC(:NOH)C(:NOH)NHPh (cf. Wieland, *C. A.* **4**, 329). Dissolved in Ac_2O and the excess of the latter evapd. *in vacuo* over KOH, III forms a *di-Ac deriv.*, ClC(:NOAc)C(:NOAc)Br, which, recrystd. from EtOH, m. 160–1°. A method of prepn. of ClC(:NOH)C(:NOH)Cl (IV) more convenient than that of Steinkopf and Jurgens, (*C. A.* **5**, 3234) or Houben and Kauffman (*C. A.* **8**, 111) is to pass Cl through ice-cold glyoxime (5 g.) in 10% HCl (150 cc.) until permanently yellow, and let stand 12 hrs., which ppts. 5 g. of IV. Houben and Kauffmann (cf. *C. A.* **8**, 111) prepd. ClC(:NOBz)C(:NOBz)Cl (V) from IV, and from V they prepd. a compd. (VI) with the same m. p. as $H_2NC(:NOH)C(:NOH)NH_2$ (VII), but from this latter they could not obtain a di-Bz deriv., so they concluded that VI was not VII but a spatial isomer of the ordinary form of VII. The expts. of P., however, show that the diaminoglyoxime obtained by the action of NH_3 on the di-Ac deriv. of IV is chem. and phys. identical with VII prepd. by the method of Fisher (*Ber.* **22**, 1931(1889)). The errors in the expts. of H. and K. (*loc. cit.*) arise from the peculiar behavior of VII toward Ac_2O. If VII is dissolved in boiling Ac_2O and the soln. cooled immediately, VII crystallizes unaltered, and only by boiling 10 min. and pouring in water is the di-Ac deriv. obtained. Prolonged heating forms oxalenediazoöximediethenyl, $Me(C_2N_2O)_2Me$, whose formation is complete in 24 hrs. This last compd. cannot be isolated by the methods described in the literature, and it is necessary to pour the reaction product into water, neutralize with Na_2CO_3, ext. with $CHCl_3$, evap., wash the residue with Et_2O and recrystallize from boiling water, which gives a product, m. 165–6°. LXVI. G. Ponzio and E. Durio. *Ibid* 436–48.—The expts. which deal with acyl derivs. of $HC(:NOH)C(:NOH)NH_2$ (I), show that it is impossible to assign to I a configuration which is in accord with the theory of Hantzsch and Werner. I was prepd. by Steinkopf (*C. A.* **4**, 2277) and S. and Bohrmann, (*C. A.* **1**, 1979), but was not obtained pure. It can, however, be purified by dissolving in Et_2O, pptg. with HCl gas, decompg. the HCl salt with NH_4OH and crystg. from water. Thus obtained, it has the *compn.* $C_2H_5O_2N_3.H_2O$, loses water slowly on exposure to air or rapidly at 40–50°, and the anhydride m. 145.5° (decompn.). In aq. soln. with $Ni(OAc)_2$ it forms the *complex salt*, $C_4H_8O_4N_6Ni$, bright red. $(CO_2H)_2$ in Et_2O added to I in Et_2O ppts. the *oxalate* of I, $HC(:NOH)C(:NOH)NH_2.H_2C_2O_4$, m. 159°. Concd. HCl and KOCN, added to aq. I, let stand and the ppt. recrystd. from water yield, *ureidoglyoxime*, $HC(:NOH)C(:NOH)NHCONH_2$, m. 157° (decompn.), does not form a Ni salt. HC(:NOBz)C(:NOH)Cl in Et_2O agitated with N[illegible]

forms $HC(:NOBz)C(:NOH)NH_2$ (II) (cf. above), and in a similar way was prepd. $HC(:NOBz)C(:NOBz)NH_2$ (III), also described previously (same reference). I, benzoylated by the method of Jacobs and Heidelberger (*C. A.* **11**, 2329), *i. e.*, I (4 g.) in glacial AcOH (30 cc.) treated with satd. aq. AcONa (30 cc.) and then, after making ice-cold, with BzCl (6.5 g.), and the product crystd. from boiling water, forms the *1-Bz deriv.* of I, $HC(:NOH)C(:NOBz)NH_2.H_2O$ (IV), m. 134–7°, loses its water *in vacuo;* the *anhydride* m. 146–7°; does not give any color with $FeCl_3$. III and cold Ac_2O yield, after crystn. of the product from EtOH, *1-benzoyl-2-acetylaminoglyoxime*, $HC(:NOAc)C(:NOBz)NH_2$ (V), m. 166–7°. BzCl (3.6 g.), added dropwise to I (1 g.) in 10% NaOH (11.5 cc.) and the product recrystd. from EtOH or C_6H_6, yields the *di-Bz deriv.* of I, m. 186–7°, also formed by adding BzCl to II or IV and then adding dropwise concd. AcONa. IV, Ac_2O and a little AcONa, refluxed gently for a short time, water added, steam-distd. and the product recrystd. from EtOH, yields *3-cyano-5-phenylazoxime* (*3-cyano-5-phenylfuro(ab$_1$)diazole*), $\overset{\frown}{NCC:N.O.CPh:N}$ (VI), m. 62°. It is also formed similarly from III or V and Ac_2O. Alc. VI (1 mol.) and alc. Na (1 atom) heated 3–4 hrs. at 100°, evapd., the residue (a mixt. of $H_2NCO(C_2N_2O)Ph$ (see later) and NCNNaBz) treated with water, filtered, the filtrate acidified with H_2SO_4, and the ppt. recrystd. from EtOH, yields NCNHBz (VII). The formation of VII from VI confirms the structure of VI, and the reaction is analogous to that of Boeseken and van Lennep with 3-acyl-5-arylaminoazoximes (cf. *Rec. trav. chim.* **31**, 1961(1912)). It is explained by assuming that the acid is first formed: VI + $2H_2O$ ⟶ $\overset{\frown}{HO_2CC:N.O.CPh:N}$ (VIII) + NH_3; VIII then loses CO_2: VIII $\xrightarrow{-CO_2}$ $\overset{\frown}{HC:N.O.CPh:N}$, and the latter, like all mono-substituted azoximes, is unstable and isomerizes to VII. The *compd.* $H_2NCO(C_2N_2O)Ph$, to be described later, is a secondary intermediate product. VI, let stand several days with HCl (d. 1.19), dild. with water, filtered, the residue freed of unaltered VI by steam distn. and the residue recrystd. from boiling EtOH, yields *3-carboxy-5-phenylazoximeamide*, $H_2NCO(C_2N_2O)Ph$, m. 159–60°; heated with alc. Na it evolves NH_3 and CO_2 and forms NCNNaBz. H_2S, passed into alc. VI at 50–60°, dild. with water, and the product recrystd. from $CHCl_3$, yields *3-carboxy-5-phenylazoximethioamide*, $H_2NCS(C_2N_2O)Ph$, yellow, m. 171–2° (decompn.). Prepd. by the method of Houben and Kauffmann (*C. A.* **8**, 111), $HC(:NOAc)C(:NOAc)NH_2$, m. 82° (not 70–2° as reported by H. and K.), decompd. to I by cold aq. NaOH. Prepd. by the method of Steinkopf (*C. A.* **4**, 2277) or more simply by treating I with Ac_2O and AcONa, pouring into water and recrystg. from water, $HC(:NOAc)C(:NOH)NHAc$ (IX), m. 154° (not 142–50° as reported by S.). Contrary to S., it does not in water give any color with $FeCl_3$, but the color appears if it is heated in water, as a result of hydrolysis. IX (5 g.) and 20% aq. NaOH (20 cc.), heated gently, dild. with water, acidified with HCl and the product recrystd. from water or EtOH, yields *N-acetylcyanoformamidoxime*, NCC(:NOH)NHAc (X), m. 186°. The formation of X from IX is explained on the assumption that the reaction is analogous to that of the formation of PhC(:NOAc)C(:NOH)NHAc (cf. *C. A.* **17**, 3875), *i. e.*, AcOH is first eliminated from IX, forming $\overset{\frown}{HC:N.O.N:CNHAc}$, and the latter isomerizes (like all mono-substituted furazans) to X. Benzoylation of X in 10% NaOH, with crystn. of the product from EtOH, yields *N-acetyl-O-benzoylcyanoformamidoxime*, NCC(:NOBz)NHAc, m. 149°. A discussion of the reactions involved in these various syntheses shows the contradictions which arise if the attempt is made to assign any kind of configuration to I, the inadequacy of the theory of Hantzsch and Werner, and the necessity of substitution for this theory some less general one. The properties of I can be explained only by a tautomerism between the 2 dioximic and oximinohydroxyamidinic formulas, which is represented by the equil.:

C. C. Davis

Alcoholysis of certain 1,3-diketones and β-ketonic esters. Walter M. Kutz and Homer Adkins. *J. Am. Chem. Soc.* **52**, 4391–9(1930); cf. *C. A.* **24**, 5722.—The amt. of $AcCH_2CO_2Et$ to be obtained from the reaction mixt. is the same irrespective of whether it is synthesized from AcOEt and EtONa or remains from the alcoholysis of $AcCH_2CO_2Et$ mol. equiv. to the amt. of EtONa used in the synthetic reaction. All attempts to make similar detns. on the synthesis and alcoholysis of 1,3-diketones

have failed because no conditions have been found under which homogeneity would be maintained during the synthesis and alcoholysis. The rates of alcoholysis at 60° of CH_2Ac_2, CH_2AcBz, $PhCH_2CHAc_2$, $EtCHAc_2$, $(PhCH_2)_2CAc_2$, $PhCH_2CHAcBz$, $AcCH_2CO_2Et$, $AcCHEtCO_2Et$, $AcCH(CH_2Ph)CO_2Et$, $AcCEt_2CO_2Et$ and $AcC(CH_2Ph)_2CO_2Et$ were detd. in the presence of various ratios of EtONa. The keto esters were found to be more stable than the diketones toward alcoholysis for a given ratio of EtONa. Substitution on the C atom between the 2 CO groups very considerably increased the rate of alcoholysis in the presence of EtONa. This effect reached its max. in the case of the diacyldialkylmethanes, which underwent alcoholysis hundreds of times as rapidly as the diacylmethanes. When the 6 diketones whose reactivity was measured in the presence of both HCl and EtONa were arranged in the order of decreasing reactivity with respect to alcoholysis in the presence of HCl, they were found to be arranged (with 1 exception) in the order of increasing reactivity toward alcoholysis in the presence of EtONa. Et_2CBz_2, which is incapable of enolization, readily underwent alk. alcoholysis and hydrolysis. These facts taken in conjunction with the parallelism between the extent of enolization and rate of acid alcoholysis offer support to the hypothesis of Bradley and Robinson that alk. cleavage of 1,3-diketones takes place through the reaction of the CO rather than of the enol form of the diketone. C. J. West

Course of addition of sodium enol alkyl malonic esters to α,β-unsaturated esters. Arthur Michael and John Ross. *J. Am. Chem. Soc.* **52**, 4598–609(1930); cf. *J. prakt. Chem.* 35, 349(1887); 37, 496(1888).—The course of addn. of $CHMe(CO_2Et)_2$ to crotonic and cinnamic esters varies with the amt. of EtONa used. In the presence of small amts. of EtONa the addn. proceeds with H and $-CMe(CO_2Et)_2$ as addendum components. In the presence of a mol. equiv. of EtONa the addn. proceeds with Me and $-C(CO_2Et):C(ONa)OEt$ as addendum components. These results rigorously prove the correctness of Thorpe's conclusions (*J. Chem. Soc.* **77**, 923(1900)) that the addn. of $NCCH:C(ONa)OEt$ to $CH_2:CMeCO_2Et$ takes place with migration of the H atom and that the addn. of $MeC(CN):C(ONa)OEt$ to $Me_2C:CHCO_2Et$ takes place with the migration of the Me group. The original should be consulted for the mechanism of these reactions and explanations of the results. Condensation of $CHNa(CO_2Et)_2$, $[EtO_2CCH:C(ONa)OEt]$ and $MeCH:CHCO_2Et$ with a small amt. of EtONa gives *95%* of the Et ester, b_2 144°, of *β-methyl-γ-carboxyglutaric acid*, m. 139°; the Et ester in EtONa and EtOH gives with MeI the Et ester, b_2 160°, of $MeCH[CMe(CO_2H)_2]CH_2CO_2H$, m. 167° (Thorpe and Young, *J. Chem. Soc.* **83**, 358(1903)); further attempts to methylate the ester caused only cleavage into $MeCH:CHCO_2Et$ and $CMeNa(CO_2Et)_2$. The enol form of $CMeNa(CO_2Et)_2$ and $MeCH:CHCO_2Et$, condensed with 1/6 mol. EtONa, give an Et ester, b_2 155°, sapon. to a mixt. of approx. 90% β,γ- and 10% *α,β-dimethyl-γ-carboxyglutaric acids* (I); using 1 mol. equiv. of EtONa the main product was the *Et ester*, b_2 148–50°, of I, m. 145°; distn. of I gives a mixt. of *cis-* and *trans*-dimethylglutaric acids. Distn. of the β,γ-acid gives the same products. Further methylation of the Et ester of I gives the *α,β,γ-tri-Me deriv.*, b_2 164°; the free *acid* (II) did not crystallize. The action of EtONa upon the Et ester of the β,γ-acid causes some cleavage and also gives the Et ester of I. I was also formed by the addn. of $CHNa(CO_2Et)_2$ to Et tiglate; larger quantities were prepd. by the use of $NCCHNaCO_2Et$. Et α,β-dimethyl-γ-cyanoglutarate and EtONa, treated with MeI, give the *Et ester*, b_2 160°, of α,β,γ-trimethyl-γ-cyanoglutarate; hydrolysis gives II. Heating at 160° for 30 min. splits off CO_2, giving a mixt. of the *cis-* (III) and *trans-*forms (IV) of α,β,γ-trimethylglutaric acid; III, m. 125°, was sepd. by conversion into the anhydride and then into the *imide*, m. 90°; IV could not be crystd. *β-Phenyl-γ-carboxyglutaric acid* m. 137°; methylation of the Et ester in EtONa in Et_2O gives a mixt. of cleavage products and also the *Et ester* (IV), b_2 194°, of *γ-methyl-β-phenyl-γ-carboxyglutaric acid*, m. 188° (decompn.) and 148°, on standing several days the lower-melting changing into the higher-melting form. Condensation of $CMeNa(CO_2Et)_2$ and $PhCH:CHCO_2Et$ with a small amt. of EtONa gives V; with 1 mol. equiv. of EtONa there results the *Et ester*, b_2 185–8°, of *α-methyl-β-phenyl-γ-carboxyglutaric acid*, which exists in 2 forms, m. 171° and 145°; these were also obtained by hydrolysis of *Et α-methyl-β-phenyl-γ-cyanoglutarate*, b_2 185–7°, obtained from $PhCH:CMeCO_2Et$ and $NCCHNaCO_2Et$. C. J. West

Thermal data on organic compounds. IX. Study of the effect of unsaturation on the heat capacities, entropies and free energies of some hydrocarbons and other compounds. George S. Parks and Hugh M. Huffman. *J. Am. Chem. Soc.* **52**, 4381–91(1930); cf. *C. A.* **24**, 4755.—Data on the specific heats are given for fumaric, maleic and succinic acids, 2-pentene, trimethylethylene (I), pentane (II), cyclohexene

(III), methylcyclohexane (IV), diisobutylene (V), stilbene, dibenzoylethylene and dibenzoylethane. The heats of fusion were detd. as follows: I, m. 138.9°K, 25.74 cal. per g.; II, m. 143.4°K, 27.75; III, m. 169°K, 9.57; IV, m. 146.2°K, 16.24; V, m. 172°K, 16.83. III has a transition temp. of 138.7°K, the heat of transition being 11.86 cal. per g. The entropies of 11 of the compds. have been calcd. from these heat-capacity data. In general the entropy of an unsatd. substance was found to be slightly less than that of the corresponding satd. compd. The corresponding free energies have also been calcd. The free-energy change in dehydrogenation reactions was found to vary greatly and it is apparent that the effect of unsatn. in detg. the free energy value of an org. compd. is very sp. C. J. WEST

Carbon dioxide cleavage of pyruvic acid. I. Preliminary experiments. UNO BOKLUND. *Biochem. Z.* **226**, 56–61(1930).—$AcCO_2H$ can be decompd. into CO_2 and AcH, this reaction being catalyzed by various NH_2 compds. This decarboxylation takes place even in dil. aq. solns. at room temp. The H-ion concn. is very important in detg. the degree of catalysis, the NH_2 compds. having a very definite p_H optimum for their activity. This reaction is in many respects similar to the enzymic decarboxylation of $AcCO_2H$. S. MORGULIS

Influence of hydrogen ions on the Fenton reaction. W. H. HATCHER AND M. G. STURROCK. *Can. J. Research* **3**, 214–23(1930).—By means of cond. measurements of the reaction mixt. when tartaric acid is oxidized by H_2O_2 in the presence of $FeSO_4$ as catalyst the course of the reaction was followed. Conclusion: The very small yields of dihydroxymalcic acid result from the inactivation of the catalyst by the relatively strong acid formed. Rearrangement to an isomer of dihydroxymaleic acid prevents quant. sepn. The existence of the tautomeric keto form of dihydroxymaleic acid was clearly indicated. The yield of dihydroxymaleic acid will be increased in this reaction when some compd. is found which will reduce the $\left[\overset{+}{H}\right]$ and at the same time shift the equil. in favor of the enol form. J. W. SHIPLEY

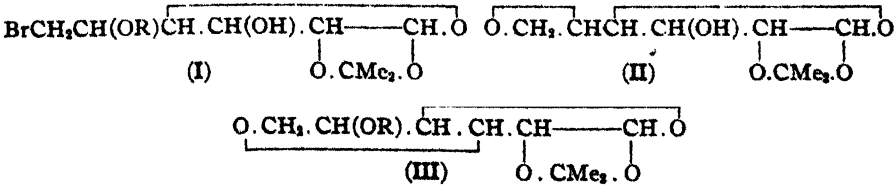
Direction of addition of hydrogen bromide to α-methyleneglutaric acid. JOHN WM. BAKER. *Proc. Leeds Phil. and Lit. Soc. Sci. Sect.* **2**, 115–9(1930).—By addn. of HBr to α-methyleneglutaric acid von Pechmann and Röhm in 1901 obtained a Br acid which on reduction gave α-methylglutaric acid. It was not detd. whether the Br was attached to the α-C forming α-bromo-α-methylglutaric acid (I), or in the Me group forming α-bromomethylglutaric acid (II). According to the theory of Burton and Ingold (*C. A.* **22**, 2556) II should be correct. Baker attempted to make I by direct methods. By boiling γ-cyano-γ-valerolactone with abs. EtOH satd. with HBr a good yield was obtained of Et α-hydroxy-α-methylglutarate (III), b_8 115°, n_D^{20} 1.4375. III was also prepd. by treating crude Et γ-cyano-γ-hydroxyvalerate in similar manner and also by the action of EtI on Ag α-hydroxy-α-methylglutarate. By bromination of III by PBr_5 in benzene a Br-ester was obtained which when distd., even under reduced pressure, rapidly eliminated EtBr, leaving the lactonic ester (IV) $MeC(CO_2Et).CH_2.CH_2.CO.O$, b. 265°, b_{14} 142°. IV was also formed from III by distg. twice at atm. pressure. By hydrolysis of III or IV the lactonic acid, m. 73°, was prepd. B. concludes I is too unstable to be prepd. and that the acid of von P. and R. must have been II. L. E. GILSON

Urea formation. I. Urea formation from amino acids through catalytic oxidation on carbon. MINORI ARAI. *Biochem. Z.* **226**, 233–6(1930).—Glycocoll, alanine, asparagine, glutaminic acid, phenylalanine and arginine, as well as glycylglycine, glycine and phenylalanine anhydrides are oxidized in the presence of O_2 to urea by shaking with C for a long time. To demonstrate the urea as the dixanthylurea ppt. the mixt. must be first heated to 100° with 1 cc. 10% $(NH_4)_2SO_4$. If the expt. is carried out in the presence of NH_4OH the ppt. of urea is obtained directly with a no. of amino acids, but an extra amt. is also formed after heating with the $(NH_4)_2SO_4$. The effect of the NH_4OH is not due to the OH-ions as this is not obtainable with NaOH. S. MORGULIS

Thermal requirements and operating characteristics of the urea autoclave. K. G. CLARK AND V. L. GADDY. *Ind. Eng. Chem.* **22**, 1084–77(1930). Cf. Krase, Gaddy and Clark, *C. A.* **24**, 2111.—From the thermal requirements under operative and non-operative conditions the heat of reaction of $2NH_3$ and CO_2 to form a kg. of urea was found to be 128.2 ± 8.7 kg.-cal. at 36.5% conversion. High Si-Cr-Ni steels resisted corrosion in the autoclave. L. P. HALL

Pyrimidines. CXVI. An improved technic for the synthesis of *N*-alkyl derivatives of thymine. TREAT B. JOHNSON. *Ber.* **63B**, 1974–6(1930).—Bachstez (*C. A.* **24**, 3760), in establishing the identity of orotic acid (I) with Wheeler's uracil-4-carboxylic

acid (II) by comparison of characteristic derivs. of I, used certain alkyl derivs. which he prepd. in different ways. Esterification with MeOH and EtOH yielded the corresponding normal esters, but treatment of the Ag salt with alkyl halides gave entirely different products which he assumed to be *N*-derivs. He describes no expt., however, which is contrary to the assumption that these alkyl derivs. are imido esters of the type NH.CO.N:C(OMe).CH:CCO_2H. It has been found in J.'s lab. that pyrimidines with alkoxy groups may show wide variations in stability; some are readily isomerized by heat or by the action of alkyl halides into *N*-alkyl isomers (cf. Hilbert and J., *C. A.* **24**, 3016). Schmidt-Nickels and J. (following abstr.) have made a similar observation on thymine derivs. The reaction is useful in prepg. alkyl derivs. of known structure and may aid in establishing the constitution of the derivs. of I prepd. by B. C. A. R.



Pyrimidines. CXVII. Method for the synthesis of nucleosides. G. E. Hilbert and T. B. Johnson. *J. Am. Chem. Soc* **52**, 4489–94(1930); cf. preceding abstr.—2,6-Dimethoxypyrimidine and acetobromoglucose, heated at 50° for 48 hrs., give 3-methyluracil and 23–32% of *2-keto-6-methoxy-3-(tetraacetylglucosido)pyrimidine* (I), m. 220–1°; at room temp. the yield after 2 weeks is only 5%; at 80° the crystn. starts in a few hrs. but the yield is only 9%; if equiv. amts. of the reactants are used the yield is not only very poor but the product is difficult to obtain pure. I in abs. MeOH and dry HCl in abs. EtOH give 97% of *3-glucosidouracil* (II), crystg. with 0.5 mol. H_2O, m. 207–9° (decompn.); $[\alpha]_D^{23}$ 21.4° (H_2O); it does not reduce Fehling soln. after boiling with HCl; Ac_2O and AcONa give the *tetra-Ac deriv.*, m. 154–5°. II and Br-H_2O give the *5-Br deriv.*, decomps. 238°, $[\alpha]_D^{25}$ 10.3° (H_2O). Catalytic reduction of II gives the *4,5-dihydro deriv.* (III), decomps. 238°, $[\alpha]_D^{24}$ 9.3° (H_2O); hydrolysis gives 4,5-dihydrouracil and glucose. Since II is not hydrolyzed by dil. acid and III is, their behavior is similar to uridine and its 4,5-dihydro deriv.; this is believed to be the strongest direct exptl. evidence yet obtained in favor of the structure of uridine being 3-ribosidouracil. **CXVIII. Molecular rearrangements in the thymine series.** W. Schmidt-Nickels and T. B. Johnson. *Ibid* 4511–6.—2,6-Dichloro-5-methylpyrimidine, m. 25–6°, and EtONa give the *2,6-di-MeO deriv.* (I), m. 61°; heating at 200° for 48 hrs. causes rearrangement into 1,3-dimethylthymine, m. 155°. I and MeI at room temp. give *2-keto-3,5-dimethyl-6-methoxypyrimidine*, m. 144°; warming with HCl gives quant. 3-methylthymine, m. 291°. *2,6-Diethoxy-5-methylpyrimidine* (II), m. 36°, is stable when heated at 200° for 48 hrs.; with MeI there results *2-keto-3,5-dimethyl-6-ethoxypyrimidine*, m. 111°, converted by dil. HCl to 3-methylthymine; with EtI there results the corresponding *3-ethyl-5-methyl deriv.*, m. 78°, and yielding with dil. HCl *3-ethylthymine*, m. 223°; Et-Br could not replace EtI. I and bromoacetoglucose give 3-methylthymine. Chloroacetoglucose does not react with I or II. II and bromoacetoglucose give a compd., m. 316°, which was not further examd. C. J. West

Rhamnose (mannomethylose) derivatives. E. Votoček, F. Valentin and F. Rac. *Collection Czechoslov. Chem. Communications* **2**, 402–13(1930); cf. *C. A.* **23**, 2719.—Anhyd. crystals of *dl*-rhamnose (I), m. 151.3–3.0°, are obtained by the concn. of an alc. soln. of equal wts. of *l*- (II) and *d*-rhamnose (III). I being anhyd. shows that the mol. of water in II and III is water of crystn. as in the case of glucose monohydrate, and not constitutive water as claimed by Rayman. Reduction of III with Na-Hg gives *d*-rhamnitol, m. 123°, $[\alpha]_D$ —12.4° in water; *dibenzylidene deriv.*, m. 207°, $[\alpha]_D$ 60.7° in $CHCl_3$. IV obtained from II has the same phys. consts. Contrary to Bertrand's rule (*Ann. chim. phys.* [8], **III**, 181–8(1904)), neither II nor α- or β-rhamnohexitol is oxidized by the sorbose bacteria (V) although mannitol is readily attacked, and it is concluded, therefore, that the oxidizing action of V is detd. not only by stereochem. configuration but further by the homologous series to which the alc. belongs. β-Rhamnohexose prepd. according to Fischer and Morrell (*Ber.* **27**, 382) could not be crystd. but gives a cryst. *monobenzylidene deriv.*, m. 233–4°, $[\alpha]_D$ 50.8 in $CHCl_3$. Crystallographic data are given for I. Frederick C. Hahn

Structure of carbohydrates and their optical rotatory power. W. N. Haworth. *Nature* **126**, 238–9(1930); cf. *C. A.* **23**, 1881.—The article is a criticism of two publications on the same subject by Hudson (cf. *C. A.* **24**, 2726–7). The author argues that Hudson is assigning differing structural formulas to explain the anomalies arising from his hypothesis concerning optical rotation and carbohydrate structure at the same time that he is seeking to test that hypothesis. As a test of Hudson's scheme, the author hydrolyzes 4-glucosido-α-methylmannoside and 4-galactosido-α-methylmannoside by means of emulsin, in which case no ring change should occur. The product formed is the ordinary α-Me mannoside ($[\alpha]_D$ 79°) which has a 1,5-ring and not Hud-

son's hypothetical α-Me mannoside ($[\alpha]_D$ 125°). Since this is Hudson's pivotal compd. to which he assigned a 1,4-ring, the author concludes that "the whole of Hudson's rival formulas for mono- and disaccharides become meaningless." A. WIEBEN

Acetonesugars and other compounds of the carbohydrates. XX. Synthesis of methylated cellobiose. Crystalline methylcellotriose from cellulose. Gentiobiose from amygdalin. KARL FREUDENBERG, CARL CHR. ANDERSEN, YUKICHI GO, KARL FRIEDRICH AND NELSON W. RICHTMYER. *Ber.* **63B**, 1961–6(1930); cf. *C. A.* **23**, 2940 (*C. A.* **16**, 3635; **19**, 2034; **22**, 4106, will henceforth be designated as Papers XVII, XVIII, XIX).—In the methylation of cellobiose or β-Me cellobioside, heptamethyl-β-methylcellobioside (I) can be obtained in perfectly homogeneous cryst. form and the efforts to synthesize methylated cellobiose were therefore directed to obtaining this compd. 2,3,6-Trimethyl-β-methylglucoside (II), m. 58–9°, was prepd. in 6 g. yield by converting 12 g. 2,3,6-trimethylglucose with HCl in Et_2O into the 1-chloride and treating the latter with MeOH and Ag_2CO_3. Tetramethylglucose 1-chlorohydrin (III), b_1 100–20°, was obtained in 6–7 g. yield from 6 g. tetramethylglucose with HCl-Et_2O. The condensation of II with III was effected by stirring in $CHCl_3$ with Ag_2CO_3; the monosaccharide derivs. were readily removed by distn. up to 150° under 1 mm.; the higher-boiling fraction (150–205°) yielded 7% of I, m. 86°, $[\alpha]^{18}_{578}$ —16° (±1°) in H_2O. The part remaining after removal of the crystals remained liquid more than 1 yr.; it was *d*-rotatory and can, therefore, have been only a heptamethyl-β-methylmaltoside or a trehalose or isotrehalose deriv. As a matter of fact III alone with Ag_2CO_3 in $CHCl_3$ gives an oily permethylated disaccharide almost free of Cl and with $[\alpha]^{18}_{578}$ 52° (MeOH, 5% soln.). Heptamethylbenzylcellobioside in AcOH with Pt sponge takes up about 4 mols. H_2; the *heptamethylcellobiose*, m. 105 10°, shows mutarotation in 1% H_2O soln., $[\alpha]_{578}$ 53° ⟶ 40°. *Decamethyl-β-methylcellotrioside*, obtained by treating absorbent cotton with Ac_2O-AcOH-H_2SO_4 and repeatedly methylating the alc.-insol. product with Me_2SO_4 (30 g. from 7 100-g. portions of cotton), $b_{0.08}$ 216–20°, m. 115°, $[\alpha]^{20}_{578}$ 9.8° (±0.5°), mol. wt. in camphor 608. Amygdalin in 50% alc. with Pt sponge and H gives gentiobiose, identified as the osazone. **XXI. Some experiments with anhydroglucose.** KARL FREUDENBERG, HANS TOEPFFER AND SYED H. ZAHEER. *Ibid* 1966–9.—It has been found that acetoneglucose 6-bromohydrin (I, R = H) with Ag_2O gives an acetone-anhydroglucose, m. 133° (previously given as 126°) to which was assigned the structure II since Ohle, v. Vargha and Erlbach had given the structure III (R = H) to an isomer, m. 56°, obtained from ditoluenesulfonylacetoneglucose. III has now been obtained by acetonation of Fischer and Zach's 3,6-anhydroglucose (IV) with the aid of H_2SO_4, thus confirming its structure. In the meantime Ohle and v. Vargha have found that II can be readily prepd. from toluenesulfonylacetoneglucose and identified it as an ethylene oxide. II reacts in an unexpected manner with acetobromoglucose, which smoothly adds at the ethylene oxide union to form the same bromodisaccharide V (I, R = $C_6H_7O_5Ac_4$) which had been obtained from I and acetobromoglucose. The corresponding I compd. is obtained from V with NaI or from II with acetoiodoglucose. The remaining HO group in V can be acetylated, but, as before, all efforts to replace the halogen by HO failed; the only definite halogen-free transformation product obtained was an anhydrodisaccharide to which is ascribed the structure VI (III, R = $C_6H_{11}O_5$). III (2 g. from 2.5 g. IV), $[\alpha]^{21}_D$ 31.09° (H_2O); *p*-toluenesulfonate, m. 133°. Acetate of V (10 g. from 8 g. II shaken with Ag_2CO_3 in CCl_4, followed by treatment of the product in C_5H_5N with Ac_2O), m. 169°, $[\alpha]^{18}_D$ —59.75° in $(CHCl_2)_2$. *I analog*, $C_{25}H_{35}O_{15}I$, m. 193°, $[\alpha]^{20}_D$ —76.62° in $(CHCl_2)_2$; 2 g. with $Ba(OH)_2$ in aq. alc. on the H_2O bath gives 0.8 g. *5-glucosidoacetone-anhydroglucose* (VI), m. 130°, $[\alpha]^{20}_D$ 20.16° (H_2O). Acetoiodoglucose, m. 109°, was obtained in 45 g. yield from 50 g. pentaacetylglucose in cold Ac_2O slowly treated with HI (d. 1.7).

XXII. Cyclic acetates in the sugar group. KARL FREUDENBERG AND HELLMUT SCHOLZ. *Ibid* 1969–72.—Haworth, Hirst and Müller attempted to explain the exist-

ence of the remarkable, alkali-stable monoacetate of Fischer, Bergmann and Rabe's Me rhamnoside by assuming a special steric arrangement. B. and S. believe it can be explained on structural chem. grounds by assigning to the compd. the structure (I) of a cyclic acetate. Along with the 2 known heptaacetylchloromaltoses, which presumably have the normal structures, F. and his collaborators had found a 3rd isomer which, in the light of the views prevailing at the time, was assumed to be a "γ-form." When the structure of maltose was later established by Haworth, such a furoid γ-structure was excluded, since the 4-position in maltose is occupied. If, however, the above views as to the rhamnoside are correct and are applicable to maltose also, the 3rd chloromaltose would have the structure II (X = Cl), the heptaacetylmethylmaltoside (III) derived from it the corresponding structure (X = OMe), and the "Me maltoside" (IV) (III with the six AcO groups replaced by HO) obtained from these compds. would still contain an alkali-stable AcO group which at the time had been overlooked. As a matter of fact, the MeO content (7.8%) of the amorphous IV agrees better with that calcd. for the new formula (7.8%) than with the calcd. value (8.7%) for a Me maltoside. The correctness of the new formulas is established by the fact that the well-crystd. III contains an AcO bound differently from the other 6; when it is boiled in alc. with K stearate, only six AcO groups distil over as AcOEt and the 7th is split off only with $MeC_6H_4SO_3H$; the IV, obtained from III with aq. NH_3, likewise splits off an AcO group when boiled in alc. with $MeC_6H_4SO_3H$. II on long contact with C_5H_5N apparently changes into a ketene acetal, —CH(OAc).CH———CH.O—, and $C_5H_5N.HCl$,

O C(:CH_2).O

for the mixt., which at first is not attacked by $KMnO_4$ in Me_2CO, reduces the $KMnO_4$ after it has stood some days at 20°. In view of these results in the maltose series, there can be no doubt as to the correctness of the structure I for the rhamnoside, which has also been established directly by Braun (see following abstr.). In the meantime, Bott, Haworth and Hirst have independently reached the same conclusion (*C. A.* **24**, 4270).

C. A. R.

A new isomerism in the sugar group. EMIL BRAUN. *Ber.* **63B**, 1972–4(1930); cf. preceding abstr. and *C. A.* **24**, 4509.—AcOH and its esters with non-absorbing alcs. have in the ultra-violet a characteristic absorption which is to be ascribed to the C:O group. If "γ-acetylmethylrhamnoside" (I) is a $MeC(OH)_3$ deriv.,

MeCH.CH(OH).CH(OH).CH——CH.O
O.CMe(OMe).O

this characteristic form of the ordinary AcOH absorption should disappear or at least be replaced by a qualitatively different form; its absorption should lie in the region of even shorter wave lengths. Such proved to be the case. The absorption coeff. χ of MeOAc (in hexane) in the region measured is almost 10 times as large as that of I (in alc.), the difference in the logs being 1. This effect cannot well be explained by difference in the solvents or by other phys. influences. For the γ-triacetylmethylrhamnoside, with 2 ordinary AcO groups, the curve for the log χ is about 0.30 unit higher than that for MeOAc, corresponding to 2 mols. MeOAc (log 2 = 0.30). For I and acetoneglucose (II), which, outside of the non-absorbing sugar residue, differ only in that I contains OMe instead of 1 of the Me groups in II, the absorption curves in H_2O almost coincide between 2100 and 1950 A. U., and only in the longer wave lengths do they show a distinct difference. The chem. behavior of I and II is also worthy of note; both are exceedingly non-sensitive to strong alkalies but quite sensitive toward dil. acids. From these results it may be affirmed that I and the triacetate are derivs. of $MeC(OH)_3$. Whether acetobromorhamnose is also a $MeC(OH)_3$ deriv. or whether a rearrangement occurs during the conversion into I with MeOH or quinoline cannot be stated, but at some stage the ordinary Ac group on C atom 2 must react with C atom 1 to form a $MeC(OH)_3$ deriv. C. A. R.

The water-soluble degradation products of lignin. II. HERMANN FRIESE. *Ber.*

63B, 1902–10(1930); cf. *C. A.* 24, 1090.—In a continuation of the earlier work it was found that Ac_2O-AcOH (1:1) contg. 9–10 vol. % H_2SO_4 can convert wood meal in a few days practically quantitatively into completely H_2O-sol. products; if the mixt. is now dild. with 1.5–2 parts $CHCl_3$, the lignin part can readily be shaken out with H_2O without any sugar acetates going over into the H_2O. The product so obtained is a mixt. of substances of different mol. wts., all contg. organically bound S and forming salts, *i. e.*, they are SO_3H acids. It has the av. compn. C 38.7, H 4, S 10–4, and MeO 6–9%, and is also sol. in MeOH, AcOH and Ac_2O; in hot MeOH, however, it is partially esterified. The Ba salt, prepd. with $BaCO_3$, unlike the deep dark brown free acid, is yellowish brown; it is readily sol. in H_2O but can be freed only with difficulty from the last traces of the salt of $HO_3SCH_2CO_2H$, formed from the Ac_2O and H_2SO_4. The Ba salt cannot be fractionated by pptn. from H_2O with alc. The free acid, however, can be sepd. into numerous fractions ranging in compn. from C 55, H 5.85, S 2.55, MeO 13.5%, to C 23.76, H 4.17, S 19.98, MeO 4.5%. The soly. in H_2O decreases with increasing C content and disappears completely when the S content falls to 2%. All the prepns. contg. more than 40% C lose their soly. almost completely on long standing over P_2O_5 or when dried in an oven. Flocculation does not occur, however, even on long standing. When the aq. soln. is filtered through hide powder, 50–60% of the substance is retained. Lignin prepd. by Freudenberg's method behaves in the same way toward the Ac_2O-AcOH-H_2SO_4 mixt., except that about 50% remains undissolved; it nevertheless takes up 5.67% S and the C content falls correspondingly to 48.84%. Only after long treatment with 4 *N* NaOH on the H_2O bath does it completely dissolve. Of the original material, 6% becomes $CHCl_3$-sol., contains 69% AcOH and is optically active (undoubtedly carbohydrate acetates); 40% becomes H_2O-sol., contains C 49.29, H 4.57, S 10, MeO 8.5%, and can be sepd. into 2 parts of the same compn. The free acid cannot be acetylated, and only by treatment of the Ba salt (20.26% Ba) with Ac_2O can 20.76% AcOH be introduced. The anal. results correspond to the formula $C_{12}H_{18/14}O_7S$ or $C_{12}H_8O(OMe)(OH)_2SO_3H$, a dihydroxybenzenesulfonic acid with one HO group etherified with a trihydroxybenzene and the other with MeOH. On the well-founded assumption that true SO_3H acids are formed in this degradation, the parent substance in lignin must be of aromatic, phenolic nature, for sugar and furan complexes do not react in this way. A part of the H_2SO_4 and Ac_2O react to form $AcOSO_3H$ which rearranges into the stable $HO_2CCH_2SO_3H$ which, according to Schneider and his collaborators, reacts with phenol ethers to form Me ketones and pyranhydrones. A no. of phenol derivs. was accordingly treated with the Ac_2O-AcOH-H_2SO_4 mixt., and wood meal and lignin were treated with $HO_2CCH_2SO_3H$. The latter acid in Ac_2O only partially hydrolyzed the polysaccharides in pine-wood meal, without sulfonating the lignin or making it sol. Freudenberg lignin likewise formed no H_2O-sol. product, but 4 g. yielded 0.8 g. of a yellowish $CHCl_3$- and Et_2O-sol. sirup with phenolic odor, contg. C 75.65, H 8.45, MeO 1.73 and no S. This rather surprising result points to a new kind of lignin degradation without sulfonation and the expt. will be repeated on a larger scale. The results of the treatment of phenol derivs. with Ac_2O-AcOH-H_2SO_4 will be dealt with in detail later All multivalent phenols and their ethers are quantitatively converted into the corresponding SO_3H acids. The formation of Me ketones and pyranhydrones was not observed. Phenol derivs. with side chains, like anethole, behave in the same way. Phenolic aldehydes, however, behave differently. Piperonal in a few hrs. gives almost quantitatively a blue-violet, S-free, cryst. condensation product and vanillin yields a dark red substance. The presence of both phenolic and aldehyde groups, therefore, prevents sulfonation, although 1 such group alone does not; PhCH:CHCHO yields a SO_3H acid. These facts seem to establish that lignin is closely related to phenol derivs. C. A. R.

Constitution of lignin. XIII. Separation of aldehydes and ketones by means of β-naphthylamine hydrochloride. PETER KLASON. *Ber.* 63B, 1981–3(1930); cf. *C. A.* 24, 4510.—Expts. with most of the aldehydes which can be bought in the market showed that when treated in H_2O or alc. with β-$C_{10}H_7NH_2$.HCl (I), often along with some HCl, they all condense, whereas ketones (Me_2CO, $C_6H_{11}COMe$, allylacetone, $Me_2CHCOMe$, $(CH_2COMe)_2$, $ClCH_2COMe$, PhCOMe, PhCOEt, *p*-$MeOC_6H_4COMe$) do not react. The lignin reactions with salts of aromatic bases are, therefore, true aldehyde reactions and the formation of the yellow $C_{10}H_7NH_2$ salt of lignosulfonic acid is likewise the result of an aldehyde reaction. With a glucose soln. I has to be boiled several hrs. before any reaction can be observed, and even after a day it is minimal. In 1–0.1 *N* HCl at room temp., no reaction is noted in the course of several days, but on the H_2O bath it takes place in 1–2 days, depending on the strength of the acid, with formation of an insol. substance looking somewhat like peat and having the compn.

of an *anhydro(glucosetri-β-naphthylamine)*, $C_6H_9O_5(NHC_{10}H_7)_3$. It can be methylated or acetylated only to an insignificant extent, is only incompletely broken down by hot concd. HCl and on heating decomps. without melting. *Anhydro(arabinosetri-β-naphthylamine)* and *anhydro(xylosedi-β-naphthylamine)* are obtained in the same way. Heated with a sugar soln. these anhydro(sugartrinaphthylamines) change into anhydro(sugardinaphthylamines). The formation of these compds. seems clearly to be preceded by a hydrolysis of the CH....CH(OH).O group in the sugar to —CH(OH)....-$CH(OH)_2$ which by loss of H_2O forms the aldehyde and this then reacts normally with the I. XIV. *Ibid* 1983–5.—K. had found with Fagerlind that about 2% of the dry wt. of wood can be dissolved out with H_2O alone in the form of 2 compds., one sol. in alc., with the compn. of coniferyl alc. and a mol. wt. of 231 (calcd. 180), and the other sol. in alc., which was thought to be a dimeric hydroxyconiferyl alc. (I). This view has subsequently been materially changed, chiefly as the result of the observation that the compd. gives strong lignin reactions and that the aliphatic part of lignin contains methylated HO groups. The compd. must, therefore, be a dimeric guaiacolpropyleneglycolaldehyde, isomeric with I. K. had also found that a part of the lignin can be dissolved out by boiling with alc. contg. H_2SO_4 or HCl. Holmberg assigned to the substance thus obtained the compn. $C_{40}H_{40}O_{12}$ 2EtOH. According to Freudenberg, lignin contains H_2O in the aliphatic chain and the formation of H.'s compd. might be represented by the equation $C_{40}H_{40}O_{12}.H_2O + 2EtOH = C_{40}H_{42}O_{12}(OEt)_2 + H_2O$. Later, however, K. found that when the sulfite cooking is moderate lignosulfonic acid has the compn. $C_{30}H_{30}O_9.H_2SO_3$. Using $C_{30}H_{30}O_9$ to represent lignin, the formation of the H. compd. could be represented by the equation $C_{30}H_{30}O_9 H_2O + EtOH = C_{30}H_{32}(OH)OEt$. The anal. and mol. wt. results agree better with this formula than with that given by H. It must be assumed, therefore, that in the alcoholysis of wood there are formed hemi-acetals of trimeric coniferaldehyde. Similarly, the anal. values for H.'s lignotetrathioglycolic acid agree well with the calcd. values for $C_{30}H_{32}O_9(SCH_2CO_2H)_2$. It may be stated, therefore, that when native polymeric lignin is so far broken down by acids that free aldehyde complexes are produced the latter can combine with alcs., phenols and mercaptans as well as with H_2SO_3. C. A. R.

The questionable existence of the so-called diamylose. ARTHUR MIEKELEY (WITH E. BEHGE). *Ber.* **63B**, 1957–61(1930).—M. has attempted in vain to convert α-tetraamylose (I) into "α-diamylose" (II) by Pringsheim's method. He always obtained only the acetate of I, irrespective of whether the acetylation was carried out in the presence of $ZnCl_2$ or of C_5H_5N; removal of the Ac regenerated unchanged I with the correct mol. wt. Furthermore, he obtained for pure I and its acetate consts. different from those given by P.; those for the acetate agree, within the limits of exptl. errors, with those of the supposed II. Finally, M. found that I can be obtained in crystals of the compn. $C_{24}H_{40}O_{20}.4H_2O$ or exactly the same as that of P.'s II, $C_{10}H_{20}O_{10}.2H_2O$. The I. $4H_2O$ showed $[\alpha]_D^{22}$ 133.8° (H_2O); anhyd., 147.3°. Its acetate m. 153–4° (cor.), $[\alpha]_D^{18}$ 103.8° (AcOH). *Octabenzoate* of I, obtained in 66% yield with BzCl in C_5H_5N, m. 209° (cor.), mol. wt. in PhOH 1446. C. A. R.

Action of hydrofluoric acid on starch. BURCKHARDT HELFERICH, ARNO STÄRKER AND OTTO PETERS. *Ann.* **482**, 183–8(1930); cf. *C. A.* **24**, 721.—The action of anhyd. HF on dry starch in a Ag crucible at −20° for 0.5 hr. and removal of the HF by a stream of air at room temp. gives 85% crude *amylan*, which, purified through the Ac deriv., analyzes for $(C_6H_{10}O_5)_x$, $[\alpha]_D^{21}$ 144.4°; the reduction of Fehling soln. corresponds to a content of 0.25% glucose; the compd. is easily sol. in H_2O but differs from cellan in that it is insol. in the ordinary org. solvents, including C_5H_5N; heating with Ac_2O in C_5H_5N gives the *tri-Ac deriv.*, $[\alpha]_D^{18}$ 142.5°, sol. in $CHCl_3$, very difficultly sol. in Et_2O. Maltose and HF give *maltan*, $(C_6H_{10}O_5)_x$, $[\alpha]_D^{21}$ 145° (H_2O); *tri-Ac deriv.*, $[\alpha]_D^{17}$ 141.3°. Amylan in HF shows $[\alpha]_D^{14}$ 110°; mercerized cotton shows $[\alpha]_D^{14}$ 1.2°. C. J. WEST

Composition and structure of mesquite gum. ERNEST ANDERSON AND LOUISE OTIS. *J. Am. Chem. Soc.* **52**, 4461–70(1930).—Mesquite gum is the inorg. salt of an org. compd. consisting of 4 mols. of arabinose, 3 mols. of galactose and 1 mol. of methoxyglucuronic acid united with the loss of 7 mols. of H_2O. This pure acid was prepd. by Ehrlich's method and its compn. substantiated by prepn. of 3 degradation products. Hydrolysis of the gum with 3% H_2SO_4 at 80° gives the Ca salt of methoxyglucuronic acid joined to 3 mols. of galactose with the loss of 3 mols. of H_2O; with 2 mols. of galactose with the loss of 2 mols. of H_2O and with 1 mol. of galactose with the loss of 1 mol. of H_2O. The compn. of the first 2 salts was further verified by oxidizing them and

obtaining the Ca salt of methylglucuronic acid joined to 2 mols. of galactose and 1 mol. of galactonic acid with the loss of 3 mols. of H_2O and a salt contg. only 1 mol. of galactose. A tentative structural formula of this complex org. acid is given. C. J. WEST

Composition of Salkowski's araban. C. L. BUTLER AND LEONARD H. CRETCHER. *J. Am. Chem. Soc.* **52**, 4509–11(1930).—The araban of Salkowski is not a simple polymer of arabinose but contains arabinose, galactose, rhamnose and glucuronic acid in about the same proportion as they are present in ash-free gum arabic. Comparative analyses give for araban and arabic acid: pentose (as arabinose) 28.8, 34.3; Me pentose (as rhamnose hydrate) 12.7, 14.2; hexose (galactose) 41.1, 42.1; uronic acid (glucuronic) 19.5, 15.5. C. J. WEST

Extraction of sapropel with various organic solvents. B. K. KLIMOV, V. A. LANIN AND B. I. IVANOV. *Zhur. Prikladnoĭ Khim.* **3**, 631–2(1930).—Mixts. of alc. and C_6H_6 were used. Acids found were: $C_{27}H_{54}O_2$ (m. 80.5°), $C_{28}H_{56}O_2$ (m. 81.5°), $C_{29}H_{58}O_2$ (m. 83.0°), alcs.: $C_{26}H_{74}O$ (m. 83°; acetate m. 68°), $C_{30}H_{62}O$ (m. 68°; acetate m. 54°). This shows close relationship to the bitumen of brown coal. V. K.

Use of nickel as a catalyst for hydrogenation. HOMER ADKINS AND HOWARD I. CRAMER. *J. Am. Chem. Soc.* **52**, 4349–58(1930).—The active Ni catalyst was prepd. by a development of the method of Rather and Reid (*C. A.* **9**, 2653). Et_2O may be used as a solvent up to 197° if the pressure is above 40 atm. and MeOH to 240° if the pressure is above 80 atm. The other common solvents may be used to even higher temps. with similar pressures. Methylcyclohexane is an excellent solvent. Results are reported for 45 representative compds. The HO group of alcs. is in general quite resistant to catalytic reduction but if the HO group is on a C atom to which is attached a benzenoid ring, its replacement by H takes place at 125° or lower. If the HO group was in the β-position with respect to the ring, the rate of its reduction was retarded very greatly. $PhNH_2$ absorbed H more slowly than did the other benzenoid compds. studied. The pyridinoid ring in quinoline is rapidly reduced at temps. from about 125° upward. The benzenoid ring requires a considerably higher temp. for its reduction. The use of Ni permits selective reduction between 2 reducible groups through control of the temp. of hydrogenation; this has been achieved with CH_2AcBz, PhCOEt, benzoin, benzil, Ph_2CO, $PhCH_2CN$, *o*-MeC_6H_4CN and isonitrosopropiophenone when the CO, CN or oxime group is reduced without affecting the benzenoid ring. At 175–200° complete reduction of these compds. occurs. By a similar temp. control it is possible to reduce the pyridinoid ring in quinoline, α- or γ-pyridylphenylethylene and α-benzylpyridine without reducing the benzenoid ring. C. J. WEST

Chemical behavior of some benzenoid hydrocarbons in the Tesla discharge. JAMES B. AUSTIN AND IAN A. BLACK. *J. Am. Chem. Soc.* **52**, 4552–7(1930).—The Tesla discharge in the vapors of C_6H_6 and its simple derivs. causes chem. action with the formation of 2 types of compds.: first, brown shellac-like compds. contg. O which are left in the discharge tube and appear to be condensed mols. of a phenolic type; second, relatively simple mols. which condense in well-defined crystals. In this latter class, Ph_2 is produced from C_6H_6 and $(PhCH_2)_2$ from PhMe; isomers of these compds. are also formed. The low and high refractive indices of $(PhCH_2)_2$ are approx. 1.53 and 1.74. C. J. WEST

Synthesis of propenylbenzene. L. BERT AND M. RAYNAUD. *Compt. rend.* **191**, 454–5(1930); cf. *C. A.* **24**, 2434.—To 4 mols. of finely divided Na suspended in PhMe at 110°, 1 mol. of $PhCH_2CH:CHCl$ was added, drop by drop, and agitated for 1 hr. $PhCH:CHCH_3$ was isolated. No $PhC:CMe$ or $PhCH_2C:CH$ was found among the products. Further studies are to be made to find a clue as to the mechanism of the reaction. I. M. LEVINE

A parallelism between the mobility of hydrogen in the benzene nucleus and the mobility of chlorine in the side chain. S. C. J. OLIVIER. *Rec. trav. chim.* **49**, 996–1001 (1930); cf. *C. A.* **18**, 48; **24**, 4273.—Previous investigations on the velocity of hydrolysis of several benzyl chlorides have shown that the position of a substituent in the benzene nucleus has the same influence on the reactivity of halogen atoms in the side chain as on the H atoms of the nucleus as regards further substitution. These researches were confirmed by Shoesmith and Taylor (*C. A.* **21**, 572) for the substituents F, OMe and azoxy; the present paper deals with the CN and $CONH_2$ groups, with which the same rule was confirmed again. The $CONH_2$ group is *m*-orienting (Taverne, *Rec. trav. chim.* **16**, 253(1897)) and in a mixt. of equal vols. of water and acetone the following pseudomonomol. reaction consts. were found for the hydrolysis of the compds. $C_6H_4(CH_2Cl)CONH_2$: the *m*-compd. at 60°, $K = 0.000203$ and the *p*-compd. $K = 0.000146$; at 50° the *m*-compd. $K = 0.000077$ and the *p*-compd. $K = 0.000055$. The *o*-compd. could not be investigated as it reacts quickly with the formation of a

cyclic compd. For the CN group, Flürscheim and Holmes have found that it is *m*-directing, the nitration of PhCN giving 88% of *m*-$O_2NC_6H_4CN$ (*C. A.* **22**, 4488) and here again it was found that the *m*-deriv. $C_6H_4(CN)CH_2Cl$ is hydrolyzed more quickly than the *o*- and *p*-isomerides, the following figures being obtained: at 60°: for the *m*-compd. K = 0.000062; for the *p*-compd. K = 0.000058, and for the *o*-compd. K = 0.000049; at 50°: for the *m*-compd. K = 0.0000237; for the *p*-compd. K = 0.0000214 and for the *o*-compd. K = 0.0000181. The CN group is more negative than the $CONH_2$ group, the reaction proceeding more slowly with the cyanobenzyl chlorides than with the $CONH_2$ substituted ones, and it appears again that with strongly negative substituents the influence of the position of the group is only small, the same applying also for the nitro group. The prepn. of *m-cyanobenzyl chloride* was already described (*C. A.* **17**, 3489), m. 68–8.5°; that of *p-cyanobenzyl chloride* (*loc. cit.*), m. 80–1°; while *o-cyanobenzyl chloride* was prepd. from *o*-toluidine by analogous methods, m. 59.5–60.5°. *m-Chloromethylbenzamide* was prepd. according to Reinglass (*Ber.* **24**, 2417(1891)), m. 129.5–30°, while the *p-amide* was obtained by sapon. of the nitrile according to Mellinghoff (*Ber.* **22**, 3211(1889)), m. 181–2°. Naphthenic acids, their use and importance. SOMMERFELD. *Rev. gen. Mat. Color* **34**, 55–6(1930). S. K. FORD

The structure of the absorption resonators of organic chromophores. IV. Determination of the number and geometrical arrangement of electrons in a common resonator. DAN RĂDULESCU, V. ALEXA AND F. BĂRBULESCU. *Z. physik. Chem.*, Abt. B., **8**, 365–9(1930); cf. *C. A.* **24**, 89.—The optical properties of crocetin, which is equiv. to a naphthacene mol. opened out into a chain, confirm the structure of the naphthacene common resonator previously proposed. **V. Factors which cause a loss of sharpness of the characteristic absorption bands of a common resonator.** DAN RĂDULESCU AND A. GEORGESCU. *Ibid* 370–81.—Changing substituent groups affects ionization and solvation, and thereby modifies the characteristic absorption bands. The effect of *o*-substitution is greater than that of *p*-substitution. The negative polarity of a Me group exceeds that of a Cl atom. **VI. Chromophore characteristics of the nitro group and the structure of its resonator.** DAN RĂDULESCU AND VASILE ALEXA. *Ibid* 382–94.—The absorption spectra of derivs. of 1,4-dihydroxyphthalazine show that the color of the nitro compds. cannot be attributed to salt formation. Therefore, the NO_2 group can exist in at least 2 electromeric forms. One of these forms, with a negatively polarized N atom, absorbs in the visible range of the spectrum, whereas another form, with a positive N, absorbs in the ultra-violet exclusively. **VII. Polarity of the nitro group in organic derivatives, and the existence of metaquinones.** *Ibid* 395–402.—A combination of the theory outlined in the preceding abstr., and the theory of induced polarity in the C_6H_6 ring gives a satisfactory account of the chem. and optical properties of *s*-$C_6H_3(NO_2)_3$ and its derivs. ALBERT L. HENNE

Pyrolysis of allylanilines. F. L. CARNAHAN AND CHARLES D. HURD. *J. Am. Chem. Soc.* **52**, 4586–95(1930).—$PhNHCH_2CH:CH_2$ (I), b_{23} 115°, b_{745} 218°, heated in a sealed tube at 275° for 12 hrs., gives $PhNH_2$, a gas and a non-volatile tar. When the vapor of I was passed through a pyrex tube at 600° at such a rate that the contact time was 2.5 min., a similar but more deep-seated pyrolysis occurred. I (14 g.) gives nearly 5 g. $PhNH_2$, 2.3 g. of unidentified liquid, 0.5 g. C_6H_6, 2.3 g. tar and 1.3 l. gas (H, olefins, paraffins). At 700° and a contact time of 39 sec., 50 g. I gives 5–7 l. gas, 4.5 g. C_6H_6, 19 g. $PhNH_2$, 1–2 g. quinoline, 7 g. of other liquids and 8 g. of residue. The gas contained 0.7% CO_2, 1.3 g. unsatd. hydrocarbons sol. in 62.5% H_2SO_4, 24% C_3H_6, 18.1% C_2H_4, 4.9 g. O, 15.9% H, 0.6% CO, 34.5% paraffins and N. *Allyl-p-toluenesulfonanilide*, m. 69.3° (cor.). $PhN(CH_2CH:CH_2)_2$, b_{18} 123°, b_{45} 148°, b_{745} 239–40°, n_D^{23} 1.5556; on refluxing 0.146 mol. for 48 hrs., the temp. fell from 240° to 228.5°; 1 l. of gas was evolved; the principal products were 0.104 mol. tar, 0.038 mol. C_4H_6, 0.035 mol. $PhNH_2$ and 0.011 mol. I. A similar resin was obtained by the action of acrolein on $PhNH_2$. *p*-$EtOC_6H_4NH_2$ (*p-toluenesulfonyl deriv.*, m. 110° (cor.)) and $CH_2:CH-CH_2Br$ give *diallyl-p-phenetidine*, b. 164–5°, d_4^{23} 0.9921, n_D^{23} 1.5458. Refluxing 0.138 mol. for 48 hrs. gives 0.080 mol. tar, 0.062 mol. C_3H_4 and 0.091 mol. *p*-$EtOC_6H_4NH_2$. In no case was $CH_2:CHMe$ observed. Mechanisms for the reactions are discussed. C. J. WEST

Degradation of quaternary ammonium salts. II. THOMAS S. STEVENS. *J. Chem. Soc.* **1930**, 2107–19; cf. *C. A.* **23**, 2117.—The generality of the reaction $BzCH_2NMe_2(CH_2Ph)X \xrightarrow{NaOH} BzCH(CH_2Ph)NMe_2$ has been further studied; the replacement of the $PhCH_2$ radical by *m*-$BrC_6H_4CH_2$, *p*-$MeOC_6H_4CH_2$, $PhCH_2CH_2$, benzo-

hydryl or 9-fluorenyl, of the phenacyl group by *p*-bromophenacyl or of the Me_2N system by piperidinium does not prevent the migration. The benzohydryl and fluorenyl radicals wander so readily that the quaternary salts cannot be isolated. The process is shown to be an intramol. one by acting on a mixt. of phenacyl-*m*-bromobenzyldimethylammonium and *p*-bromophenyl bromides with EtONa. Under similar conditions the rates of transformation of the 2 substances separately are of the same order of magnitude and the mixt. yields only the rearrangement products corresponding to the individual salts; further the reaction takes place in alk. solns. (NaOH, KOH, EtONa, NH_3) but not in a neutral medium. Preliminary velocity measurements show that the reaction is unimol. in abs. EtOH-EtONa; the values suggest that the benzyl radicals are detached as anions. *m-Bromobenzyldimethylamine picrate*, orange, m. 139–41°. *Phenacyl-m-bromobenzyldimethylammonium bromide*, from *m*-$BrC_6H_4CH_2NMe_2$ and $BzCH_2Br$, m. 140–3°. *ω-Di-methylamino-ω-m-bromobenzylacetophenone*, m. 72–3°, slowly resinifies on standing; *picrate*, bright yellow, m. 141–3°; the methosulfate rapidly decomps. on boiling, giving *phenyl m-bromostyryl ketone*, m. 84–5°, also formed from *m*-BrC_6H_4CHO and BzMe in MeOH-KOH; H_2SO_4 gives a yellow color, changing to cherry red on addn. of HNO_3. *p*-$MeOC_6H_4CH_2NMe_2$ gives a *picrate*, deep yellow, m. 103–5°. *Phenacyl-p-methoxybenzyldimethylammonium bromide*, m. 133–6°; *picrate*, deep yellow, m. 112–3°. *ω-Dimethylamino-ω-p-methoxybenzylacetophenone*, pale yellow, m. 52–4°; *picrate*, dark yellow, m. 143–5°; the methosulfate with KOH gives $PhCOCH:CHC_6H_4OMe$-*p*. $PhCH_2CH_2NMe_2$ gives a *picrate*, yellow, m. 134–7°. *Phenacyl-α-phenylethyldimethylammonium bromide*, m. 155–7° (decompn.). The crude rearrangement product contained the α- and β-isomers approx. in the ratio 4:5, the picrates were sepd. by recrystg. the product from dil. AcOH, which yields preferentially the α-form, or from Me_2CO-light petroleum from which the β-form sepd. most readily. *ω-Dimethylamino-ω-α-phenylethylacetophenone*, α-form, m. 111–2° (*picrate*, yellow, m. 186–7°); *β-base*, bright yellow, m. 111–3° (*picrate*, pale yellow prisms or deep yellow nodules, m. 174–6°); the α-form is unchanged by heating at 100°, while the β-form was completely changed into the α-form. *ω-Bromo-ω-α-phenylethylacetophenone*, m. 76°, with Me_2NH in EtOH gives the above β-form. *Benzohydryldimethylamine*, m. 68–9°; *picrate*, yellow, m. 196–8°; *HBr salt*, m. 215°, crystals with 1 mol. H_2O. $BzCH_2Br$ gives *ω-dimethylamino-ω-benzohydrylacetophenone*, pale yellow, m. 167° (decompn.); the methosulfate, with alkali, gives ω-benzohydrylideneacetophenone. 9-Fluorenyldimethylamine gives a *HBr salt*, m. 204–6°; *ω-dimethylamino-ω-fluorenylacetophenone*, pale yellow, m. 145–8° (decompn.); if the prepn. is carried out in hot C_6H_6, the main product is *fluorenylideneacetophenone*, deep yellow, m. 137–40°, also obtained from the *Br deriv.*, m. 111–3°, decomps. 160°, of fluorenylacetophenone and aq. Me_2NH. *p-Bromophenacylbenzyldimethylammonium bromide*, m. 188–91°. *p-Bromo-ω-dimethylamino-ω-benzylacetophenone*, pale yellow, m. 106–7°; *HCl salt*, m. 235–8° (decompn.); decompn. of the methosulfate gives *p*-BrC_6H_4CO-$CH:CHPh$. *Phenacylbenzylpiperidinium bromide*, m. 135–8° (decompn.), crystals with 1 mol. H_2O. *ω-Piperidine-ω-benzylacetophenone*, m. 80–1°; *picrate*, deep yellow, m. 185–7° (decompn.). III. Thomas S. Stevens, Wm. W. Snedden, Eric T. Stiller and Thomas Thomson. *Ibid* 2119–25.—Replacement of the Ph group by Ac does not prevent the above rearrangement. $ClCH_2Ac$ and $PhCH_2NMe_2$ in C_6H_6 give *acetonylbenzyldimethylammonium chloride*, m. 75–7°, crystals with 1 mol. H_2O; *picrate*, dark yellow, m. 141–3°; heating the chloride with *N* NaOH gives *α-dimethylamino-α-benzylacetone*, whose picrate, yellow, m. 140–4°. *Carbethoxymethylbenzyldimethylammonium chloride*, m. 176° (decompn.), hygroscopic; *picrate*, yellow, m. 126–8°; no rearrangement occurs by heating the chloride with NaOH or EtONa, the ester being hydrolyzed to the free *acid*, whose *picrate*, bright yellow, m. 146–8°. $ClCH_2CN$ and $PhCH_2NMe_2$ in cold Et_2O give a viscous gum, from which was prepd. *cyanomethylbenzyldimethylammonium picrate*, bright yellow, m. 140–3°; this does not rearrange with NaOH, but the CN group is hydrolyzed to CO_2H. *p-Bromobenzyldimethylamine-HCl*, m. 219–20°; *di-p-bromobenzyldimethylammonium picrate*, deep yellow, m. 165–7°. *Phenacyl-p-bromobenzyldimethylammonium bromide*, m. 193°; heating with excess 2 *N* NaOH gives *ω-dimethylamino-ω-p-bromobenzylacetophenone*, m. 61°; *picrate*, dark yellow, m. 149–50°. *Phenacyl-p-nitrobenzyldimethylammonium bromide*, m. 169–71°; heating on the H_2O bath for 7 min. with excess *N* NaOH gives some $(p\text{-}O_2NC_6H_4CH_2)_2$ and *p*-$O_2NC_6H_4Me$ and about 60% of *ω-dimethylamino-ω-p-nitrobenzylacetophenone*, light yellow, m. 79–82° (picrate, yellow, m. 144–5°); stronger alkali or prolonged heating gives *p*-$O_2NC_6H_4CH:CHBz$. *Phenacylbenzylmethylamine*, b_{15} 195–205°; *picrate*, yellow, m. 137–8°. *Benzyl-p-bromobenzylmethylamine*, b_{20} 194–6°. The salt $BzCH_2N(CH_2C_6H_4Br)MeXCH_2Ph$ could not be obtained. C. J. West

Reaction mechanism of formazyl formation. II. M. BUSCH AND RICHARD SCHMIDT. *Ber.* **63B** 1950–2(1930), cf. *C. A.* **20**, 2992.—v. Pechmann observed that aldohydrazones of secondary hydrazines yield no formazyl compds. with diazonium salts but was unable to offer any explanation of this anomalous behavior. Busch and Pfeiffer later showed that in the formazyl syntheses the diazonium compd. first adds to the NH group of the hydrazone and the resulting diazohydrazide rearranges into the stable formazyl: $RNHN{:}CHR' + R''N_2OH \longrightarrow RN(N{:}NR'')N{:}CHR' \longrightarrow RNHN{:}C(N{:}NR'')R'$. They afterward found that Bamberger had reported (*Ber.* **29**, 1387(1896)) that free *p*-nitroisodiazobenzene hydroxide combines with PhMeNN:CHPh to the formazyl $PhMeNN{:}C(N{:}NC_6H_4NO_2)Ph$. As this is directly contrary to the above conception of the mechanism of the formazyl synthesis, Bamberger's work has been repeated and his exptl. results have been confirmed, but his interpretation was incorrect. The product is in reality an azo compd., $O_2NC_6H_4N{:}NC_6H_4NMeN{:}CHPh$ formed by coupling on the Ph nucleus of the $PhMeNNH_2$. This is shown by the following facts: (1) I is hydrolyzed by dil. H_2SO_4 to BzH; (2) on reduction it gives *p*-$C_6H_4(NH_2)_2$ and a primary aromatic amine. $H_2NC_6H_4NMeN{:}CHPh$. Furthermore, the hydrazone of $Ph(PhCH_2)NNH_2$ behaves in the same way, giving a *compd.* $O_2NC_6H_4N{:}NC_6H_4N(CH_2Ph)N{:}CHPh$ (I), while that of $(PhCH_2)_2NNH_2$ gives not a trace of azo compd., probably because $(PhCH_2)_2NN{:}CHPh$ contains no nucleus capable of coupling. I, obtained in 5% yield, red, m. 199–200°. C. A. R.

Constitution and reactions of the isomeric diazo hydrates. ANGELO ANGELI. *Ber.* **63B**, 1977–80 (1930); cf. *C. A.* **24**, 81.—Reply to Hantzsch (*C. A.* **24**, 4001). C. A. R.

Organo-antimony compounds. IV. Stibonic acids derived from certain local anesthetics. SUDHIR C. NIYOGY. *J. Indian Chem. Soc.* **7**, 577–87(1930).—An attempt to prep. the 6 possible isomeric nitro and amino derivs. of $PhCH_2OBz$ with a view to obtaining the corresponding stibonic acid for use in the treatment of kala-azar. *Benzyl 2-nitrobenzoate* was prepd. by the addn. of $PhCH_2OH$ in pyridine to *o*-$O_2NC_6H_4COCl$ made by the action of $SOCl_2$. It is reduced by Al-Hg in moist ether to *benzyl 2-aminobenzoate-HCl* (I) m. 162–3° *3-Amino isomer* (II), m. 199–200°, was obtained by satg. the alc. NH_3 soln. of the nitro compd. with H_2S, evapg. to dryness, and refluxing with Cu powder. *4-Amino salt* (III), m. 90–1°, was similarly produced. *2-Nitrobenzyl benzoate*, m. 101–2°, was prepd. by condensing BzCl in pyridine with 2-$O_2NC_6H_4CH_2OH$ obtained by the action of KOH on the aldehyde. Moist ether and Al-Hg reduced it to *2-aminobenzyl benzoate* (IV), m. 144–5°. 3-$O_2NC_6H_4CH_2OH$, converted by PCl_5 to the chloride, when condensed with BzONa, gave *3-nitrobenzyl benzoate*, m. 71–2°, which on reduction yielded *3-aminobenzyl benzoate-HCl* (V), m. 198–9°. *4-Nitrobenzyl benzoate*, m. 94–5°, was similarly prepd., but the reduction was unsuccessful. I, II and III were converted into the corresponding sodium stibonates by diazotizing in HCl, and adding $SbCl_3$. The yellow addn. product was suspended in water, cooled to 5°, and made alk. with 5% NaOH. The stibonic acid was pptd. with H_2SO_4, and after washing was neutralized with NaOH. C. R. ADDINALL

Aromatic arsenic compounds containing sulfur groups attached to the nucleus. I. Sulfonic acids and their derivatives. HARRY J. BARBER. *J. Chem. Soc.* **1930**, 2047–53.—A systematic investigation is proposed of the applicability to As compds. of the methods available for the introduction and transformation of S groups; the possibility that the trypanocidal activity of As compds. is in some way connected with the SH group present in animal tissue makes the prepn. of such compds. containing S groups and SH groups in particular of considerable interest. 3-$NH_2C_6H_4AsO_3H_2$, diazotized and treated with K Et xanthate, gives a poor yield of *3-sulfophenylarsonic acid*, prisms, very sol. in H_2O; it is unlikely that it can be prepd. by Bechamp's method (Krishna and Krishna, *C. A.* **24**, 1096). It seems probable that direct sulfonation only occurs with the simple $HOC_6H_4AsO_3H_2$. The 4-HO deriv. (30 g.), heated for 1.5–2 hrs. at 100° with concd. H_2SO_4, gives 15 g. of the *3-sulfo deriv.*, giving a wine-red color with $FeCl_3$; the 2,4-$(HO)_2$ deriv. gives the *5-sulfo deriv.*, giving a red color with $FeCl_3$. The 4-NH_2, 4-AcNH, 3,4-HO(AcNH) and 4-Cl derivs. failed to give sulfonation products, even under most drastic conditions. The use of $ClSO_3H$ has no advantage over H_2SO_4. The Bart reaction appears not to be applicable to $H_2NC_6H_4SO_2H$; however, *p*-$H_2NC_6H_4SO_2Me$ gives 36% of *4-methylsulfonylphenylarsonic acid*. 2-$IC_6H_4AsO_3Na_2$ (350 g.), 140 g. Na_2SO_3 and a trace of $Cu(OAc)_2$, concd. until the soln. had a b. p. of 106–10° and then boiled for 1 hr., give 90–5% of the *Ba salt*, plates, of *2-sulfophenylarsonic acid*, prisms. *2-Iodo-5-aminophenylarsonic acid*, prisms results in 65% yield by reducing the NO_2 deriv. with $Fe(OH)_2$; *Ac deriv.*, prisms crystg. with 1 mol. H_2O; Na_2SO_3 gives the *2-sulfo deriv.*, fibrous needles; the Ac deriv. was not obtained pure. 2-Br- and

4-$IC_6H_4AsO_3H_2$ do not react under these conditions. 2-$HO_3SC_6H_4AsO_3H_2$ is not changed by boiling with 25% H_2SO_4 or NaOH; the Na salt (20 g.) with 10 cc. PCl_3 and 40 g. PCl_5 gives probably *2-chlorosulfonylphenylchlorohydroxyarsine*, which did not solidify and is slowly hydrolyzed by cold H_2O to *2-chlorosulfonylphenylarsenious oxide* (I) (70–5% yield), oxidized by H_2O_2 to the *arsonic acid;* with NH_4OH and H_2O_2 the oxide gives *2-sulfonamidophenylarsonic acid*, square plates; *thiolacetamide deriv.*, m. 171–3°; the *2-sulfonanilino deriv.* of the oxide is amorphous; $HSCH_2CONH_2$ gives *di(carbaminomethyl)-2-sulfonanilinophenylthioarsonite.* The oxide and excess HI and a little Et_2O give *2-sulfonanilinophenyldiiodoarsine*, yellow prisms. *2-Sulfonanilinophenylarsonic acid*, square plates, results by oxidation of the oxide or the action of $PhNH_2$ on the Cl deriv. I and Na_2SO_3 in H_2O give 80% of *2-sulfinophenylarsenious oxide*, prisms; on titration in $NaHCO_3$ it absorbs 2 atoms I; *Ag salt*, amorphous; MeI in MeOH, followed by oxidation, gives *2-methylsulfonylphenylarsonic acid*, prisms. C. J. WEST

Boron-carbon linkage. I. Oxidation and nitration of phenylboric acid. ARTHUR D. AINLEY AND FREDERICK CHALLENGER. *J. Chem. Soc.* 1930, 2171–80.—The existence in phenylboric acid (I) of an incomplete octet with only 6 electrons, Ph:B:OH, with ·· OH renders a discussion of its structure and reactions of particular interest. The formula is not Ph:B⋮O nor Ph:B ⟶ O, since a compd. of this formula is obtained on dehydrating I. I reacts readily at the ordinary temp. with Cl- or Br-H_2O, with I in KOH and with H_2O_2, giving benzene halides and PhOH, the halogens appearing to react in the form HOX. I readily gives C_6H_6 when heated with 50% NaOH, with H_2O under pressure or boiling concd. HCl. I and hot satd. HgBr give PhHgBr. $CuCl_2$ and I, boiled some hrs., give 85% of PhCl; $CuBr_2$ gives PhBr; $Cu(CN)_2$ gives PhCN (7%), the other product probably being C_6H_6. I and $CdBr_2$, boiled 6.5 hrs., give C_6H_6 (78%); $ZnCl_2$ gives 84% C_6H_6. Nitration of I in H_2SO_4 below —7° gives *m-nitrophenylboric acid* (II), m. 273° (decompn.); with $CuCl_2$ II gives *m*-$ClC_6H_4NO_2$; $HgCl_2$ gives *m*-$O_2NC_6H_4HgCl$; Br in H_2O gives *m*-$BrC_6H_4NO_2$; H_2O_2 gives *m*-$O_2NC_6H_4OH$. The yield of II is about 70%; the presence of *o*- and *m*-NO_2 isomers was shown by the formation of some 2,4-$(O_2N)_2C_6H_3Br$ on nitration of the mixt. of $BrC_6H_4NO_2$ obtained from the crude nitration product. Hot aq. solns. of $BeCl_2$, $MgCl_2$ and $CaCl_2$ do not react with I. I does not react with hydroferrichloric acid and, therefore, is probably almost devoid of basic properties. C. J. WEST

Forced reaction between anils and *p*-thiocresol. Reducing action of the mercapto group. HENRY GILMAN AND J. B. DICKEY. *J. Am. Chem. Soc.* **52**, 4573–6(1930).—In continuation of studies on the unique 1,4-addn to a conjugated system which is part aliphatic and part aromatic, $Ph_2C:NPh$ and PhCH:NPh were heated with *p*-MeC_6H_4SH. No 1,4-addn. was observed. Instead the MeC_6H_4SH acted as a reducing agent and was converted to $(p\text{-}MeC_6H_4S)_2$. It also reduces PhN:NPh but not $PhNO_2$ or Ph_2CO. *p*-MeC_6H_4SMgI does not react with the anils. C. J. WEST

Dinitration of monosulfonated *m*-chlorophenol and the sulfonation and subsequent further nitration of 3-chloro-2- and -6-nitrophenols. HERBERT H. HODGSON AND ARNOLD KERSHAW. *J. Chem. Soc.* **1930**, 2169–71.—*m*-ClC_6H_4OH (12.8 g.) in 10 cc. concd. H_2SO_4, treated with 32 g. oleum (25% SO_3) below 15° and after 1 hr. with 8.8 cc. HNO_3 in 30 cc. oleum below 20° gives, after hydrolysis in a current of stream, 4.6 g. of the 2,6-$(NO_2)_2$ deriv. and 10.2 g. of the NH_4 salt of the 2,4-deriv.; sulfonation at 100°, followed by nitration and hydrolysis as above, gives 14 and 2.4 g., resp., of the 2,4- and 2,6-$(NO_2)_2$ derivs. 3,2-$Cl(O_2N)C_6H_3OH$ with oleum (30% SO_3) at 20° gives *K 3-chloro-2-nitrophenol-4-sulfonate*, light yellow needles, crystg. with 2 mols. H_2O; nitration of the reaction mixt. gives a mixt. of the *K salts* of *3-chloro-2,6-dinitrophenol-4-sulfonate* and *3-chloro-2,4-dinitrophenol-6-sulfonate*, yellow plates and deeper yellow needles; hydrolysis gives 4.1 and 2.7 g. of the 3,2,6- and 3,2,4-$Cl(O_2N)_2C_6H_2OH$. 3,6-$Cl(O_2N)C_6H_3OH$ and oleum give the *4-sulfonic acid deriv.*, whose *K salt*, pale fawn prisms, crystallizes with 2 mols. H_2O. Nitration gives 3,2,6-$Cl(O_2N)_2C_6H_2OH$. *K 3-chloro-2,6-dinitrophenyl-4-sulfonate*, yellow plates; it decomps. with great violence on being heated. 3,4-$Cl(O_2N)C_6H_3OH$ is completely destroyed during attempted sulfonation. C. J. WEST

Action of aromatic alcohols on aromatic compounds in the presence of aluminum chloride. V. Benzylation of *o*-cresol. R. C. HUSTON, H. A. SWARTOUT AND GLADYS K. WARDWELL. *J. Am. Chem. Soc.* **52**, 4484–9(1930); cf. *C. A.* **21**, 1982.—*o*-MeC_6H_4OH and $PhCH_2OH$ with $AlCl_3$ give as the main product the 4-benzyl deriv., b_5 167–9°, m. 49.5–50.5° (*6-Br deriv.*, b_5 182–4°; Bz deriv., m. 54–5°); a 2nd product is the 6-benzyl deriv., b_5 150–2°, m. 49.5–50.5° (*4-Br deriv.*, b_5 187–9°, m. 63–4°; Bz deriv.,

b_5 216–8°); a 3rd product was the 4,6-dibenzyl deriv., b_5 225–7°. *o*-MeC_6H_4ONa and $PhCH_2Cl$ in PhMe give an excellent yield of the 6-benzyl deriv. C. J. WEST

Action of monochlorodimethyl ether on magnesium benzyl chloride. ARTHUR C. BOTTOMLEY, ARTHUR LAPWORTH AND ARTHUR WALTON. *J. Chem. Soc.* 1930, 2215–6.—D. R. P. 154,658 (1904) states that $PhCH_2MgCl$ and $ClCH_2COMe$ give $MeC_6H_4CH_2OMe$. Reëxamn. of the reaction shows that a little *o*-$MeC_6H_4CH_2OMe$ is formed but that it is accompanied by *p*-$MeC_6H_4CH_2OMe$ and a very much larger quantity of $PhCH_2CH_2OMe$, as well as other products of higher b. p. C. J. WEST

Chlorimines. III. Decomposition of certain aromatic ald-chlorimines to form nitriles. Method for the preparation of nitriles from aldehydes. C. R. HAUSER AND A. G. GILLASPIE. *J. Am. Chem. Soc.* 52, 4517–9(1930); cf. *C. A.* 24, 5739.—Aromatic ald-chlorimines react with EtONa or KOH in EtOH to give nitriles; the following yields were obtained (yields for the first 3 are reported for both reagents and are practically the same): anisal, 94; *o*-chlorobenzal, 85; piperonal, 96; 2-chloro-5-nitrobenzal, 82; *p*-chlorobenzal, 60; *m*-nitrobenzal, 82; *o*-nitrobenzal, 70. *o*-Chlorobenzalchlorimine at 0° is completely decompd. within 1.5 mins., while anisalchlorimine is only 45% decompd. after 2 min. and is completely decompd. after 5 min. This represents a method for the prepn. of nitriles from aldehydes, since the latter are readily converted into ald-chlorimines. C. J. WEST

Production of benzaldehyde from benzyl chloride. P. SHORUIGIN, I. KIZBER AND E. SMOL'YANINOVA. *Zhur. Prikladnoĭ Khim.* 3, 721–6(1930); cf. *C. A.* 23, 4186.—Boiling of $PhCH_2Cl$ with aq. $Ca(NO_3)_2$ yields 60–5% BzH and 10% BzOH. The reaction consists of 3 phases: sapon. of $PhCH_2Cl$ with water, displacement of HNO_3 from $Ca(NO_3)_2$ by the HCl formed, and oxidation of the $PhCH_2OH$ produced by HNO_3. The presence of Al or Cu hinders the last reaction. Free HNO_3 can be substituted for its salts. $PhCH_2ONO_2$ is a by-product which on heating with water yields BzH and BzOH. In the absence of water it does not decomp. below 140°. V. K.

Catalytic production of acetophenone. I. G. LAKOMKIN. *Zhur. Prikladnoĭ Khim.* 3, 555–72(1930).—PhCOMe was obtained by interaction of AcOH and BzOH in presence of ThO_2 or MnO catalysts. The amt. of catalyst used affects the yield only if the acid vapors are not preheated. The yield increases with the increase in the reaction temp. up to 600° but then falls off sharply. This increase in yield is less marked if the vapors are preheated. Expts. show that preheating of the reacting vapors is highly important for most economical operation on a com. scale. MnO is a better catalyst than ThO_2. V. KALICHEVSKY

Chlorine derivatives of vanillin and some of their reactions. L. CHAS. RAIFORD AND J. G. LIGHTY. *J. Am. Chem. Soc.* 52, 4576–86(1930).—2-Aminovanillin through the diazo reaction gives 88% of the *2-Cl deriv.* (I), m. 128–9°; *oxime*, m. 157–8°; *p-bromophenylhydrazone*, brown, m. 144–6°; *semicarbazone*, crystals with 1 mol. EtOH, m. 220–1°; *bisbenzidine*, orange, m. 224–6°. Direct chlorination of vanillin gives 92% of the 5-Cl deriv. (II), m. 163°; excess Cl gives some 2,5- and 2,6-di-Cl derivs. II was characterized by the *oxime*, m. 172°; *p-bromophenylhydrazone*, yellow, m. 161°; *semicarbazone*, m. 201°; *bisbenzidine*, yellow, m. 252–4°. II, Ac_2O and AcONa, boiled 3 hrs., give the *Ac deriv.*, light yellow, m. 201°, of *3-methoxy-4-hydroxy-5-chlorocinnamic acid*, m. 235–6°. 3,4-$MeO(OAc)C_6H_3CH(OAc)_2$ with Cl gives 91% of the *6-Cl deriv.* (III), m. 143–4°, hydrolyzed by KOH to *6-chlorovanillin* (IV), m. 167–8°; *oxime*, m. 178°; *p-bromophenylhydrazone*, pale brown, m. 174°; *semicarbazone*, m. 241°; *bisbenzidine*, yellow, amorphous, decomps. 263°; Br in AcOH and AcONa gives the *5-Br deriv.*, m. 214°. 6-Bromovanillin and Cl in $CHCl_3$ give the *5-Cl deriv.*, m. 202°. Nitration of III gives 61% of *acetyl-2-nitro-6-chlorovanillin*, m. 81–2°, becomes lemon-yellow in the light; hydrolysis gives *2-nitro-6-chlorovanillin*, m. 155–7°; reduction with $FeSO_4$ gives 92% of the *2-NH_2 deriv.*, yellow, m. 192–3°, which yields, through the diazo reaction, 40% of *2,6-dichlorovanillin* (V), m. 139–40°; *oxime*, m. 141°; *semicarbazone*, m. 213°; *bisbenzidine*, red, amorphous, m. 232°. II and Ac_2O in AcOH give nearly quant. the *Ac deriv.*, b_5 167–72°, m. 67°; HNO_3 gives nearly quant. the *2-NO_2 deriv.*, crystg. with 1 mol. EtOH, m. 95–6°; KOH gives *2-nitro-5-chlorovanillin*, pale yellow, m. 137°; *2-NH_2 deriv.*, light brown, m. 136–7°; *2,5-dichlorovanillin*, m. 179° (83% yield); this also results on further chlorination of I; *oxime*, m. 158°; *p-bromophenylhydrazone*, m. 158°; *semicarbazone*, crystg. with 1 mol. H_2O, m. 228°; *bisbenzidine*, yellow, m. 254–5°. Refluxing II with Ac_2O contg. a little concd. H_2SO_4 gives 97% of *3-methoxy-4-acetoxy-5-chlorobenzal diacetate*, m. 115–6°; excess of Cl in AcOH and AcONa gives the *5,6-di-Cl deriv.*, m. 117–8°; hydrolysis gives *5,6-dichlorovanillin*, m. 192°; *oxime*, m. 203° (decompn.); *p-bromophenylhydrazone*, yellow, m. 163–4°; *semicarbazone*, m. 237°; *bisbenzidine*, yellow, decomps. at 289°. V and SO_2Cl_2 in $CHCl_3$

give 31% of *2,5,6-trichlorovanillin*, m. 154°; *oxime*, m. 173°; *semicarbazone*, m. 219°. V and Br in AcOH give 96% of the *5-Br deriv.*, m. 167°. In no case was there obtained more than 1 of the stereoisomeric oximes demanded by theory; the one obtained, probably the *anti*-form, could not be transmuted by HCl. C. J. West

Quantitative investigation of the Schotten-Baumann reaction. F. A. Menalda. *Rec. trav. chim.* **49**, 967–95(1930).—When an acid chloride is allowed to react with an alk. mixt. of water and alc., part of it is converted into the ester, alk. hydrolysis taking place at the same time with the formation of the salt of the corresponding acid. In the latter reaction 2 equivs. of alkali are consumed against only one in the former and thus the amount of ester formed may be derived easily from the amount of alkali used in both the simultaneous reactions. In order to investigate this reaction more closely, the following procedure was adopted. A thin-walled glass tube was filled with a small amount of the acid chloride, sealed hermetically and brought into the desired reaction mixt., contg. a slight excess of alkali and cooled down to the desired temp. After having broken the glass tube with a glass rod the mixt. was shaken vigorously for several min. until the acid chloride had disappeared and then 25 cc. were titrated after several intervals of time. As time goes on, the amount of alkali diminishes by the hydrolysis of the ester initially formed and the total amount of ester hydrolyzed was detd. by extrapolation from the figures obtained in 3 consecutive titrations. *A. The effect of temp. on the quantity of ester formed in the reaction.*—With BzCl, NaOH and 10% EtOH, 60.6% ester was obtained at 0°, 60.4% at 2.5°, 57.0% at 10°, 52.2% at 17.5°, 44.0% at 25°, 40.3% at 32.5°, and 26.1% at 47.5°. With 20% EtOH, 65% of ester was obtained at 25°, and 81.8% at 0°; with 30% EtOH, 76% at 25°, and 86.8% at 0°, with 50% EtOH, 83% at 25° and 93.8% at 0°; with 70% EtOH, 87% at 25° and 95.3% at 0°. The following results show that alterations in temp. have the same effect in MeOH as in EtOH: with 2% MeOH, 59% ester was obtained at 25° and 76.6% at 0°; with 5% MeOH, 77% at 25° and 90.4% at 0°; with 10% MeOH, 86% at 25° and 93.4% at 0°, with 20% MeOH, 93% at 25° and 94% at 0°. Again the same result was obtained with AcCl and MeOH and thus it may be concluded *that in the Schotten-Baumann reaction the yield of ester is greater the lower the temp.* This result is in agreement with the observations of previous investigators (cf. Houben-Weyl, *Methoden der org. Chemie* II, 501(1922) (cf. *C. A.* **17**, 1968); Brühl, *Ber.* **36**, 4272(1903)) and confirms the work of Caudri (*C. A.* **23**, 4647) on the reaction of Ac_2O on aq. alcs. *B. The effect of the nature of the acid chloride used on the quantity of ester formed in the reaction* — With $PhSO_2Cl$, NaOH and EtOH the following results were obtained at 0°: with 10% EtOH, 28% ester, with 20% EtOH, 45.6%; with 30% EtOH, 64.5%; with 50% EtOH, 81.2%; with 70% EtOH, 88.3%. With AcCl consistent results could not be obtained at 0° and therefore expts. with this acid chloride were carried out at 25°: with 10% EtOH, 4.8% ester was obtained; with 20% EtOH, 8.0%; with 30% EtOH, 22.7%; with 50% EtOH, 34.8%; with 70% EtOH, 52.1%. These figures show that the amount of ester formed under various exptl. conditions increases in the order: AcCl, $PhSO_2Cl$, BzCl and it could be shown that the same order holds with sucrose and MeOH. At 0°, BzCl gives 88.4%, 93.0% and 96.8% ester with 1%, 2% and 5% sucrose solns. while $PhSO_2Cl$ gives 76.6%, 82.3% and 96.4% ester under the same conditions. With AcCl at 25°, 2.5% MeOH gave 1.3% ester; 5% MeOH, 5.1%; 10% MeOH, 8.6%; 20% MeOH, 17.3%; 50% MeOH, 41.3%; 80% MeOH, 69.2%. From these results the following rule was deduced: *When an acid chloride reacts with an alc. A to give more ester than a second chloride, it will give more ester than the second chloride with an alc. B. C. The effect of concn. and the nature of the alc. on the quantity of ester formed.*—In addn. to the expts. already described, the following results were obtained with BzCl: 1% $PhCH_2OH$, 45.7% ester; 2% $PhCH_2OH$, 63.4% ester; 1% allyl alc., 37.6 ester; 2% allyl alc., 45.3% ester; 10% allyl alc., 72.8% ester; 1, 2 and 5% glycerol, 76.3, 86.6 and 91.2% ester; 1, 2 and 5% sucrose, 88.4, 93.0 and 96.8% ester; 0.5% phenol, 98% ester. It is at once obvious that different kinds of alcs. give very different yields of ester under the same exptl. conditions; on converting the alc. % into mol. OH %, the amount of ester formed increases in the order: EtOH, allyl alc., MeOH, $PhCH_2OH$, glycerol, sucrose, phenol. The polyhydric alcs. investigated so far are benzoylated easily whereas phenol is converted almost quantitatively into the Bz ester. In all the cases investigated the amount of ester increases with increasing concn. of the alc. The following conclusion is drawn: *When an alc. gives more ester with an acid chloride A than another alc., the same applies with another acid chloride B. D. The effect of concn. and the nature of the alkali on the quantity of ester formed.*—Small alterations in the concn. of alkali have but a small effect on the yield of ester but in general the amount of ester decreases with increasing excess of alkali used, although

the influence of this factor is not considerable. Both at 0° and at 25°, KOH gives a somewhat larger yield of ester than NaOH, the difference being small. In this connection attention is drawn to the expts. of Tasman (*C. A.* **22**, 240, 584) and Caudri (*C. A.* **23**, 3393) on the hydrolysis of phthalide with different alkalies, Tasman finding K = 12.1 at 25° with KOH and Caudri 14.07 with NaOH. From the foregoing results it follows that the following conditions are to be maintained in the prepn. of esters by means of the Baumann-Schotten reaction in order to obtain high yields of ester: (1) the temp. must be as low as possible; (2) the acid chloride must be added in portions to prevent the sudden evolution of heat; (3) KOH should be used in preference to NaOH, although the latter gives excellent results; (4) the alkali must be as concd. as possible; (5) in order to prevent hydrolysis the ester is to be removed from the reaction mixt. as quickly as possible; (6) an excess of acid chloride is to be used to obtain a reasonable yield of ester, as a rule 1.2–1.5 times the calcd. amount being necessary. In order to obtain better yields, acetone is sometimes used as a solvent in the reaction, but at 25° the following amounts of ester were formed from acetone: with 25% acetone, 8% ester; with 50% acetone, 18% ester, with 65% acetone, 25% ester; with 80% acetone, 36% ester. In mixts. of acetone and alkali an equil. is established between acetone and diacetone alc. (Koelichen, *Z. physik. Chemie* **33**, 129(1900)), but as the same results were obtained with acetone-alkali mixts. which were kept in the ice chest for 2 days in order to obtain the equil. mixt. with diacetone alc. and with the same mixts. freshly prepd., the conclusion is drawn that the reaction is not due to the diacetone alc., but to the acetone itself, which has reacted in the enolic form. The Schotten-Baumann reaction may be used also for the detn. of the strength of alc.-water mixts. and for the quant. estimation of phenols, as was shown experimentally for phenol and resorcinol. A more complicated application of the reaction to quant. analysis would be the detn. of MeOH in mixts. of MeOH and EtOH after having constructed a graph for such mixts. of known compn.

C. F. VAN DUIN

Keto-enol equilibrium of ethyl α-phenylacetoacetate. HOWARD W. POST AND GLADYS A. MICHALEK. *J. Am. Chem. Soc.* **52**, 4358–62(1930).—A method is given for the prepn. of $AcCHPhCO_2Et$, which is a modification of that of Beckh (*Ber.* **31**, 3160 (1898)). Reliable data from Br titration of this ester show that it has an enol content at equil., room temp., in pyrex glass, of 28.6%. A mechanism is suggested for this series of reactions. Data on the enol content, obtained from a detn. of the mol. refraction, show 137.13%, obviously unreliable. $AcCHPhCO_2Et$ b_{11} 145–7°, d_4^{20} 1.0850, n_D^{20} 1.5130. The increase in enol content of the α-Ph ester over that of the unsubstituted ester is ascribed to the greater electronegativity of the Ph over H and the abnormally large value obtained by the refractive index, to the presence of the anomalous C_6H_6 ring.

C. J. WEST

Reaction between quinone and cinnamic aldehyde under the influence of light. G. BARGELLINI AND LYDIA MONTI. *Gazz. chim. ital.* **60**, 474–8(1930).—Reactions between quinone (I) and various aldehydes already described by Klinger (cf. *Ann.* **249**, 137(1888); **382**, 211(1911); *Ber.* **24**, 1340(1891); **31**, 1214(1898)), all of which followed the same course, suggested an analogous reaction with PhCH:CHCHO (II) and its derivs., which would constitute a method of formation of chalcones. The reaction proceeded otherwise, however, for by the action of light I was reduced to hydroquinone, II was oxidized to cinnamic acid (III), and these 2 products then combined, *i. e.*, the reaction is analogous to that between phenanthrenequinone and certain aldehydes (cf. Klinger, *loc. cit.*). I (10.8 g.) and II (13.2 g.) in C_6H_6 (100 cc.) exposed in a sealed glass tube to sunlight for 1 month (May-June), the insol. deposit steam-distd. to remove traces of I and II and the residue (10 g.) washed with SO_2 soln. and recrystd. repeatedly from dil. EtOH, yields *hydroquinone cinnamate*, *p*-HOC_6H_4OCOCH:CHPh (IV), yellowish, m. 172–3°, sol. in concd. H_2SO_4, it is repptd. from its cold dil. NaOH soln. by CO_2 or HCl, whereas it cannot be repptd. from its dil. NaOH soln. after the latter has been boiled. On exposure to air, alk. solns. of IV blacken. With I (2 mols.) and II, or with I and II (2 mols.), the reaction led only to IV as before. Control tests of the same mixts. kept in darkness showed no reaction. IV (5 g.), EtI (10 g.) and KOH (5 g.) in EtOH refluxed 5 hrs., evapd., the residue dissolved in water, extd. with Et_2O, the ext. evapd., and the residue recrystd. from dil. EtOH, yields *p*-$C_6H_4(OEt)_2$. The alk. soln. which has been extd. with Et_2O acidified, extd. with Et_2O, the ext. evapd. and the residue crystd. from boiling water yields III. IV (5 g.), AcONa (10 g.) and Ac_2O (50 cc.), refluxed 6 hrs., poured into water and the ppt. recrystd. from dil. EtOH, yields the *mono-Ac deriv.* *p*-$AcOC_6H_4OCOCH$:CHPh, yellowish, m. 121–2°, is reduced in

EtOH by H with Pd black, with formation of the compd. $C_{17}H_{16}O_4$, which, crystd. from dil. EtOH, m. 84–6°. C. C. DAVIS

Mercuration of β-resorcylic acid. REUBEN B. SANDIN AND JACOB M. ZEAVIN. *J. Am. Chem. Soc.* **52**, 4369–72(1930).—β-Resorcylic acid and $Hg(OAc)_2$ in hot glacial AcOH, heated a few min. and poured into H_2O, then dried at 100° for 12–24 hrs., give 95% of the *anhydro-5-hydroxymercuri deriv.*, which gives with I in AcOH 5,2,4-I(HO)$_2$-$C_6H_2CO_2H$. An excess of $Hg(OAc)_2$ in EtOH-AcOH gives 95% of the *anhydro-3-hydroxymercuri-5-acetoxymercuri deriv.* results; I gives the 3,5-di-I deriv. In alk. soln. there results 80% of *anhydro-3,5-dihydroxymercuri deriv.*, brown. The color of the anhydro derivs. indicates the possibility of quinoid structure. C. J. WEST

Mellitic acid and its derivatives. HANS MEYER AND HARRY RAUDNITZ. *Ber.* **63B**, 2010-8(1930); cf. *C. A.* **8**, 3032.—Mellitic acid (I) is obtained in the following % yields: from Bohemian graphite ground in a Plauson colloid mill, 10; yellow graphitic acid (1.3 g. SiO_2 and 0.5 g. $Fe(OH)_3$ in 8.5 g.) 50; Staudenmayer and ordinary pyrographitic acid, 35; beechwood charcoal ground in a colloid mill, 8; animal charcoal, 6; sugar charcoal, 26. An excellent raw material is the "Carboraffin" of the Aussiger Verein f. chem. u. metallurg. Produktion; the I can be obtained dependably in 32–40% yield as the NH_4 salt by slowly adding 200 g. of the charcoal to 1600 cc. HNO_3 (d. 1.5–1.52), heating 24 hrs. on the H_2O bath, refluxing 70–80 hrs. with 0.2% vanadic acid, adding 100–200 cc. concd. HNO_3 and boiling until the soln. is light yellow (if the soln. is still dark after 20 hrs., 100 cc. concd. H_2SO_4 is added and the boiling is continued). The soln. is evapd. and, if no H_2SO_4 has been used, the residue is powd. and dried at 125° until free of HNO_3; if H_2SO_4 was used the soln. is concd. until foaming ceases and the I is pptd. with H_2O. The crude I is converted into the NH_4 salt and purified through the cryst. light green *Cu salt*. *Phenolmellitein*, from I, PhOH and $SnCl_4$ at 115–20°, reddish yellow sandy powder, sol. in alkalies with blood-red color, also sol. in concd. H_2SO_4, alc., Et_2O and AcOEt; its action on the surviving small and large intestine of the cat is quantitatively the same as that of phenolphthalein. *Pyrogallolmellitein* (II), from I and pyrogallol at 160°, blue-black amorphous powder sol. in alkalies with dark violet, in concd. H_2SO_4 with deep brown color, gives with Me_2SO_4-KOH a *hexapyrogallolmellitein dodecamethyl ether*, light brown powder insol. in H_2O and alkalies, sol. in H_2SO_4 with brown color. In H_2SO_4 at 190°, II yields *mellitcerulein*, black powder sol. in KOH with corn flower-blue color. Mellitic trianhydride (III) is readily obtained from I with AcCl in sealed tubes at 120° or with boiling Ac_2O, and the dianhydride with $SOCl_2$ (or with Ac_2O if the boiling is limited to 0.5 hr.). III, if pure, is readily converted by $AlCl_3$ and C_6H_6 at 90–5° into *tribenzoylbenzenetricarboxylic acid*, faintly yellow hydrated powder, giving with boiling $SOCl_2$ the *pseudotrichloride*, m. 239° (the true *trichloride*, prepd. with PCl_5, is a brown viscous oil); *tri-Me ester*, amorphous powder. The anhydride and *p*-$C_6H_4(OH)_2$ stirred with Na-$AlCl_3$ at 200° yielded a black *hexahydroxyanthratriquinone*, sol. in H_2SO_4-H_3BO_3 with blue color and characteristic absorption bands at 665, 605, 565μμ, and forming a brownish yellow acetate. *Phenolpyromellitein* (IV), from pyromellitic acid, PhOH and $SnCl_4$ at 115–20°, faintly pink powder holding approx. 2 mols. H_2O at 140°, decomps. above 180°, behaves toward alkalies and H_2SO_4 like phenolphthalein, insol. in dil. acids; *tetraacetate*, insol. in Na_2CO_3, sol. in hot KOH; *tetra-Me ether*, yellowish white powder, m. below 100°, insol. in alkalies, rapidly hydrolyzed by concd. H_2SO_4; *tetra-Et ether*, yellowish; *octa-Br deriv.*, from IV in boiling alc. slowly treated with Br in AcOH, faintly yellowish powder easily sol. in alkalies with violet-blue, in H_2SO_4 with red color; excess of Br gives a yellowish powder contg. approx. 16 atoms of Br. III gives with high-boiling solvents intense colors due to the formation of mol. compds. (1:1), a large no. of which have been isolated. The dianhydride also forms such compds. but they can be isolated only if the solvent (like $PhNO_2$) does not boil too high; otherwise the dianhydride changes into III. In this way it was shown also that I itself is partly dehydrated in solvents of a sufficiently high b. p. The colors produced by III with some 60 substances are listed. The *naphthalene compd.* forms orange-red, the *anthracene compd.* dark blue, the *phenanthrene compd.* brick-red and the *veratrole compd.* light brown crystals. C. A. R.

The diterpenes kaurene and mirene. J. R. HOSKING. *Rec. trav. chim.* **49**, 1036–9 (1930).—Up to the present moment 11 diterpenes have been found in essential oils but only for α-camphorene is the C skeleton known (Ruzicka and Stoll, *C. A.* **18**, 1829). According to Kondakov and Saprikin (*C. A.* **20**, 3453) the naturally occurring diterpenes should be hydrogenated $C_{10}H_8$ or phenanthrene derivs. and therefore both the cryst. diterpenes kaurene and mirene were investigated more closely. The hydrogenation of kaurene with Pt black in AcOEt at room temp. or with Pt oxide in AcOH gives *dihydrokaurene*, m. 86–7°, d_4^{106} 0.9282, n_D^{100} 1.4912; the dihydro compd. does not give

any color with $C(NO_2)_4$ in $CHCl_3$ nor does it take up any more H on prolonged hydrogenation, even after reactivation of the catalyst according to Willstätter. In the same way mirene was converted into *dihydromirene*, m. 73–4°, which behaves also as a completely satd. compd. It thus follows that kaurene and mirene contain only 1 double bond and that a system of 4 C rings is present. On heating kaurene with its own wt. of Se at 340–50° during 30 hrs. 50% of a hydrocarbon, m. 79–81°, was obtained together with an oil, which, on repeated treatment with Se, gave a 2nd crop of the same hydrocarbon. The latter could be identified as *pimanthrene* by the m. p. of the *picrate*, 130–1°, and of the *styphnate*, m. 157–8°, as well as by the formation of a red quinone, m. 166°, by oxidation with CrO_3, the quinone and other derivs. being identical with the derivs. from pimanthrene, obtained by dehydrogenation of *d*-pimaric acid (Ruzicka and Balas, *C. A.* **17**, 3026) and of agathenedicarboxylic acid (Ruzicka and Hosking, *C. A.* **23**, 3711). C. F. VAN DUIN

Dependence of optical rotatory power on chemical constitution. VIII. Stereoisomeric (*d*-, *l*- and *dl*)*p*-phenylene-, 1,4-naphthylene-, *p,p'*-diphenylamine-, *p,p'*-diphenylmethanebisiminocamphors, *p*-phenylene-, *p,p'*-diphenylmethanebisaminocamphors, *p*-diphenylamineiminocamphors and *p*-diphenylamineaminocamphors and their derivatives. BAWA KARTAR SINGH AND BHUTNATH BHADURI. *J. Indian Chem. Soc.* **7**, 545–74(1930); cf. *C. A.* **24**, 4968.—In reducing the imino to amino compds. there is an enormous decrease in optical rotatory power. The influence of solvents shows that optical rotatory power does not in any case run parallel to the dielec. consts. of the solvents. The rotatory dispersion of Ac derivs. of *p,p'*-diphenylaminebisiminocamphors, of *p*-diphenylamineaminocamphors in all solvents tried and of *p*-diphenylaminocamphors in all solvents except pyridine is simple but others are complex or anomalous. The phys. identity of enantiomers is experimentally proved. By the m.-p. method some of the *dl*-forms are shown to be compds., some mixts. A. P. SACHS

Bromine derivatives of some polyphenols. G. GALLAS AND M. ALONSO. *Anales soc. espan. fis. quim.* **28**, 967–1002(1930).—Oxidation of PhOH and naphthols by $FeCl_3$, $KMnO_4$, etc., appears to link the 2 nuclei in the *o*- or *m*-, but not the *p*-position. *o,o'*-Biphenol, like *o,o'*-binaphthol, is difficult to purify and exact phys. consts. are lacking. Bromination of the 2 biphenols is easy, the *p*- more so than the *o*-compd., whose Br derivs. are likewise difficult to purify. Cold bromination is at times the max. possible. In other cases the deriv. corresponds to the amt. of Br used. The Br is in the *o*- or *p*-position to the OH. The Br derivs. can be oxidized as easily as the original compds., giving quinones of intense color. Condensation reactions are varied. Like the diphenols, the mol. can be broken by certain reducing agents. Alkalies replace Br, giving new polyphenols. Sepn. is incomplete. E. M. SYMMES

Stereochemical study of biphenyl-2,2'-disulfonic acid. VIII. W. M. STANLEY AND ROGER ADAMS. *J. Am. Chem. Soc.* **52**, 4471–6(1930); cf. *C. A.* **24**, 4014.—On the basis of x-ray data there is a possibility of the resolution of $(2\text{-}HO_3SC_6H_4)_2$; however, this was found impossible, from which it appears that the SO_3H group is not sufficiently large to interfere with a H atom and prevent free rotation; it is also possible that the SO_3H group may have a more compact structure than was supposed or the H atom may be smaller as a blocking group than has previously been assumed. The *brucine salt* of $(2\text{-}HO_3SC_6H_4)_2$, m. 245–8°, $[\alpha]_D^{20}$ —33.2°; the *quinine salt*, m. 191–3°, $[\alpha]_D^{20}$ —85.9°; the *morphine salt*, m. 261–7°, $[\alpha]_D^{20}$ —74.6°. Fractionation of these salts from several different solvents gave no indication of resolution. The 4,4'-di-NH_2 deriv. yields a *strychnine salt*, m. 310–8° (decompn.), $[\alpha]_D^{20}$ —22.4°; *brucine salt*, m. 311–4° (decompn.), $[\alpha]_D^{20}$ —20°; these could not be resolved. C. J. WEST

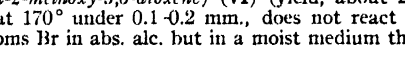
Mixed catalysts in the Friedel and Crafts reaction. Yield of benzophenone from benzoyl chloride and benzene using ferric chloride-aluminum chloride mixtures as catalysts. W. A. RIDDELL AND C. R. NOLLER. *J. Am. Chem. Soc.* **52**, 4365–9 (1930).—The yield of Ph_2CO prepd. from BzCl and C_6H_6 with $FeCl_3$-$AlCl_3$ is approx. the mean of that obtained using pure $FeCl_3$ and pure $AlCl_3$. The $FeCl_3$ has a detrimental action which is apparently due to the acceleration or inauguration of an unknown side reaction. The results are given as curves. C. J. WEST

Synthesis of cyclic compounds. VII. Stereoisomeric β,γ-diphenyl-adipic acids. MARIAM P. OOMMEN AND ARTHUR I. VOGEL. *J. Chem. Soc.* 1930, 2148–54; cf. *C. A.* **24**, 3225.—Reduction of 100 g. PhCH:$CHCO_2Me$ with 150–200 g. moist Al-Hg (cf. Henle, *Ann.* **384**, 16(1906)) gives 30–5 g. $PhCH_2CH_2CO_2H$, 22–3 g. of Me *meso*-β,γ-diphenyladipate (I) and 15–6 g. of the *dl*-ester (II). I m. 175°; hydrolysis gives the free acid, m. 270–1°, which could not be resolved by brucine, strychnine or quinine. *Et ester* m. 116°. The *acid chloride* m. 187°. II m. 73–4°; hydrolysis gives the *dl*-

acid, m. 185–6°. The action of Ac_2O on the 2 acids is described, the products resembling those obtained by H. The *dl*-acid was resolved by means of the brucine salt. The *d-acid* m. 200–1°, $[\alpha]^{20}_D$ 14.36° (*c* 3.09 in abs. EtOH); the *l-acid* is found in the more sol. fraction; the soly. of the *d*- and *l*-acids is greater than that of the *dl*-acid.
C. J. WEST

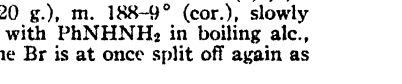
Reaction between triphenylmethyl, magnesium and a small amount of magnesium halide. The composition of the Grignard reagent. W. E. BACHMANN. *J. Am. Chem. Soc.* **52**, 4412–3(1930).—A small quantity of MgI_2 or $MgBr_2$ can suffice to convert Ph_3C and Mg to the Mg deriv. of Ph_3C. The reaction takes place in 2 steps: $2Ph_3C + Mg + MgX_2 = 2Ph_3CMgX$; $2Ph_3CMgX = MgX_2 + Ph_3CMgCPh_3$. The latter step makes the MgX_2 available for continuous reaction.
C. J. WEST

Superacid solutions. IV. Determination of the strength of weak bases and pseudo bases in glacial acetic acid solution. J. B. CONANT AND T. H. WERNER. *J. Am. Chem. Soc.* **52**, 4436–50(1930); cf. *C. A.* **22**, 4035.—A spectrophotometric study has been made of the acid-base equil. in solns. of crystal violet in buffered glacial AcOH solns. The extinction coeff. was measured at intervals of 10 mμ from 470 to 680. Data are given for the fundamentals chosen for the violet, green and yellow forms; also for the dissocn. consts. of crystal violet from spectrophotometric data at 25° in urea-H_2SO_4, urea-$HClO_4$ and acetoxime-H_2SO_4 buffers. The change of pK'_1 for crystal violet with change in ionic strength is shown in the form of curves; this effect is very marked; the total change of pK'_1 from the limiting value at $\mu = 0$ to $\sqrt{\mu} = 0.5$ is about 2.6 p_H units. In the more concd. solns. there are sp. effects depending on the nature of the neutral salt. These effects are larger than the corresponding effects in H_2O because of the low dielec. consts. of AcOH; the natures of both the cation and anion of the neutral salt are important. An electrometric study of weak bases and pseudo bases in glacial AcOH reveals the large effect of changing ionic strength, also noted in the spectrophotometric study. The following apparent pK' values for pseudo bases at 25° in glacial AcOH are reported (bases in 0.05 *M* soln. titrated with H_2SO_4 $\mu = 0.2$ with $Me_3NHSO_3C_6H_4Ne$-*p*): Ph_3COH —1.47; $C_{10}H_7CPh_2OH$ —1.25; $(MeOC_6H_4)_2CHOH$ —1.14; $MeOC_6H_4CPh_2OH$ —0.59; phenylxanthanol 1.91; dinaphthoxanthanol 2.40 $(MeOC_6H_4)_3COH$, 2.56. The effect of added H_2O on the apparent consts. of a no. of weak pseudo bases is reported. A method is outlined for obtaining significant values for the relative basicity of the "halochromic carbinols."
C. J. WEST



Chlorophenol red. WILTON C. HARDEN. *J. Am. Chem. Soc.* **52**, 4611(1930).—Repeated crystn. of chlorophenol red by soln. in hot H_2O, acidifying with HCl and concg. to the point of crystn., gives a sample with 7.60 S and 16.60% Cl; it forms small, fine, greenish-brown crystals and gives an entirely different color in buffer solns. than samples heretofore examd. The alk. color, besides being much more intense, contained more blue and less red than the com. samples.
C. J. WEST

Quinonoid structure of some triphenylmethyl salts. LEIGH C. ANDERSON. *J. Am. Chem. Soc.* **52**, 4567–72(1930).—The quant. absorption spectra of Ph_3COH, Ph_3CCl, $(Ph_3C)_2SO_4$ and Ph_3CClO_4 in Me_2SO_4 and of Ph_3CSO_4H and Ph_3CClO_4 in H_2SO_4 and $HClO_4$, resp., are reported. The data obtained from the absorption spectra of these salts constitute evidence in favor of the hypothesis that the sulfate, acid sulfate and perchlorate exist in a quinonoid modification in their solns. in Me_2SO_4, H_2SO_4 and $HClO_4$, resp.
C. J. WEST



Oxidation processes. III. Oxidation of α-ketoles with Fehling solution. ARNOLD WEISSBERGER, WALTER SCHWARZE AND HEINRICH MAINZ. *Ann.* **481**, 68–80(1930); cf. *C. A.* **24**, 3236.—The oxidation of benzoin by alk. Cu tartrate is unimol. and the reaction velocity is proportional to the concn. of free alkali, *i. e.*, alkali in excess of the 2 mols. concerned in forming the $Cu(OH)_2$ complex; the velocity is independent of the concn. of Cu salt and is, therefore, not a measure of the direct reaction with the oxidizing agent. It is suggested that the slowest phase of the complete reaction (*i. e.*, that detg. the velocity) is the transformation of the ion —OCHPh.COPh into the ion of stilbenediol —OCPh:CPhOH, and this is confirmed by the small differences observed in the resp. velocities of oxidation by Fehling soln. and of autoxidation, where large concn. differences of the available oxidizing agents obtain. The effect of substituents follows the same rule as in the case of autoxidation, the rate of oxidation with Fehling soln. thus also being related to the electrolytic dissocn. of the ketole.
C. J. WEST

Cycloacetals of benzoin and their rearrangement. MAX BERGMANN AND GEORG WEIL. *Ber.* **63B**, 1911–7(1930).—Fischer obtained quantitatively from benzoin (I) and MeOH-HCl an ether (II) which, since it can still form an oxime, must have the structure PhCOCH(OMe)Ph. From what is known of the chemistry of hydroxy-

cyclohexanone, such ethers are not formed directly from the HO ketones but through the dimol. lactolides (cycloacetals) by rearrangement. Cycloacetals of I were not known up to the present, however. According to Irvine and his collaborators the action of MeOH-HCl on I is quite complicated, giving considerable amounts of 2 compds., $C_{29}H_{24}O_3$ (III) and $C_{30}H_{28}O_4$ (IV); III with HCl gives I and II, but IV cannot be converted into either I or II. Since both III and IV yield tetraphenylfuran with fuming HI, Irvine and McNicoll assigned furoid structures to them and concluded that they play no role in the formation of II. B. and W. have now established, however, that IV is the dimol. *Me cycloacetal* (V) of I; hot *N* HCl converts it practically quantitatively into I in a few min. if a little PhOH is added to facilitate its soln., and, on the other hand, it yields II almost quant. with MeOH satd. with HCl. To III is assigned the structure VI of an unsatd. cycloacetal; like V, it can be converted quantitatively into II and with O_3 it yields PhCOCH(OBz)Ph and BzOH. The structure VI also explains the observation that with Br in aq. solvents are obtained about equal parts of Bz_2 and I. The difference between the results of Fischer and of Irvine is due to the fact that with about 30% HCl in MeOH both V and VI are readily obtained but with highly satd. HCl-MeOH (50%) they are completely changed into II. The structure VI is also supported by a series of further reactions, especially catalytic reduction; with Pd sponge as catalyst, the reduction does not stop with satn. of the double bond but all the O is reduced away; a similar reduction can be effected with I and II but the yield of $(CH_2Ph)_2$ is not as large. With hot aq. *N* HCl in the presence of PhOH, VI is completely hydrolyzed in a few min., yielding, not I like V, but about equimol. amounts of Bz_2 and $PhCOCH_2Ph$, together with other substances. This, therefore, is a case of an oxidation-reduction in which VI represents the dimol. intermediate product. *Dibenzoin bis(methyl lactolide)* (*2,3,5,6-tetraphenyl-2,5-dimethoxydioxane*) (V), obtained in 30–5 g. yield from 100 g. I, m. 296° (cor.) (I. gives 285°), slowly sublimes at 200° under 0.2 mm., mol. wt. (Bleir-Kohn) 473–83. *Anhydrodibenzoin Me lactolide* (*2,3,5,6-tetraphenyl-2-methoxy-5,6-dioxene*) (VI) (yield, about 20 g.), m. 188–9° (cor.), slowly sublimes at 170° under 0.1–0.2 mm., does not react with $PhNHNH_2$ in boiling alc., adds 2 atoms Br in abs. alc. but in a moist medium the Br is at once split off again as HBr.

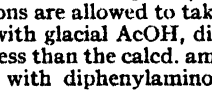
C. A. R.

Reduction of *p*-dimethylaminobenzil. SANFORD S. JENKINS, JOHANNES S. BUCK AND LUCIUS A. BIGELOW. *J. Am. Chem. Soc.* **52**, 4495–9(1930).—*p*-$Me_2NC_6H_4COBz$, further reduction in abs. EtOH gives 90% of *p-dimethylaminohydrobenzoin* (II), m. 112° (all m. ps. cor.). Heating II with AcOH-HCl gives 70% of *α-p-dimethylaminodesoxybenzoin* (III), m. 128° (*oxime*, m. 139°). I with Sn and HCl gives a mixt. of *β-p-dimethylaminodesoxybenzoin* (IV), m. 164° (*oxime*, m. 142°) and III. Catalytic reduction of III gives *α-p-dimethylaminostilbene hydrate*, m. 78°, while IV gives the *β*-isomer, m. 60° (Sachs and Sachs, *Ber.* **38**, 515 (1905)). Heating either form with AcOH and HCl gives *p*-$Me_2NC_6H_4CH{:}CHPh$, m. 148°, reduced to *p-dimethylaminodiphenylethane*, m. 63°; the *methiodide* m. 260–2° (uncor.). C. J. WEST

Rearrangements of brominated naphthalenes by aluminum chloride. H. LOHFERT. *Ber.* **63B**, 1939–41(1930).—As is well known, reactions in the presence of $AlCl_3$ cannot be used for detg. constitutions because $AlCl_3$ readily brings about migrations of the substituents. No such rearrangements had hitherto been observed with the dihalogenonaphthalenes, but L. came across such a case in attempting to convert 1,2-$C_{10}H_6Br_2$ with AcCl and $AlCl_3$ in CS_2 into aceto-1,2-dibromonaphthalene (I). The desired I (m. 146°) was formed only in small amount; the products were, depending on the conditions, either 1,4-$C_{10}H_6Br_2$, m. 83° (20–30% yield), and I, or 1,5-$C_{10}H_6Br_2$, m. 131° (50% yield) and unchanged 1,2-$C_{10}H_6Br_2$. The AcCl plays a role in the reaction only through the HCl formed from it, *i. e.*, the rearrangement can be effected with $AlCl_3$ and HCl alone. It suffices to pass dry HCl into the boiling CS_2 soln. contg. $AlCl_3$ in suspension to bring about the migration of the *β*-Br atom to the *α*(5)-position or the *α*-Br atom to the *β*(6)-position. In most cases was formed 2,6-$C_{10}H_6Br_2$, in a few cases only 1,5-$C_{10}H_6Br_2$. Attempts to direct the Br atoms to the *α,α*- or *β,β*-positions by varying the conditions were without success. C. A. R.



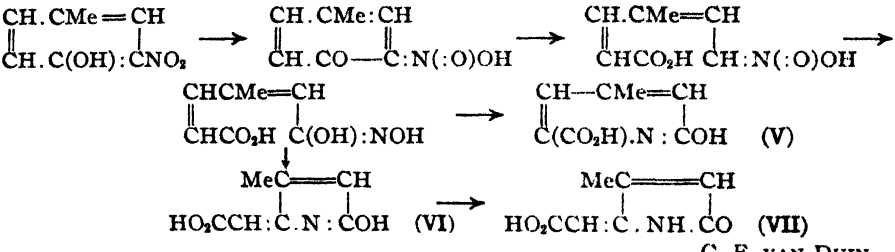
Preparation of 1-naphthoic nitrile from 1-naphthylamine. JOHN A. MCRAE. *J. Am. Chem. Soc.* **52**, 4550–2(1930).—Contrary to the statement of Whitmore and Fox (*C. A.* **24**, 106), 1-$C_{10}H_7CN$ may be obtained in 25–35% yields from 1-$C_{10}H_7NH_2$

by the Sandmeyer reaction. The Korczynski method (*C. A.* **14**, 2919; **21**, 77) did not give sensibly greater yields than the ordinary Sandmeyer process, but by adding the acid diazo soln. to KCN-$Ni(CN)_2$ contg. sufficient alkali to neutralize the free acid of the diazo soln., the nitrile has been obtained in yields of 58–60%. Exptl. details are given. C. J. West

Anthraquinone derivatives as precipitants for bases. Walther Zimmermann. *Z. physiol. Chem.* **192**, 124–30(1930).—Sulfonic acids of anthraquinone and several of its OH derivs. were examd. as precipitants for alkaloids and various bases of natural occurrence. The cryst. products described and analyzed are *guanidine alizarindisulfonate*, m. 259°, *creatinine anthrarufindisulfonate*, m. 333° (decompn.), *creatine anthrarufindisulfonate*, m. 310° (foaming), *lysine purpurinmonosulfonate*, decomps. 249°, *putrescine purpurinmonosulfonate*, m. 258°. A. W. Dox

Purification of phenanthrene. Frank L. Cohen and Ulysse Cormier. *J. Am. Chem. Soc.* **52**, 4363–4(1930).—Crude phenanthrene (I) (5 kg.), dissolved in 12 l. 95% EtOH and cooled to 15°, gives 4–4.3 kg. gray material, m. 105–10°: 1 kg. of this product in 6 l. EtOH, treated with 120 g. concd. HNO_3 and refluxed 1.25–1.5 hrs., gives 800–900 g. of red flakes, m. 93–6°; distn. at atm. pressure and recrystn. from EtOH gives 30–45% pure I (based on the crude I); over 80% of the solvent can be recovered. C. J. West

Action of hydrazides. IV. Condensation of diarylaminoguanidines with phenanthraquinone and some of its derivatives. Satish Chandra De and Devendra Nath Dutt. *J. Indian Chem. Soc.* **7**, 537–44(1930); cf. *C. A.* **24**, 4781.—The object of D. and D. was to det. the effect of diminishing the basicity of the amino group in the $-C(:NH)NH_2$ of aminoguanidine by certain aryl substitution products as regards the action on phenanthraquinones. When the monoxime of phenanthraquinone or its substitution products is condensed with the various diarylaminoguanidines in alc. the hydrazone oximes are formed in good yield by the elimination of a mol. of water. When the same reactions are allowed to take place in glacial AcOH, or when the hydrazone oximes are heated with glacial AcOH, different products are formed. These compds. contain 2 atoms of N less than the calcd. amt., elemental N having been evolved. Phenanthraquinone (I) reacts with diphenylaminoguanidine (II) in alc. to form phenanthraquinone-diphenylaminoguanidine (III) m. 240°. The monoxime of III, m. 158°, on heating in AcOH for 4–5 hrs., yields a product m. 180° (decompn.), which analyzes for $C_{27}H_{18}N_2$. This would indicate a loss of $HONH_2$ and N_2 from the oxime. The formula suggested is



The loss of $HONH_2$ and N_2 seems rather consistent throughout the series studied. 2-Nitrophenanthraquinone (IV) with II gives the 2-nitro deriv. of III, m. 238°, whose oxime, m. 233°, decomps. as indicated above after heating in AcOH for 6 hrs. giving a compd. m. 193°. The corresponding 2,7-dinitro compd. m. 235°, and yields an oxime, m. 245°, which decomps. in AcOH and then m. 202°. I with di-*p*-tolylaminoguanidine (V) in alc. gives a compd. m. 236°, yields an oxime, m. 227°, which decomps. on heating 6 hrs. in AcOH to lose the equiv. of CH_3ON_3, and then m. 156°. IV with V in alc. forms a compd. m. 228°, and its oxime is also reported as m. 228°, but the N increased from 14.55 to 16.82%. Heating 6 hrs. in AcOH caused the oxime to lose CH_3ON_3; the product m. 190°. The corresponding 2,7-dinitro compd., m. 263°, yields an oxime, m. above 300°, which loses CH_3ON_3 in AcOH and then m. 223°. I with di-β-naphthylaminoguanidine (VI) forms a compd. m. 240°, yields an oxime, m. 235°, which loses H_3ON_3 in AcOH, and m. 245°. IV with VI, forms a compd. m. 200°. The 2,7-dinitro compd. m. 270°. Anal. data are given for all compds. reported. John B. Entrikin

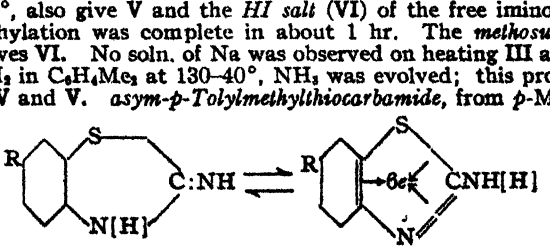
Chemistry of furfural. Preparation of tetraethyldiaminodiphenylfurylmethane hydrochloride and of diphenylfurylmethane. S. A. Mahood and Helen F. Aldrich. *J. Am. Chem. Soc.* **52**, 4477–80(1930).—$PhNEt_2$, furfural and $ZnCl_2$, heated at 100° for 11 hrs., give 31% of the *leuco base* of *tetraethyldiaminodiphenylfurylmethane*, light yellow, m. 78°; oxidation with PbO_2 in acid soln. gives the *HCl salt*, dark green, dyes silk a yellower color than malachite green and in the lighter tones gives a clear bright green; the dyed samples are fast to washing but fade on exposure to light. Diphenylfurylcarbinol, obtained in 85% yield from PhMgBr and Et pyromucate, on reduction with Zn in AcOH at 70° gives 95% of *diphenylfurylmethane*, m. 51° (cor.). C. J. West

The by-product from the action of concentrated sulfuric acid on 3-nitro-4-hydroxy-

toluene. I. J. RINKES. *Rec. trav. chim.* **49**, 1002–5(1930).—Pauly, Gilmour and Will (*C. A.* **8**, 1736) and Pauly and Will (*C. A.* **13**, 573) have shown that the chief product of the action of concd. H_2SO_4 on 3,4-$O_2N(HO)C_6H_3Me$ is the semi-lactone of β-methylmuconic acid. To the extent of 5% of the wt. of the starting material a by-product is obtained which is considered by these investigators to be a γ-methyl-α-pyridone-α′-carboxylic acid. This product should be formed by ring closure by the N atom combining with the C atom in position 5, but it may be assumed with equal justification that the C atom 6 is involved in this process. Doubt was thrown on the accuracy of the pyridine formula on account of the very poor yields of decarboxylated product obtained by the removal of CO_2 while pyridinecarboxylic acids as a rule give excellent yields in this reaction. In order to differentiate between the 2 formulas the amide of VII was broken down with NaOCl in MeOH; if the pyridine formula V be correct an aminopyridine deriv. should be produced but if the pyrroline formula VII be correct, an aldehyde should be obtained as follows: $RCH{:}CHCONH_2 \longrightarrow RCH{:}CHNHCO_2Me \longrightarrow RCH_2CHO$. The latter reaction appeared to take place and this result could be confirmed by the oxidation of the acid VII, citraconimide being obtained. The acid VII was first converted into its Me ester in the usual way and then into the amide, m. 214°, with concd. ammonia at 5°, the latter reaction being complete in 7–8 days. The suspension of this amide in MeOH was treated with NaOCl soln. at −5°, yielding *Me 2-keto-4-methyl-Δ³-pyrroline-5-methinecarbamate*, m. 187–8°, which on sapon. with $Ba(OH)_2$ and evapn. of the filtrate *in vacuo*, gave a soln. which immediately gave cryst. ppts. with *p*-$O_2NC_6H_4NHNH_2$ in 50% AcOH or with semicarbazide, thus proving the presence of a C:O group. The oxidation of the acid VII with the calcd. amount of CrO_3 (3 atoms of O) at 40° gave citraconimide, m 107–8°, by repeated extn. of the reaction mixt. with ether; it was identical with an authentic specimen, prepd. from citric acid. These results prove that the by-product from the action of concd. H_2SO_4 on 3,4-$O_2N(HO)C_6H_3Me$ is to be considered as *2-keto-4-methyl-Δ³-pyrroline-5-methincarboxylic acid.*

C. F. VAN DUIN

Action of Grignard reagent on *N*-methylpyrrolidone. New synthesis for substituted pyrrolines. R. LUKEŠ. *Collection Czechoslov. Chem. Comm.* **2**, 531–44(1930).—*N*-Methylsuccinimide and H_2SO_4 are electrolyzed at 15° and 0.1 amp./cm.². Pptn. of H_2SO_4 by $Ba(OH)_2$, filtration, drying *in vacuo*, distn. at 85° and 15 mm. gives *N*-methylpyrrolidone (I), b. 200–1°, $d_4^{9.8}$ 1.0450, $n_D^{9.8}$ 1.47118. I with 2MeMgBr, after being decompd. with H_2O and made alk. with $Ba(OH)_2$, is steam distd. The distillate is made acid with HCl. The aq. layer is evapd. *in vacuo*, added to alc. $NaClO_4$, filtered and crystd. The crystals are decompd. by NaOH, dissolved in Et_2O, dried over NaOH and distd. at 45 mm. and 56–7°. The product, 1,2-dimethyl-Δ²-pyrroline, b. 120–30° in H_2 atm.; the picrate m. 238°; the $HAuCl_4$ salt m. 135°, 182° or 200°. The mother liquor from the $HClO_4$ treatment is made alk. with NaOH and distd. Alc. picric acid gives a picrate which is dissolved in H_2O, acidified with HCl, shaken twice with $PhNO_2$, once with Et_2O, evapd. to a sirup, treated with NaOH, extd. with Et_2O, dried and distd. The 1,2,2-trimethylpyrrolidine b. 130–5°. In the same way is prepd. 1-methyl-2-ethyl-Δ²-pyrroline, b_{10} 40–1° in H_2, d_4^{11} = 0.8779, n_D^{11} 1.49452; its $HClO_4$ salt m. 209°; its $HAuCl_4$ salt m. 115–7°; 1-methyl-2,2-diethylpyrolidine b. 168°; its H_2PtCl_6 salt m. 235°; its $HAuCl_4$ salt m. 159–63°; 1-methyl-2-propyl-Δ²-pyrroline b_{30} 82°; $HClO_4$ salt; 1-methyl-2,2-dipropylpyrrolidine b_{738} 206.8°; its picrate m. 130°; 1-methyl-2-phenyl-Δ²-pyrroline, b_{16} 112° in H_2, d_4^{11} 1.0083, $n_D^{11.4}$ 1.57578; its HCl salt m. 96°; its $HClO_4$ salt m. 117–8°; its $HAuCl_4$ salt with 1 mol. H_2O, m. 95–7°; and its picrate, m. 140–1°, have also been prepd.



V. F. HARRINGTON

Constitution of metallic complexes of indigo coloring matters. HANS MACHEMER. *J. prakt. Chem.* **127**, 109–68(1930); cf. *C. A.* **24**, 4297.—An extensive review is given of

the previous work on metallic complexes of indigotin and related coloring matters with special reference to their constitution. The absorption bands, 607, 605 and 591$\mu\mu$, of indigotin (I) in C_5H_5N, $CHCl_3$ and $C_6H_4Me_2$, resp., disappear on shaking solns. of indigotin with dry metallic acetates at the ordinary temp. but reappear on addn. of small quantities of acid or of alc. When I is treated with $Cu(OAc)_2$ in dry $C_6H_4Me_2$ at 100° or in dry C_5H_5N soln., the Cu complex is formed and 2 mols. AcOH are eliminated. The Fe^{++} complex of I is formed by reaction between $Fe(OAc)_2$ and I in dry C_5H_5N in dry N atm. I reacts with MeOH-NaOH at room temp. to give the *compd.* $C_{16}H_{10}O_2N_2.NaOH$; shaking the soln. for 12 days there results the *compd.* $C_{16}H_9O_2N_2Na.NaOH$. Et indigotinmalonate yields complexes with *Cu*, *Ag* and $SnCl_4$ ($C_{21}H_{13}O_4N_2.SnCl_3$), bluish black. Indigotinphenyl acetate, $Cu(OAc)_2$, and concd. NH_4OH in C_5H_5N and EtOH give the *Cu complex*. Desoxyindigo with $SnCl_4$ in PhMe gives the complex, $C_{16}H_{11}ON_2.SnCl_3$, deep black-green. 1-Naphthalene-2-indoleindigo yields a *Cu complex*, $C_{36}H_{20}O_4N_2Cu$, blue-black; *Co complex*, blue-black; *$SnCl_3$ complex*, black. 2-Naphthalene-2-indoleindigo yields a *$SnCl_3$ complex*, whose C_5H_5N soln. is green. 3-Hydroxybenzene-2-indoleindigo gives a *$SnCl_3$ complex*, black. 2-Thionaphthene-2-indoleindigo and $SnCl_4$ in $C_6H_4Me_2$ give the dark blue *$SnCl_3$ complex*. 1-Hydroxyanthraquinone in EtOH and a concd. metallic acetate soln. in 10–15% NH_4OH soln. give the *Cu* and *Co complexes;* heating with K in $C_6H_4Me_2$ at 150–200° gives the *K complex*. The anhydrophenylacetates of indigotinmalonic ester, of indigotinphenylacetate and of 2-naphthalene-2-indoleindigo form *mol. compds.* with $SnCl_4$; no metallic complex salts could be prepd. Indole does not react with finely divided Ag or Cu in dry C_5H_5N but reacts readily in C_5H_5N with metallic acetates in NH_4OH to give *complexes* with Ag ($C_{19}H_{15}N_2Ag$) and Cu; $Hg(OAc)_2$ gives the compd. $HgOH.C_{19}H_{15}N_2.2Hg(OAc)_2$. Indole, fuming HNO_3, $NaNO_2$ or $AmNO_2$ in AcOH give the *nitrate*, yellowish red, may be recrystd. from AcOH. Dil. H_2SO_4 in dil. HCO_2H gives the *sulfate*, carmine-red. A table gives the halochromic behavior of the indigoid dyes.

C. J. WEST

Unsaturation and tautomeric mobility of heterocyclic compounds. III. Effect of substituents on the mobility of the aminobenzothiazole system and on the bromination of *sym*-diarylthiocarbamides. Ultra-violet absorption of mobile and of static semicyclic amidines of the benzothiazole group. ROBERT FERGUS HUNTER AND JOHN WM. THOMAS JONES. *J. Chem. Soc.* 1930, 2190–213; cf. *C. A.* 24, 4036.—In a study of the tautomerism of substituted 1-aminobenzothiazoles with the object of ascertaining the effect of polar conditions on the behavior of sym. semicyclic triad systems, the 5-substituted bases (I $\rightleftharpoons$ Ia), in which the *p*-substituent to the nuclear N atom can act by virtue of electronic displacements partly similar to those which operate in aromatic substitution, were chosen as the starting point. *p*-$MeC_6H_4NHCSNHAc$ (II), m. 142°, treated with Br at 0° and reduced with H_2SO_3, gives *1-imino-2-acetyl-5-methyl-1,2-dihydrobenzothiazole*, yellow, m. 192°; heating with concd. HCl for 24 hrs. gives 1-amino-5-methylbenzothiazole (III) (I, R = Me). II and Br in $CHCl_3$, refluxed for a few min., give the *hydrotribromide*, $C_{10}H_{10}ON_2S.HBr.Br_2$, orange, m. 149° (decompn.); reduction gives the 1-Ac deriv. (IV) of III, m. 216°, identical with the acetylation product of III. III (5 g.) and Me_2SO_4 give an oil which, with Ac_2O, gives a mixt. of IV (1.15 g.) and *1-acetimido-2,5-dimethyl-1,2-dihydrobenzothiazole* (V), m. 168°. MeI and III, heated for 10 hrs. at 100°, also give V and the *HI salt* (VI) of the free imino base, m. 290° (decompn.); methylation was complete in about 1 hr. The *methosulfate* of III, m. 160°; satd. KI gives VI. No soln. of Na was observed on heating III and Na in $C_6H_4Me_2$; with $NaNH_2$ in $C_6H_4Me_2$ at 130–40°, NH_3 was evolved; this product with MeI gives a mixt. of IV and V. *asym-p-Tolylmethylthiocarbamide*, from *p*-MeC_6H_4NHMe.-

(I) (Ia)

HCl and KSCN in H_2O for 12 hrs., m. 109°; bromination in $CHCl_3$ and reduction with H_2SO_3, followed by acetylation, gives V. IV and Me_2SO_4, heated 10 min., give V. *sym-p-Tolylmethylthiocarbamide*, m. 126°, with Br in $CHCl_3$, gives the *hydrotetrabromide*, orange-red, m. 90° (decompn.), of *1-methylamino-5-methylbenzothiazole* (VII), m. 152°, obtained by treatment with H_2SO_3 and NH_3; heating the bromide in EtOH gives *3-bromo-1-methylamino-5-methylbenzothiazole* (VIII), m. 165°, whose structure was

established by the following synthesis. 3,4-$BrMeC_6H_3NH_2$, CS_2, EtOH and S, boiled for 5 hrs., give *sym-di-m-bromo-p-tolylthiocarbamide*, m. 163°. heating with Ac_2O for 2 min. gives *m-bromo-p-tolylthiocarbimide*, m. 53°; condensation with $MeNH_2$ gives *sym-m-bromo-p-tolylmethylthiocarbamide*, m. 162°; bromination in $CHCl_3$ gives **VIII**. Bromination of **VII** in $CHCl_3$ gives a *hydrotribromide*, red, m. 137° (decompn.), of **VIII**. The *Ac deriv.* of **VII** m. 162°. **III** and PhSCN in abs. EtOH give *sym-5-methylbenzothiazolylphenylcarbamide*, m. about 310°. *p*-$EtOC_6H_4(Ac)NCSNH_2$, m. 144°, and Br give a *hydrotetrabromide*, orange, m. 139° (decompn.), reduced to *1-imino-2-acetyl-5-ethoxy-1,2-dihydrobenzothiazole*, yellow, m. 147°; concn. HCl gives **III**. *p*-$EtOC_6H_4NHCSNHAc$ and Br in $CHCl_3$ give *1-acetamido-5-ethoxybenzothiazole*, m. 244°. 1-Amino-5-ethoxybenzothiazole and Me_2SO_4, heated 10 min., give *1-imino-5-ethoxy-2-methyl-1,2-dihydrobenzothiazole*, straw-colored, m. 147°. *sym-p-Ethoxyphenylmethylthiocarbamide*, m. 129°, yields with Br *1-methylamino-5-ethoxybenzothiazole*, m. 145°. *asym-Acetyl-p-bromophenylthiocarbamide*, m. 157°, isomerizes to the stable *sym-form*, m. 205°, at its m. p.; the action of Br on these compds. appears to be of an oxidizing nature, since H_2O_2 gives the same product, m. 234°, which is S-free. Methylation of 5-bromo-1-aminobenzothiazole gives 5-bromo-1-imino-2-methyl-1,2-dihydrobenzothiazole, m. 102–4°, whose Ac deriv. m. 219°. *asym-Acetyl-p-chlorophenylthiocarbamide*, m. 157°; the *sym-isomer* m. 186°; Br has an oxidizing action, giving a S-free compd., m. 227°. 5-Chloro-1-aminobenzothiazole (**IX**), Me_2SO_4 and then Ac_2O give *5-chloro-1-acetylimino-2-methyl-1,2-dihydrobenzothiazole*, m. 197°. *sym-p-Chlorophenylmethylthiocarbamide*, m. 214°, with Br gives the *1-McNH deriv.* of **IX**, m. 214° (*Ac deriv.*, m. 175°). Heating *p*-$O_2NC_6H_4NHCSNH_2$ and Br in $CHCl_3$ and reduction or nitration of 1-aminobenzothiazole (**X**) gives the *5-NO_2 deriv.* (**XI**) of **X**, orange, m. 243° (*Ac deriv.*, pale yellow, m. 292°). Methylation of **XI** gives *5-nitro-1-imino-2-methyl-1,2-dihydrobenzothiazole*, pale yellow, m. 167° (*Ac deriv.*, pale yellow, m. 292°), also obtained by direct nitration. *5-Nitro-1-methylaminobenzothiazole*, pale yellow, m. 272° (*Ac deriv.*, pale yellow, m. 241°), results by direct nitration. 1-Anilinobenzothiazole (**XII**) (*picrate*, yellow, m. 223°) and Me_2SO_4, heated 10 min., give a mixt. of *1-phenylmethylaminobenzothiazole*, isolated as the *picrate*, yellow, m. 185° (also obtained from 1-chlorobenzothiazole and PhNHMe) and *1-phenylimino-2-methyl-1,2-dihydrobenzothiazole picrate*, yellow, m. 223°. The 4'-Br deriv. of **XII** with Me_2SO_4 gives a *Me deriv.*, m. 105° (*picrate*, yellow, m. 242°). *p-Ethoxy-sym-diphenylthiocarbamide*, m. 148°, with Br in CS_2 gives *4'-ethoxy-1-anilinobenzothiazole*, m. 166°, also obtained from 1-chlorobenzothiazole (**XIII**) and *p*-$EtOC_6H_4NH_2$. *p-Nitro-sym-diphenylthiocarbamide*, pale yellow, m. 141°, with Br, or **XIII** and *p*-$O_2NC_6H_4NH_2$ give *4'-nitro-1-anilinobenzothiazole*, orange, m. 212° (*Ac deriv.*, pale yellow, m. 172°). *1-Chloro-5-methylbenzothiazole* (**XIV**), b_{15} 148–52°, is conveniently prepd. from **III** through the Sandmeyer reaction; with $PhNH_2$ there results the *1-anilino deriv.*, m. 158° (*picrate*, yellow, m. 216°). *1-Anilino-4'-methylbenzothiazole*, m. 177° (*picrate*, pale yellow, m. 238°). Bromination of *p*-$MeC_6H_4NHCSNHPh$ gave products m. 145–200°, from which neither of the expected anilinobenzothiazoles could be isolated. *sym-p-Ethoxyphenyl-p-tolylthiocarbamide*, m. 137°, with Br in $CHCl_3$ and the product shaken with H_2SO_3 gives *3-bromo-1-anilino-4'-ethoxy-5-methylbenzothiazole*, m. 156°. *p*-$EtOC_6H_4NH_2$ and **XIV** give *1-anilino-4'-ethoxy-5-methylbenzothiazole*, m. 171°. *sym-p-Bromophenyl-p-tolylthiocarbamide*, m. 187°, on bromination gives *4'-bromo-1-anilino-5-methylbenzothiazole*, m. 209° (*picrate*, yellow, m. 251° (decompn.)), also obtained from **XIV** and *p*-$BrC_6H_4NH_2$. *sym-p-Nitrophenyl-p-tolylthiocarbamide*, yellow, m. 175°, with Br gives *4'-nitro-1-anilino-5-methylbenzothiazole*, orange, m. 265°, also obtained from **XIV** and *p*-$O_2NC_6H_4NH_2$. *sym-p-Bromo-p'-ethoxydiphenylthiocarbamide*, m. 169°, with Br in $CHCl_3$ gives *4'-bromo-1-anilino-5-ethoxybenzothiazole*, m. 198°; if CS_2 is used and the heating is continued for 5 min., there results probably the *3,4'-di-Br deriv.*, m. 226°. *p*-$EtOC_6H_4NH_2$ and 1-chloro-5-bromobenzothiazole give the *1-anilino deriv.*, m. 199°. *sym-p-Chloro-p'-bromodiphenylthiocarbamide*, m. 187°, with Br in CS_2 gives *4'-chloro-5-bromo-1-anilinobenzothiazole*, m. 218°, also prepd. from *p*-$ClC_6H_4NH_2$. *sym-p-Bromo-p'-nitrodiphenylthiocarbamide*, yellow, m. 186°, with Br in $CHCl_3$ gives *5-bromo-4'-nitro-1-anilinobenzothiazole*, yellow, m. 259°. *p*-$BrC_6H_4NHCSNHPh$ and MeI in MeOH, refluxed 10 min., give the *S-Me deriv.*, m. 78°; further heating with MeI produces no change but Me_2SO_4 for 15 min. gives *S-methyl-sym-phenylmethyl-p-bromophenylthiocarbamide*, m. 93°. *p*-BrC_6H_4SCN and PhNMe give *sym-phenylmethyl-p-bromophenylthiocarbamide*, m. 156°; Me_2SO_4 gives the *S*-Me deriv. $CS(NH_2)_2$ and Br in EtOH give a Br deriv., m. 191° (decompn.); in CS_2 there results a *perbromide*, red, which evolves HBr on standing, giving the above Br deriv. Absorption spectra are given for **III**, **IV**, **V** and **XII**. The ultra-violet absorption curve of **XII**

in EtOH resembles the curves of III and IV at equimol. concns. for wave lengths between 2450 and 2700 A. U. and simulates the absorption curve of V from 2800 to 3300 A. U.

Isoxazoline oxides. X. Reduction. E. P. KOHLER AND A. R. DAVIS. *J. Am. Chem. Soc.* **52**, 4520–8(1930); cf. *C. A.* **24**, 3013.—$PhCH(CHPhNO_2)CH_2COC_6H_4OMe$ (K. and Allen, *C. A.* **22**, 1333) on bromination in hot $CHCl_3$ gives a mixt. of *α-anisoyl-α-bromo-β,γ-diphenyl-γ-nitropropane* (I), m. 165°; elimination of HBr by C_5H_5N in boiling EtOH gives 92% of *3,4-diphenyl-5-anisoylisoxazoline oxide* (II), m. 158°; II does not reduce $KMnO_4$ in Me_2CO and is not affected by $Na_2Cr_2O_7$ in boiling AcOH; it liberates I from KI in AcOH and liberates Cl and NOCl when heated with PCl_5. Rearrangement of II by heating for 1 hr. with AcOK in MeOH-AcOH or by shaking I with a mixt. of MeOH, H_2O, NaOH and Et_2O until soln. results and acidifying with AcOH gives *3,4-diphenyl-5-hydroxy-5-anisoylisoxazoline* (III), m. 177°; Na_2O_2 oxidizes it to anisic acid and diphenylisoxazolone; *benzoate*, m. 173°. *α-Anisyl-γ,δ-diphenylbutanetrione oxime* (IV), m. 110° (decompn.), results by the action of alkali on II or III or directly from I if the reaction mixt. is acidified with cold HCl; the yellow IV crystallizes with 1 mol. Et_2O; boiling IV in MeOH with AcOK and AcOH gives III; a drop of HCl added to the $CHCl_3$ soln. gives *2-anisal-3-keto-4,5-diphenylpyrrolenine oxide*, purple, m. 182° (decompn.). The final degradation product of the action of weak bases or dil. alkalies on the above compds. is *3,4-diphenyl-5-anisoylisoazole* (V), m. 156°. With Zn and AcOH II and III give very sparingly sol. substances which are evidently condensation as well as reduction products; V readily combines with 2 atoms of H, giving the carbinol $C_{22}H_{19}O_3N$, m. 146°; oxidation with $Na_2Cr_2O_7$ in AcOH gives V. Hydrogenation with H and Pd of III and IV gives only complex products. Catalytic reduction of II gives a mixt. of 55% VI, 20% of VII, 5% of VIII and 20% of an oil, composed largely of secondary product. *3,4-Diphenyl-5-(α-hydroxy-4-methoxybenzyl)-isoxazoline oxide* (VI), m. 170°, which seps. first from the MeOH soln.; it liberates I from KI and Cl from PCl_5; oxidation with $Na_2Cr_2O_7$ in AcOH gives II; cleavage of VI with KOH in MeOH gives *p*-$MeOC_6H_4CHO$ and *diphenylisoxazole* (IX), m. 91°. The filtrate from VI gives a mixt. of prisms and needles, which were sepd. by hand. The prisms are a *stereoisomer* (VII) of VI, m. 160°, which shows the same behavior as VI. The needles (X) are $PhCH(CHPhNO_2)CH_2COC_6H_4OMe$. Catalytic reduction of VI gives *α,β-diphenyl-γ,δ-dihydroxy-δ-anisylbutylamine*, m. 208°. These results show quite conclusively that the H combines far more rapidly with the CO group than it does with any part of the system C:NO. The structure of IX was established by the action of O_3, the product being hydrolyzed to β-benzil monoxime. Alk. cleavage of IX gives $PhCH_2CO_2H$ and PhCN.

Rotenone. IX. Alkali fusion of some derivatives of rotenone. H. L. HALLER AND F. B. LAFORGE. *J. Am. Chem. Soc.* **52**, 4505–9(1930); cf. *C. A.* **24**, 5038.—Derritol (I), isoderritol, rotenol, dihydroxyrotenonic acid and isodihydroxyrotenonic acid on alkali fusion yield isotubaic acid (II); dihydroderritol Me ether yields dihydrotubaic acid (III); rotenonic acid, as well as several other derivs. of rotenone in which the lactone group is opened by catalytic reduction, did not give II or III on fusion with alkali. Compds. which give II or III contain the lactone group or this group has been opened by hydrolysis. The conclusion is drawn that the HO group resulting from the opening of the lactone ring is necessary for the formation of II or III. The fact that rotenol gives II contradicts the theory that cleavage of the mol. takes place at the ketone group. The nucleus of II does not exist in I as such, but is a secondary decompn. product; perhaps it does not exist in rotenone. **X. Cleavage of derritol and rotenol.** L. E. SMITH AND F. B. LAFORGE. *Ibid* 4595–8.—Methylderritolic acid with $KOH-H_2O_2$ gives a *trimethoxyphenylacetic acid*, m. 93°; this may be the 2,3,5- or 2,3,6-deriv. Oxidation with alk. $KMnO_4$ gives the next lower homolog, a *trimethoxybenzoic acid*, m. 78–80°; *amide*, m. 173°. Dihydrorotenolic acid with $KOH-H_2O_2$ gives the *acid*, $C_{12}H_{14}O_5$, crystg. with 1 mol. H_2O, m. 91–2°, contg. the 2 MeO groups of rotenol; this is named *netoric acid;* it gives no test for a phenol and does not reduce Fehling soln.
C. J. WEST

Stereochemistry of phenylpyridine compounds: The preparation and investigation of 2-(2-carboxy-6-chlorophenyl)pyridine-3-carboxylic acid and 3-(2-carboxyphenyl)-6-phenylpyridine-2,4-dicarboxylic acid. X. CATHERINE CASSELS STEELE AND ROGER ADAMS. *J. Am. Chem. Soc.* **52**, 4528–35(1930); cf. *C. A.* **24**, 5738.—The possibilities of optical isomerism in the phenylpyridines as compared with the diphenyl series is discussed. $8-ClC_{16}H_6NH_2$ by the Skraup synthesis gives 20% of *10-chloro-α-naphthoquinoline* (I), bright yellow, m. 81.5–2°; oxidation of 10 g. I with neutral $KMnO_4$ at 100° gives 5 g. of *2-(2-carboxy-6-chlorophenyl)pyridine-3-carboxylic acid*, m. 252–6°

(decompn.); the following salts were prepd.: *distrychnine*, m. 171–3°, $[\alpha]_D$ —21.37°; *dibrucine*, m. 168–70°; *dimorphine*, m. 200–4°, $[\alpha]_D$ —69.06°; *monocinchonine*, m. 154–6°, $[\alpha]_D$ 75.2°; *dicinchoninine*, m. 194–6°, $[\alpha]_D$ 117.8°; *monoquinine*, m. 152–5°, $[\alpha]_D$ —58.89. Various fractions showed no sign of resolution. α-Phenyl-β-naphthoquinoline-γ-carboxylic acid, m. 290°, on oxidation with $KMnO_4$, gives 74% of *3-(2-carboxyphenyl)-6-phenylpyridine-2,4-dicarboxylic acid* (II), m. 202°; *monostrychnine salt*, did not crystallize readily; *distrychnine salt*, m. 238° (decompn.), $[\alpha]_D$ —8.57°; *dibrucine salt*, m. 225°; *monocinchonine salt*, m. 174–6°, and then with further decompn. at 200–4°, $[\alpha]_D$ 75.26°; these salts appear to exist in only 1 form. II yields a *trichloride*, m. 127–30°; the tri-Bu ester could not be crystd.; the *trimenthyl ester*, which could not be crystd., showed $[\alpha]_D$ —38°.

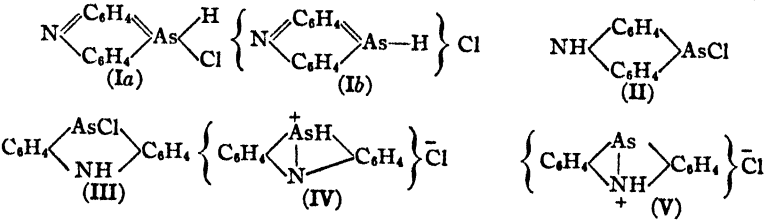
C. J. West

Synthesis of isoindenoquinolines. I. George R. Clemo and Herbert J. Johnson. *J. Chem. Soc.* 1930, 2133–8.—The present interest in quinoline derivs., particularly as antimalarials, together with the fact that 4-keto-1,2,3,4-tetrahydroquinoline (I) has a local anesthetic action, made it of interest to attempt to convert the latter into isoindenoquinolines (II) with a view of testing the physiol. action. Boiling 5 g. of I with Ac_2O in Et_2O for 18 hrs. gives 5.6 g. of the *1-Ac deriv.* (III), m. 94°. I (5.8 g.) and 6.8 g. of $3,4\text{-}(MeO)_2C_6H_3CHO$ condense in EtOH-NaOH to give 10 g. *4-hydroxy-3-homoveratrylquinoline* (IV), m. 225°; H_2SO_4 gives a faint purple color; bromination in AcOH gives the *6'-bromoveratryl deriv.*, m. 233°. IV (0.5 g.) and 2 cc. concd. H_2SO_4, allowed to stand overnight, give 0.7 g. of the *6'-sulfonic acid*, m. 308° (decompn.); ring closure does not take place. IV (8 g.) in 24 cc. $POCl_3$, heated at 100° for 12 hrs., gives 7.3 g. of the *4-Cl deriv.*, m. 96°; the *methiodide*, orange, m. 208° (decompn.); Br in $CHCl_3$ gives the *6'-Br deriv.*, m. 112°, while in AcOH there results a mixt. of the Br deriv. and the *di-Br deriv.*, light yellow, m. 220° (decompn.); attempted efforts to close the ring failed. I and $3,4\text{-}(MeO)_2C_6H_3CHO$ in AcOH, satd. with dry HCl, give *4-keto-3-veratrylidene-1,2,3,4-tetrahydroquinoline* (V), light red, m. 177–8°; concd. H_2SO_4 gives an intensely magenta soln.; EtOH-NaOH gives IV. III and $3,4\text{-}(MeO)_2C_6H_3CHO$, condensed in AcOH with HCl, give the *1-Ac deriv.* of V, bright yellow, m. 164°; catalytic reduction with Pd charcoal in AcOH gives *4-keto-1-acetyl-3-homoveratryl-1,2,3,4-tetrahydroquinoline*, m. 89°; concd. H_2SO_4 gives an intense reddish brown soln.; the *oxime* m. 208°; heating in 80% H_2SO_4 for 30 min. on the H_2O bath gives a mixt. of 2 forms of *12,13-dimethoxyisoindenoquinoline* (II), very faintly yellow prisms from MeOH, m. 193–4°, and brownish red prisms, in addn. to the yellow form, from C_6H_6, m. 193–4°; both forms give a violet fluorescence in C_6H_6 or Et_2O, while in com. abs. EtOH the fluorescence is intense green, changed to violet on the addn. of a trace of K_2CO_3; concd. HNO_3 gives a non-fluorescent deep yellow soln.; H_2SO_4 and HCl give yellow solns. with intense green fluorescence.

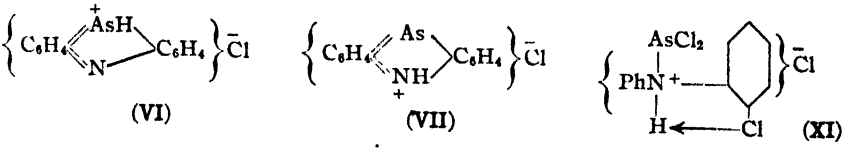
(II)

C. J. West

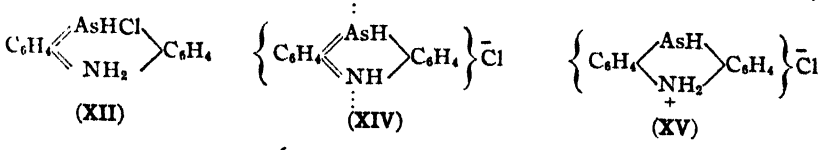
Friedel and Crafts reaction with 8-hydroxyquinoline. Konomu Matsumura. *J. Am. Chem. Soc.* 52, 4433–6(1930).—8-Hydroxyquinoline (43.5 g.), 25 g. AcCl and 400 g. $PhNO_3$ with $AlCl_3$ at 70° for 12 hrs. give 45% of the *5-Ac deriv.* (I), m. 112–2.5°; $FeCl_3$ gives a green color; *HCl salt*, yellow, m. 284–5° (decompn.); *acid sulfate*, yellow, m. 248° (decompn.); *picrate*, yellow, m. 188–9°; *chloroplatinate*, m. 275° (decompn.); *methiodide*, yellow, m. 210° (decompn.); *oxime* (II), m. 193°. The structure of I was proved by the Beckmann rearrangement of II, which gives 5-acetamido-8-hydroxyquinoline, m. 216–7.5°. The *5-chloroacetyl deriv.* was similarly prepd. in 36% yield and m. 158–9°; $FeCl_3$ gives a green color; reduction with Fe in EtOH-HCl gives I; *HCl salt*, yellow, m. 287° (decompn.); *acid sulfate*, yellow, m. 263° (decompn.); *picrate*, yellow, m. 179°; *chloroplatinate*, yellow, m. 275° (decompn.). The *5-Bz deriv.*, m. 118–9°, results in 77% yield; *HCl salt*, yellow, m. 252–60°; *acid sulfate*, yellow, m. 219–20°; *picrate*, yellow, m. 143–5°; *methiodide*, garnet-colored, m. 199.5° (decompn.); *oxime*, m. 147–8°; the Beckmann rearrangement gives the known 5-BzNH deriv., m. 237–8°. 8-Benzoyloxyquinoline, in 90% yield from BzCl in the cold; *HCl salt*, yellow, m. 124°; no condensation product was obtained with $AlCl_3$.



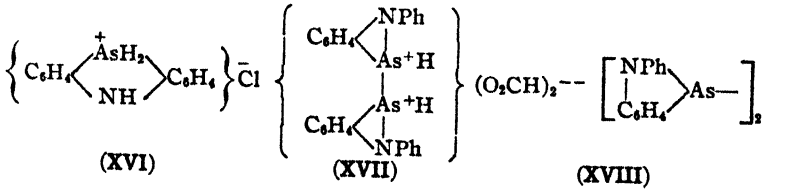
C. J. West



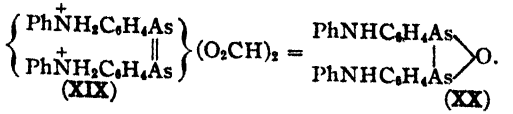
α-Chlorophenazine. FRITZ WREDE AND OSKAR MÜHLROTH. *Ber.* **63B**, 1931–5 (1930).—The surprising ease with which pyocyanine can be synthesized from α-hydroxyphenazine (*C. A.* **24**, 121) made it desirable to study the reaction with other α-substituted phenazines, which hitherto have hardly been available. The intention was to prep. an α-halogen deriv. in which the halogen was afterward to be replaced by other elements and groups. Various attempts to prep. the *α-chlorophenazine* (I) directly by the usual methods failed, nor could it be obtained from the HO compd. with P halides under the most varied conditions. It was finally obtained by a method analogous to that used in synthesizing the MeO compd., *viz.*, by coupling 3-chloro-*o*-quinone (II) with *o*-$C_6H_4(NH_2)_2$. The proposed replacement of the Cl by other substituents met with but little success. The I did not react in the slightest with alkali bromides and iodides or with NH_3 (in H_2O or alc. or in pure liquefied form); with $NaNH_2$ in boiling xylene it gave phenazine but none of the NH_2 deriv.; only with alc. K_2S or KSH at 160° did it give almost Cl-free, S-contg. products which, however, could not be obtained in pure cryst. form and gave no definite products on reduction. 2,3-$(HO)_2C_6H_3Cl$, m. 47°, was obtained in 16 g. yield from 250 g. *o*-$C_6H_4(OH)_2$ slowly treated in dry Et_2O below 5° with 310 g. SO_2Cl_2, and was oxidized to II with Ag_2O in Et_2O. The I (about 3 g. from 6 g. $(HO)_2C_6H_3Cl$), S-yellow, m. 122–3°, mol. wt. in camphor 204.5–219.6, is very slightly basic, dissolves in concd. H_2SO_4 with blood-red color changed to yellow by H_2O, in concd. HCl with orange-yellow color with sepn. of I when dild., is quite stable toward acids and alkalies, is hardly attacked by HNO_3, volatilizes without decompn. under 10 mm. and sublimes with slight decompn. under atm. pressure, is somewhat volatile with steam. *Chloroaurate*, yellow-red, m. about 232° (decompn.); *chloroplatinate*, red-yellow, does not m. 295°; *perchlorate*, golden yellow. C. A. R.



The constitution and properties of 10-chloro-5,10-dihydrophenarsazine and some derivatives. CHARLES S. GIBSON, JOHN D. A. JOHNSON AND (the late) DUDLEY C. VINING. *Rec. trav. chim.* **49**, 1006–35(1930).—Recently Kappelmeier (*C. A.* **24**, 2438) has expressed the view that the constitution of 10-chloro-5,10-dihydrophenarsazine is more adequately expressed by formula I (a or b) than by II (cf. Gibson and Johnson, *C. A.* **23**, 4473). The 1st formal proof that the substance possesses formula II was given by Gibson and Burton (*C. A.* **20**, 1606), who also showed that the original method of prepn. of these phenarsazine derivs. was strictly limited and could not be applied even to the nitro and carboxy compds. (cf. Burton and Gibson, *C. A.* **21**, 1252; Gibson and Johnson, *C. A.* **22**, 400). As to the existence of the *N*-Me deriv. which Wieland and Rheinheimer (*C. A.* **15**, 2633) claimed to have obtained in small quantity by the condensation of Ph_2NMe with $AsCl_3$, Gibson and co-workers were only able to isolate from this reaction a small quantity of 10-chloro-5,10-dihydrophenarsazine (*C. A.* **20**, 1606; **23**, 3446, 4704), while the desired synthesis was also unsuccessful as was also the methylation of the parent compd. The present authors have already shown (*C. A.* **23**, 4473) that the constitution of 10-chloro-5,10-dihydrophenarsazine may be represented by the formulas III, IV, V, VI or VII, the compd. being probably best represented by IV or V, which might be in equil., although no definite proof can be advanced in favor of the trans-annular bond formulas as against the *o*-quinonoid formula. Whereas all tervalent As derivs. in this series are colored except the *N*-acyl derivs., the quinquevalent As derivs. are colorless, unless a chromophoric group is present. Having adopted the trans-annular bond for 10-chloro-5,10-dihydrophenarsazine, it seems clear that the color of this substance must be assocd. with the presence of this bond, since those derivs. in which the presence of this bond is precluded, such as the *N*-acyl derivs., are colorless. It is therefore necessary that 2 types of derivs. be assumed, those without the trans-annular bond (the "true dihydrophenarsazines" according to Kappelmeier, *l. c.*) and those with the trans-annular bond, which are salts. The structure III may be preserved by acetylation of the H atom of the NH group or this H atom may be bound to the N by its forming part of a chelate ring, provided a suitable group is present, as, *e. g.*, the NO_2 in the 4-position. If 10-chloro-5,10-dihydrophenarsazine does not contain the NH group, it must be capable of reacting in this form since the *N*-acyl derivs. are so readily formed by the usual reactions. From the formulas IV and V and from the formulas VI and VII the former are to be preferred since As displays a remarkable tendency to pass into the "onium" condition; then the 10-Cl compd. must have a formula which allows of the free migration of the H atom from N ⟷ As. If the N and As are intimately connected this wandering will be facilitated and this is an important reason for the adoption of the trans-annular bond formula. On prepg. 10-chloro-5,10-dihydrophenarsazines from substituted diphenylamines and $AsCl_3$, the formation of an addn. compd. is often observed (change of color and evolution



of heat on simple mixing). It was now found that the following compds. condense: Ph_2NH, *o-*, *m-* and *p*-MeC_6H_4NHPh, 2,4′-, 2,3′-, and 4,4′-$MeC_6H_4NHC_6H_4Me$, *α-* and *β*-$C_{10}H_7NHPh$, $(\alpha\text{-}C_{10}H_7)_2NH$, $(\beta\text{-}C_{10}H_7)_2NH$, *p*-tolyl-*α-* and *β*-naphthylamine, *m-* and *p*-$H_2NC_6H_4NHPh$, *m-* and *p*-ClC_6H_4NHPh, 4,4′-, 3,4- and 3,5-dichlorodiphenylamine, $(p\text{-}PhNHC_6H_4)_2$, $(p\text{-}4\text{-}MeC_6H_4NHC_6H_4)_2$, *m-* and *p*-$C_6H_4(NHPh)_2$, and $(p\text{-}HOC_6H_4)_2NH$. No condensation was obtained with: Ph_2NMe, *o*-$H_2NC_6H_4NHPh$, *o-*, *m-* and *p*-$O_2NC_6H_4NHPh$, 4,4′-, and 2,4-diaminodiphenylamine, $(p\text{-}O_2NC_6H_4)_2NH$, *o*-$ClC_6H_4NHPh$, 2,4- and 2,5-$Cl_2C_6H_3NHPh$, $(2,4\text{-}Cl_2C_6H_3)_2NH$, $(2,4\text{-}Br_2C_6H_3)_2NH$, Ph_2NAc, $HCONPh_2$, Ph_2NBz, *o*-$C_6H_4(NHPh)_2$ and dicyclohexylamine. The halo-diphenylamines fall into 2 classes, those with at least 1 halogen atom in the *o*-position to the NH group, which do not condense, and those which have not and which do condense with $AsCl_3$. Nitro derivs. as a rule do not condense and the compds. which do react all possess alkyl or phenylene substituting groups; the absence of a reaction is sometimes to be ascribed to steric hindrance. As a working hypothesis for the mechanism of the condensation the scheme $\{Ph_2\overset{+}{N}H(AsCl_2)\}\bar{C}l$ (VIII) ⟶ Ph_2NAsCl_2 (IX) ⟶ IV is accepted, a N-As bond being formed in the first stage of the reaction. A nitro group, in virtue of its strongly negative character, would prevent the formation of the primary compd. and a *N*-acyl group would act similarly. The absence of a condensation reaction when at least one Cl atom is present in the *o*-position to the NH group is ascribed to the formation of a chelate ring (XI). The red color of the soln., obtained by Wieland and Rheinheimer (*l. c.*) by the reduction of 10-chloro-5,10-dihydrophenarsazine with Zn in AcOH disappeared on further reduction and reappeared on addn. of the starting product; it was therefore suggested that the completely reduced soln. contains the compd. XII, while the colored soln. contains the quinhydrone substance XIII (= III + XII). Razuvaev, however, considers these colored compds. to be of the meriquinonoid type XIV (*C. A.* **23**, 3708, 4474; **24**, 1114, 2132). The existence of such a compd. having an odd no. of valency electrons in the mol. must for the present be considered doubtful. Neither is the formula XII in accordance with modern views on quinquevalent N and it is suggested that the formula of the completely reduced substance should be represented by XV or XVI, the absence of color being due to the absence of the trans-annular bond. In an attempt to isolate the deeply colored reduction product of 10,10′-oxybis(5,10-dihydrophenarsazine) a soln. of this compd. in HCO_2H was allowed to stand for several days in a closed flask. Amorphous material first sepd. and, later, dark reddish brown prisms (substance A) in moderate yield, m. 320°. This substance dissolves in *cold* HCO_2H with a crimson color and, on warming with AcOH, yields 10-aceto-5,10-dihydrophenarsazine. On heating A in air it loses HCO_2H with the formation of a yellow residue (substance B) which has the same compn. as 10,10′-bis(5,10-dihydrophenarsazine) and which reacts with Br to give 10-bromo-5,10-dihydrophenarsazine. On hydrolysis substance A gives 2 different oxy-compounds, depending on the conditions of the hydrolysis. On boiling with a mixt. of EtOH and concd. NH_4OH is obtained cream-colored 10,10′-oxybis-(5,10-dihydrophenarsazine), which dissolves in cold HCO_2H with an orange color, becoming crimson on warming, while on shaking with acetone and NH_3 for 30 min. a lemon-yellow oxide is pptd. which dissolves in cold HCO_2H with the immediate production of a crimson color. In the former case aerial oxidation would appear to have taken place, while in the latter case a new oxy compd., $C_{24}H_{20}ON_2As_2$, is formed which is converted into the ordinary oxy compd. by boiling in alc. in an open vessel, oxidation taking place. On allowing substance B in HCO_2H to stand for several days, the crimson color gradually fades and a brilliant scarlet compd. (C) gradually seps., which, on treatment with hot alc.-NH_3 is converted into ordinary 10,10′-oxybis(5,10-dihydrophenarsazine). In view of the fact that on boiling of the HCO_2H soln. the latter substance is completely reduced to $HCONPh_2$ and As_2O_3 (Razuvaev, *l. c.*) it would appear that the As-C linking is not very strong and in connection with this fact the formulas XVII, XVII and XIX are suggested for the substances A, B and C and formula XX for the new oxy deriv. The color of partly reduced solns. of dihydrophenarsazine is explained by assuming the presence of substance A or of its ion. *2,4-Dinitrodiphenylamine-6′-arsonic acid*, m. 223–50, was pred. on boiling 2,4-$(O_2N)_2C_6H_3Br$, *o*-$H_2NC_6H_4AsO_3H_2$, K_2CO_3 and a trace of Cu powder in AmOH during 5 hrs. On treating this acid in a boiling mixt. of EtOH, concd. HCl and a trace of I with SO_2, it is converted into *2,4-dinitrodiphenylamine-6′-dichloroarsine*, m. 151–2°. In the same way *4-hydroxydiphenylamine-6′-arsonic acid*, m. 197–8° (vigorous decompn.), was prepd. from *p*-BrC_6H_4OH and *o*-$H_2NC_6H_4AsO_3H_2$. The methods given in the literature for the prepn. of 2,4-$(H_2N)_2C_6H_3NHPh$ giving unsatisfactory results, this compd. was prepared by



reduction of 2,4-$(O_2N)_2C_6H_3NHPh$ with Fe fillings and AcOH in 50% EtOH. *m-Bromophenylarsonic acid*, prepd. by the Bart reaction from *m*-$BrC_6H_4NH_2$, m. 180–1°; for details the original paper is to be consulted. This acid was converted into *m-bromophenyldichloroarsine*, b_{18} 165°, on treating in hot concd. HCl, contg. a trace of HI, with SO_2. Attempts to condense Ph_2AsCl with MeEt malonate were unsuccessful, Ph_2AsO_2H being obtained. On refluxing Ph_2AsO_2H in $SOCl_2$ for 4 hrs., the acid is transformed into *diphenylarsine trichloride;* for the same reaction with $PhAsO_3H_2$ the $SOCl_2$ is to be purified by distn. over white beeswax and to be dild. with benzene, the reaction being too vigorous without diln. With the precautions mentioned in the original paper, $HCl.NH(C_6H_4)_2AsCl_3$, m. 105–6° in a sealed tube, is obtained. The action of HCl on 10-chloro-5,10-dihydrophenarsazine at high temps. gives appreciable quantities of $AsCl_3$ and Ph_2NH. On refluxing a benzene suspension of 10,10′-thiobis(5,10-dihydrophenarsazine) with $Hg(CN)_2$ for 6 hrs., this compd. is transformed into *10-cyano-5,10-dihydrophenarsazine*, m. 223–4°. The action of HF on

the 10-Ac compd. in AcOH gave a yellow microcryst. material, contg. AcOH of crystn. and having the compn. $[NH(C_6H_4)_2AsF]_2.AcOH$, m. 285–7°; in the same way *10-aceto-5,10-dihydrophenarsazine picrate*, m. 170–4°, was prepd. On *rapidly* cooling a satd. soln. of 10-iodo-5,10-dihydrophenarsazine in benzene, a mol. compd. with benzene seps. in highly colored red scales with a green reflex. *10-Thiocyano-5,10-dihydrophenarsazine*, m. 238–40°, may be obtained from the Cl compd. and KCNS; from low-boiling solvents it usually crystallizes in yellow needles and from high-boiling solvents as a mixt. of yellow and red needles, while from *o*-$C_6H_4Cl_2$ and CCl_4 only red needles are obtained. All these different prepns. melt at the same temp. The Cl compd. reacts with Ag_2SO_4 in EtOH to give *10,10′-sulfato-bis(5,10-dihydrophenarsazine)*, which, however, could not be sepd. from the AgCl formed simultaneously; on the other hand the 10-Ac compd. is converted into 2 sulfates on treatment in boiling AcOH soln. with

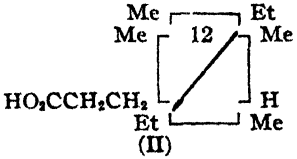
concd. H_2SO_4. The bright red sulfato deriv. seps. from the boiling soln. while the more sol. yellow compd. is obtained on cooling. There may be a fundamental difference between these 2 forms since the red compd. gives an intense crimson color on warming with HCO_2H while the yellow form gives no color with this reagent. When 10,10′-oxybis(5,10-dihydrophenarsazine) in C_6H_6 is treated with Cl_3CCO_2H, *10-trichloroaceto-5,10-dihydrophenarsazine*, m. 159–60°, is obtained in pale green plates. From the 10-Ac compd. and anhyd. $(CO_2H)_2$ in AcOH, *10,10′-oxalatobis(5,10-dihydrophenarsazine)* was prepd., m. 295–300°. *10-Formo-5,10-dihydrophenarsazine*, m. 315–20°, is obtained from the 10,10′-oxy compd. and boiling HCO_2H; on heating this compd. in air at 110° for some time, the oxide **XX** is formed. The expts. on the substances A, B and C, already described briefly, are described in detail, for which reference is made to the original paper. On boiling the solution of 10,10′-oxybis(5,10-dihydrophenarsazine) for 10 min., *10,10′-bis(5,10-dihydrophenarsazine)* is formed by reduction. *Phenyl-α-pyridylamine* could not be prepd. according to Chichibabin (*J. Russ. Phys.-Chem. Soc.* 50, 497(1920)) from α-aminopyridine and PhBr, but with PhI the reaction proceeds readily. The product, however, shows an indefinite m. p. and it is therefore suggested that the phenylation of α-aminopyridine leads to phenyl-α-pyridylamine as well as to *N*-phenyl-α-pyridoneimide. While phenyl-α-pyridylamine does not condense with $AsCl_3$ in o-$C_6H_4Cl_2$, di-α-pyridylamine, when treated in the same way, gives a small yield of a microcryst. powder, which does not belong to the dihydrophenarsazine type and which was not investigated further. The reaction between $PhAsCl_2$, $AlCl_3$ and $ClCH_2COCl$ in CS_2 only gives $PhCOCH_2Cl$, de-arsenication having taken place.

C. F. VAN DUIN

Strychnine alkaloids. V. Degradation experiments with dihydrobrucine. HEINRICH WIELAND AND WALTER GUMLICH. *Ann.* 482, 50–5(1930); cf. *C. A.* 24, 4046.—Dihydrobrucine, warmed with 1:1 HNO_3 at 50° for 0.25 hr., gives *dihydrocacotheline nitrate*, $C_{21}H_{23}O_7N_3 \cdot HNO_3$, yellow-red, in almost quant. yield; Br in HBr on the H_2O bath gives the *dihydro acid*, $C_{19}H_{24}O_6N_2$, whose *IIBr salt* is obtained in 30% yield; the free acid shows $[\alpha]_D^{23}$ —2.9° (1.04% aq. soln.); catalytic reduction gives quant. the *tetrahydro acid*, $C_{19}H_{26}O_6N_2$, $[\alpha]_D^{23}$ 17.7° (2.09% aq. soln.). *Dihydrobrucine methiodide*, crystg. with 1 mol. H_2O, m. 290° (decompn.), results by the use of MeI or of Me_2SO_4 followed by KI; the free base forms a strongly alk. aq. soln., from which the base seps. as pale yellow scales; heating at 176° causes a marked change in the base but no volatile base is formed. Heating dihydrobrucine with MeONa for about 20 min. gives 30–5% of the *hydrate*, $C_{23}H_{30}N_2O_5$, pale yellow, m. 240° (decompn.), $[\alpha]_D^{28}$ —183.7° (0.1117 g. in 4.2317 g. $CHCl_3$), contg. 1.3 atoms active H; *methiodide*, bright yellow, does not m. 290°; Ag_2O gives a strong base, decompg. about 240°; the *HCl salt* appears to crystallize with 1 mol. H_2O.

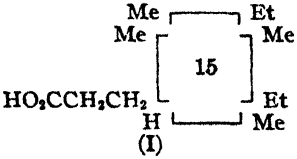
C. J. WEST

Chellol glucoside. PAUL FANTL AND SALEM IBRAHIM SALEM. *Biochem. Z.* 226, 166–79(1930).—The alc. extn. of the seeds of the umbelliferous plant *Ammi visnaga* yields about 3 g. per kg. of a substance which m. sharply 175° and has been identified as a glucoside that on acid hydrolysis gives $C_6H_{12}O_6$ and $C_{13}H_{10}O_6$. It gives a single mono-Ac compd. and still contains the lactone O, judged by the yellow color it develops with concd. HCl. On hydrolysis with alkali it yields a compd. $C_{11}H_{10}O_4$, which is in combination with an acid identical with Fischer's *d*-glucosidoglycolic acid. The former product of the alk. hydrolysis contains a MeO group, is sol. in strong alkali from which it can be pptd. by acid, even CO_2. It gives an intense green color with $FeCl_3$ which indicates the probable presence of a phenolic OH group. It also contains one C:O group which can be demonstrated with NH_2OH. Three structural formulas are suggested for the glucoside, and their merits are discussed.



S. MORGULIS

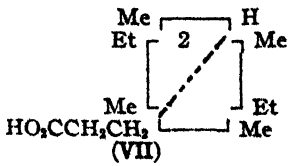
Picrocrocin, the bitter principle of safran. H. E. W. LUTZ. *Biochem. Z.* 226, 97–128 (1930).—In acid hydrolysis of picrocrocin no CO_2 is formed in appreciable amts., but HCHO has been identified. The mol. wt. of the picrocrocin is 324.2, and the formula for its semicarbazone $C_{11}H_{17}ON_3$, m. 172.6°, has been corroborated. The safran camphor $C_{10}H_{14}O$ can be hydrogenated in the presence of Pt oxide to an odorless deriv. $C_{10}H_{16}O$, thus showing that it contains a double bond. From considerations of mol. wt. detns. on picrocrocin it seems probable that the glucoside contains only a single mol. of *d*-glucose. From the data of the elementary analysis, mol. wt. detns. and of the hydrolysis of the picrocrocin which yields a mol. of camphor $C_{10}H_{14}O$, a mol. of *d*-glucose, and HCHO it is suggested that the formula $C_{17}H_{28}O_8$ best fits the known facts.



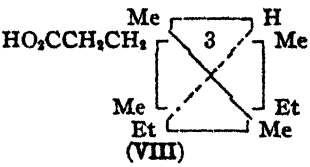
S. MORGULIS

Syntheses of porphyrins. XXXI. Syntheses of further pyrroporphyrins. H. FISCHER AND HERBERT BERG. *Ann.* 482, 189–213(1930); cf. *C. A.* 24, 5762.—Al

though the pyrroporphyrin obtained from the degradation of cellulose, transformed into the monopropionic acid, has been shown by synthesis to be pyrroporphyrin 15 (I) (cf. table in *Ann.* **473**, 213), it seemed of interest to synthesize the isomeric *pyrroporphyrin 12* (II). 2-Carboxy-3-methyl-4-bromo-5-formylpyrrole (2.1 g.) and 1 g. cryptopyrrole, stirred with 1 cc. AcOH and the solid mass treated with 2 cc. 48% HBr, give 3 g. of *4,3',5'-trimethyl-4'-ethyl-3-bromo-5-carboxypyrromethene-HBr*, orange, decomps. above 130°; the free base is easily decompd.; Br in HCO_2H in the cold gives *4,3',5'-trimethyl-4'-ethyl-3,5-dibromopyrromethene-HBr* (III), steel-blue from AcOH, Cu-colored needles from Me_2CO, decomps. 175°. III (5.5 g.) and 4.5 g. 3,5,3'-trimethyl-4-ethyl-4'-propionic acid-5'-bromopyrromethene-HBr, intimately mixed and added to 20 g. pyrotartaric acid at 130°, then heated gradually to 150° during 1.25–1.5 hrs. give II and the *Br deriv.* (IV), sepd. by fractional extn. from EtOH by 2.5% HCl (II) and 10% HCl (IV); the yield is about 10%.

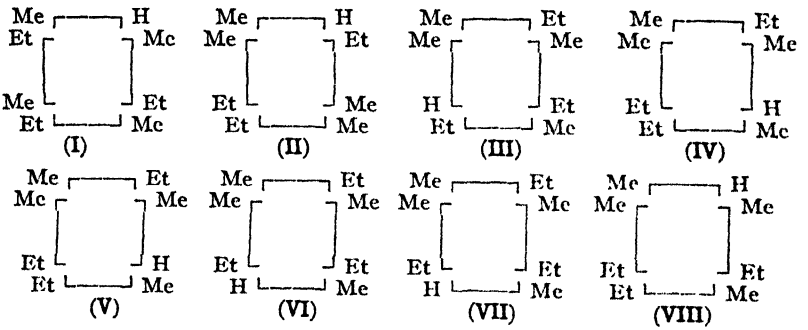


(II)



(I)

II has an acid no. of 1.3. Excess AcOH-$Fe(OAc)_2$, followed by NaCl, gives *pyrrohemin 12*, $C_{31}H_{32}O_2N_4FeCl$, steel blue. II with MeOH-HCl gives a *Me ester*, m. 242° (cor.); the *hemin*, $C_{32}H_{34}O_2N_4FeCl$, bluish black, m. 260° (cor.). IV has an acid no. of 7.5. The spectra of II and IV are identical with those of the corresponding derivs. of I. *Cu salt*, $C_{31}H_{31}O_2N_4BrCu$, red needles; *Me ester*, m. 304° (cor.), acid no. 9 (*Cu salt*, red needles, m. 259° (cor.)). 4,3',5'-Trimethyl-3-ethyl-4'-bromo-5-carboxypyrromethene-HBr with Br in HCO_2H gives *4,3',5"-trimethyl-3-ethyl-5,4'-dibromopyrromethene-HBr* (V), green leaflets, blackens at 215°. 2-Carboxy-3-methyl-4-ethyl-5-formylpyrrole and cryptopyrrolecarboxylic acid in a little EtOH, treated with 48% HBr, give *3-ethyl-4,3',5'-trimethyl-5-carboxy-4'-propionic acid-pyrromethene-HBr*, yellowish red, decomps. 170°; warming in AcOH-Br at 70° gives *3-ethyl-4,3',5'-trimethyl-5-bromo-4'-propionic acid-pyrromethene-HBr* (VI), cinnabar-red, decomps. 216°. Heating a mixt. of V and VI with pyrotartaric acid at 130° gives 10% of pyrroporphyrin 2 (VII), acid no. 1.3; the *hemin*, $C_{31}H_{32}O_2N_4FeCl$, forms dark blue tablets; *Me ester* of VII, m. 229° (cor.); its *hemin*, black-blue, m. 265°. The *bromopyrroporphyrin 2*, which is also formed, crystallizes in red rods; its acid no. is 7.5; *Cu salt*, red needles; *Me ester*, m. 291° (*Cu salt*, red, m. 235° (cor.)). 4,3',5'-Trimethyl-3-ethyl-5-bromo-4'-propionic acid-pyrromethene-HBr and III give a mixt. of *pyrroporphyrin 3* (VIII) and the *Br deriv.* (IX). VIII gives a *Me ester*, m. 219° (cor.). The corresponding *hemin* crystallizes in black-blue rods; its *Me ester*, black-blue, m. 274° (cor.). IX yields a *Cu salt*, red needles; *Me ester* m. 254° (cor.) (*Cu salt*, red, m. 230° (cor.)).



(VII)

(VIII)

2-Carboxy-3-methyl-4-propionic acid-5-formylpyrrole and 2,4-dimethylpyrrole with AcOH and HBr give *4,3'5'-trimethyl-3-propionic acid-5-carboxypyrromethene-HBr*, red, m. 168°; with 3,4'-diethyl-4,3'-dimethyl-5-bromo-5'-bromomethylpyrromethene-HBr there results VIII. The HCl mother liquors from the synthesis of II and VIII are neutralized with NaOH, extd. with Et_2O, washed with H_2O and 10% NaOH and shaken with 5% HCl, which removes *deuteroetioporphyrin* II (X), acid no. 1.75, while 10% HCl exts. the *Br deriv.*, red, acid no. 8 (*Cu salt*, red needles); X forms a *hemin*, bluish black. Heating VI at 130° with pyrotartaric acid and raising the temp. to 170° during 15 min. gives 15% of mesoporphyrin II (XI), whose Me ester m. 228°. Hemopyrrolecarboxylic acid aldehyde and opsopyrrole in EtOH give *3-propionic acid-4,5,3'-trimethyl-4'-ethylpyrrolemethene-HBr*, brown, decomps. 178°; the *5'-Br deriv.*, deep red, decomps. 204°. This likewise gives XI on heating with pyrotartaric acid. 3,5,3'-Trimethyl-4-ethyl-4'-propionic acid-pyrromethene-HBr and MeOK, heated 1.5 hrs. at 180–5° in a bomb tube, give coproporphyrin I, whose Me ester m. 248°. XXXII.

Introduction of the hydroxymethyl, the methyl malonacid and the propionic acid residues into porphyrins. H. FISCHER AND HANS-JOACHIM RIEDL. *Ibid* 214–25.—Deuterohemin (2 g.) in 200 cc. $ClCH_2OMe$ and 15 cc. $SnCl_4$ (added during 5 min. to the cooled soln.), allowed to stand 10 min. at room temp. gives quant. the *FeCl deriv.* of *1,3,5,8-tetramethyl-6,7-dipropionic acid-2,4-dihydroxymethylporphin*, which, crystd. from AcOH, contains 1 Ac group; sapon. occurs during the reaction, for the test for the MeO group is negative. With AcOH-HBr at 40° the Fe is removed; the residue with MeOH at 50° gives the *ether ester* (I), $C_{36}H_{42}O_6N_4$, m. 202° (a 2nd sample m. 215°; the lower-melting form, on standing several months, m. 212°); total reduction of I with AcOH-HI and PH_4I gives 2,3,4-trimethylpyrrole. I gives an *iron salt*, m. 241°. I and AcOH-HBr in a sealed tube at room temp. for several days give *dibromomethyl-deuteroporphyrin-HBr*, very hygroscopic prisms. The Br deriv. from 0.2 g. I and 8 cc. AcOH-HBr in 90 cc. dry Me_2CO, shaken with $CHK(CO_2Et)_2$ from 2 g. acid, gives 0.25 mg. of *1,3,5,8-tetramethyl-2,4-di(methyl malonate)-6,7-dipropionic acid-porphin*, m. 202°; the *Et ester* m. 161°; the spectra of the 2 esters are identical. The *Fe salt* of the Me ester sinters 165°, m. 200°. **XXXIII. Syntheses of pyrroetioporphyrins I, II, III, IV, VI and VIII and of a dimethyldiethylporphin.** H. FISCHER AND ANTON SCHÖRMULLER. *Ibid* 232–51.—There are 8 isomeric pyrroetioporphyrins, of which V and VII have been previously synthesized (*C. A.* **23**, 5191; **24**, 4048). A mixt. of

4,3',5'-trimethyl-4'-ethyl-3-bromo-5-carboxypyrromethene-HBr and 3,4'-dimethyl-4,3'-diethyl-5-bromomethyl-5'-bromopyrromethene-HBr, heated with succinic and pyrotartaric acids 45 min. at 145–50°, the resulting product dissolved in AcOH-HCl, poured into a large vol. of Et_2O and extd. with 3.5% HCl to remove the etioporphyrin and then with 10% HCl, gives the *Br deriv.* of I; the Br is removed by dissolving in C_5H_5N and EtOH-KOH, adding Pd-$CaCO_3$ and $N_2H_4 \cdot H_2O$ and heating 45 min. on the H_2O bath; I m. 335°. The *Br deriv.* of III results from the methene of brominated hemopyrrole and the brominated methene from 2,4-dimethyl-5-formylpyrrole and opsopyrrole; the *Cu salt* forms red needles, m. 323° (decompn.); III m. 330°. 2,3-Dimethyl-5-formylpyrrole and hemopyrrole with HBr in EtOH give a good yield of *4,5,4',5'-tetramethyl-3'-ethylpyrromethene HBr* (IX), orange with green surface luster, m. 230° (decompn.); with 4,4'-dimethyl-3,3'-diethyl-5,5'-dibromopyrromethene-HBr, this yields II (1,4,5,8-tetramethyl-3,6,7-triethylporphin), m. 330–2°; *Cu salt*, scarlet-red needles, m. 263°. 3,3'-Dimethyl-4,4'-diethyl-5,5'-dibromopyrromethene-HBr and IX give IV (1,3,5,8-tetramethyl-2,6,7-triethylporphin), needles, m. 327°; *Fe salt*, black leaflets, slowly decomps. about 330°; *Cu salt*, rods, m. 333°. Pyrrole-α-aldehyde (X) and cryptopyrrole in AcOH-HBr give *3,5-dimethyl-4-ethylpyrromethene-HBr*, yellow, m. 193° (decompn.); Br in AcOH gives the *di-Br deriv.*, darkens 200°, does not m. 300°; heating with succinic and pyrotartaric acids at 190–210° for 30 min. gives *1,5-dimethyl-2,6-diethylporphin* (XI), m. 310°, acid no. 3. X and hemopyrrole give *4,5-dimethyl-3-ethylpyrromethene-HBr*, reddish yellow, m. 197°; *di-Br deriv.*, m. 145°; heating with the acid mixt. gives XI; the *hemin* forms black-violet rods (*Cu salt*, needles, m. 312°). The action of oleum on XI is discussed and the spectra of the products are given. Furfural and cryptopyrrole in Et_2O-HBr give a *methene-HBr*, green, m. 157° (decompn.). Thiophene-α-aldehyde gives the *methene-HBr*, $C_{13}H_{16}NSBr$, yellow, m. 133°, which could not be brominated. 2,4-Dicarbethoxy-3-methyl-5-formylpyrrole and $CH_2(CO_2H)_2$ in EtOH-$PhNH_2$, heated 15 hrs. on the H_2O bath give *2,4-dicarbethoxy-3-methylpyrrole-5-acrylic acid*, m. 244°; reduction with Na-Hg gives the propionic acid, m. 209°. *3,5-Dicarbethoxy-4,3',5'-trimethyl-4'-ethylpyrro-*

methene-HBr, brownish yellow, m. 160–2°; the free *base* forms reddish yellow needles, m. 107°. *2,5-Dicarbethoxy-4,3',5'-trimethyl-4'-propionic acid-pyrromethene HBr*, yellow, m. 137–8° (decompn.). C. J. WEST

Zymosterol. II. F. REINDEL AND A. WEICKMANN. *Ann.* **482**, 120–9(1930); cf. *C. A.* **24**, 624.—Crude zymosterol acetate, contg. ergosterol, is treated in Et_2O with Br and $AcOONH_4$ in AcOH, giving *zymosterol acetate dibromide* (I), m. 168–9° (cor.), $[\alpha]_{5461}$ —9.7° (*c* 1.119), which can be crystd. only from indifferent solvents. Sapon. gives the *dibromide*, m. 157–8°, $[\alpha]_{5463}$ 7.1° (*c* 0.418). The Br may be removed from I by Zn and AcOH at room temp., giving the acetate, m. 102–4°, $[\alpha]_D$ 33.6°, $[\alpha]_{5462}$ 38.9° (*c* 1.119); this is sapond. to free zymosterol (II), m. 107–10°, crystg. with 1 mol. H_2O, $[\alpha]_D$ 52.2°, $[\alpha]_{5463}$ (*c* 1.063); *benzoate*, m. 125–7°, clears at 130°, $[\alpha]_D$ 44.6°, $[\alpha]_{5463}$ 51.5° (*c* 1.001); the ultra-violet absorption curve of pure II is given. II in abs. EtOH is unchanged after being subjected to the action of ultra-violet light for 2 hrs.; a crude sample contg. ergosterol shows a marked increase in rotation after the action of the light for periods from 1 to 8 hrs. α-Dihydrozymosterol with HCl in $CHCl_3$ gives a *β isomer*, m. 99–100°, $[\alpha]_{5463}$ 32.1° (*c* 0.430), which is pptd. by digitonin; the Ac deriv. m. 74–5°; catalytic reduction gives *zymostanol*, m. 139–40°, crystallizes with 2 mols. H_2O and is pptd. by digitonin, $[\alpha]_{5463}$ 20.6° (*c* 0.241); *acetate*, m. 130–1°, crystals with 1 mol. MeOH. Oxidation of II with CrO_3-AcOH gives *zymostadienone*, m. 162–4° (cor.); *oxime*, m. 238–40° (cor.). C. J. WEST

Stigmasterol and its empirical formula. HÅKAN SANDQVIST AND J. GORTON. *Ber.* **63B**, 1935–8(1930).—On the basis of analyses of degradation products, Windaus and Brunken concluded that stigmasterol (I) has the compn. $C_{30}H_{50}O$, while S. and G.'s analyses of the I, its acetate (II) and acetate tetrabromide (III) point to the compn. $C_{29}H_{48}O$. Of the published analyses of its halogenated derivs., many agree better with the C_{30}- and some with the C_{29}-formula. The mol. wt. (432) for II in $C_{10}H_8$ found by Windaus and Hauth does not serve to establish which of the 2 formulas is correct (calcd. mol. wts. 468 and 454, resp.). Attempts to det. the mol. wt. in camphor by Rast's method gave values which varied tremenduously, the av. being about 471. The di-CO_2H acid obtained from I has the compn. $C_{30}H_{52}O_4$ (equiv. wt. 238) or $C_{29}H_{50}O_2$ (equiv. wt. 231); W. and B. by titration found 231, and S. and G. by the quant. sapon. method applied by Vesterberg and Vesterberg to betulin found for II, as the av. of 4 concordant titrations of II, an equiv. wt. of 452.3 (calcd. for $C_{31}H_{50}O_2$, 454.4). This seems to establish the C_{29}-formula for I. The III m. 202–3° (cor., decompn.), $[\alpha]_D$ —40° ($CHCl_3$, *p* 5). II m. 144.0–4.6°, $[\alpha]_D$ —55.0°. I, m. 169–70°, $[\alpha]_D^{22}$ —51.0° (*p* 4.8). C. A. R.

Synthesis of nervonic acid. J. B. HALE, W. H. LYCAN AND ROGER ADAMS. *J. Am. Chem. Soc.* **52**, 4536–9(1930).—Synthesis has shown that nervonic acid (Klenk, *C. A.* **19**, 2695; **21**, 44) is the *cis*-form of erucylacetic acid. Erucyl bromide and $CHNa(CO_2Et)_2$ give 78% of *Et erucylmalonate*, $b_{0.001}$ 203–7°; hydrolysis and heating to 175° give erucylacetic acid or nervonic acid; fractional crystn. gives the *cis*-form (I), m. 39–9.5°, and the *trans*-form (II), m. 61°. I is identical with Klenk's acid. I is transformed into II by melting over dil. HNO_3. Reduction of either I or II gives tetracosanoic acid (III), m. 83–4°. A mixt. of I and II gives an *Et ester* b_1 233–4°; reduction gives the Et ester of III, m. 55–6°. C. J. WEST

Sterols of yeast. II. HEINRICH WIELAND AND G. A. C. GOUGH. *Ann.* **482**, 36–49(1930), cf. *C. A.* **23**, 4948.—In continuing the examn. of the sterol fraction of yeast, the following new products have been isolated. *Episterol*, $C_{27}H_{44}O$, m. 135–6°, $[\alpha]_D^{20}$ 6.2° (0.0376 g. in 2 cc. $CHCl_3$), takes up 1 mol. of H_2O on standing in the air 1 month, *Bz deriv.*, m. 161–3°, $[\alpha]_D^{20}$ 11.8° (0.0436 g. in 2 cc. $CHCl_3$). *Anasterol*, m. 157–9°; $[\alpha]_D^{25}$ —8.1° (0.030 g. in 2 cc. $CHCl_3$); *benzoate*, m. 180–2°, $[\alpha]_D^{24}$ —13.8° (0.030 g. in 2 cc. $CHCl_3$). A product, m. 105° (decompn.), contg. much zymosterol, on crystn. from EtOH, transformation into the benzoate and further crystn. from Me_2CO, gives a *benzoate*, m. 158–60°, $[\alpha]_D^{27}$ —4.4° (0.1144 g. in 5 cc. $CHCl_3$), of a *sterol*, m. 144–6°, $[\alpha]_D^{25}$ —33.8° (0.0266 g. in 2 cc. $CHCl_3$). The mother liquor of this sterol gives *hyposterol*, m. 100–2°, $[\alpha]_D^{20}$ 12.5° (0.0385 g. in 2 cc. $CHCl_3$); *benzoate*, m. 119–21°, clears 138°, $[\alpha]_D^{25}$ 19.1° (0.0812 g. in 5 cc. $CHCl_3$); *p-nitrobenzoate*, m. 154–5°, clears 180°, $[\alpha]_D^{27}$ 26.7° (0.1068 g. in 5 cc. $CHCl_3$); *dihydro deriv.*, m. 123–5°, $[\alpha]_D^{21}$ 31.2° (0.0256 g. in 2 cc. $CHCl_3$). The Salkowski, Liebermann-Burchard and Tortelli-Jaffe color reactions are given by ergosterol, zymosterol, anasterol, episterol, hyposterol and the sterol, m. 144–6°. Absorption spectra are also given. C. J. WEST

Montignie's isomer of cholesterol, and the effect of heat on cholesterol. YOSHIO KAISHIO AND JOHN ADDYMAN GARDNER. *Biochem. J.* **24**, 1047–50(1930).—K. and G.

could not confirm Montignie's claim (*C. A.* **24**, that he had prepd. a new isomer of cholesterol. BENJAMIN HARROW

Degradation acid of ergosterol. FRITZ REINDEL AND KARL NIEDERLÄNDER. *Ann.* **482**, 264–79(1930).—Oxidation of 10 g. ergosterol by 150 cc. HNO_3(d. 1.4) by gently boiling about 100 hrs. gives up to 2.5 g. of an *acid*, $C_8H_8O_6$ (I), best freed from the accompanying NO_2 compds. by extn. of the cold satd. aq. soln. with 2 vols. Et_2O, cooking with charcoal and pptg. the acid with HCl or by sublimation at 0.01 mm. Hg at 150–200°, or heating with a little Ac_2O and decompg. the anhydride with 10% NaOH; I crystallizes with 1.5 mols. H_2O, m. 268°; it contains 3 atoms active H; the Na and K salts are difficultly sol. in H_2O; the acid $PhNH_2$ salt, slightly sol. in MeOH, is characteristic. The *anhydride* is formed as above and m. 268°. Attempts to split off the CO_2 groups gave the anhydride or caused total decompn. of the acid. I is stable toward all oxidizing agents but CrO_3-H_2SO_4, which completely oxidizes it. I cannot be catalytically reduced. The *acid $PhNH_2$ salt*, $C_8H_8O_6.2PhNH_2.2H_2O$, m. 300°; the *trianilide* m. over 300° and forms a *mol. complex* with $PhNH_2$, brick-red, m. above 300°. I in abs. MeOH, treated with dry HCl for about 15 min., gives the *mono-Me ester*, m. 150–2°; at 120° the ester loses 1 mol. MeOH, giving the anhydride; soln. in 10% NaOH causes sapon. If the reaction is continued for 8–10 days there results the *di-Me ester*, m. 140–3°. CH_2N_2 in Me_2CO gives the *tri-Me ester*, m. 123–4°, also obtained from the mono-Me ester and CH_2N_2; reduction gives an oily compd.; partial sapon. with MeOH-KOH gives an isomeric *Me ester*, m. 172°, which also yields an anhydride at 120°. The tri-Me ester and MeMgI give a non-cryst. carbinol, probably $C_6H_5(CMe_2OH)_3$, oxidized by CrO_3 in AcOH to the *compd.*, $C_{11}H_{12}O_3$, m. 235°, which forms a *mol. compd.* with *p*-$O_2NC_6H_4NHNH_2$, citron-yellow, m. 138–9°. In comparative expts. with 3 g. sterol and 45 cc. HNO_3 (d. 1.4), heated 30 hrs. and then concd. to 10 cc., ergosterol, its acetate and irradiated ergosterol gave 0.35, 0.3 and 0.03 g. acid while α- and β-ergostenol, ergostanol, cholesterol, zymosterol and sitosterol acetate gave no acid. From the decompn. products of the action of O_3 on ergosterol acetate there were isolated a small amt. of isocaprylaldehyde, $C_6H_{12}O$ (as the semicarbazone) and methylglutaric acid (as Ag salt). C. J. WEST

Methylation of phenols by methyl sulfate. A suggested mechanism. HERBERT H. HODGSON AND JOSEPH NIXON. *J. Chem. Soc.* 1930, 2166–8.—A comparative study of the usual method of methylation (aq. alk. soln. with Me_2SO_4) and of the method proposed by Haworth and Lapworth (reaction in $C_6H_4Me_2$ with K_2CO_3) gave the following results: PhOH 65, 0; *o*-MeC_6H_4OH 71.4, 0; *m*-isomer 82, 0; *p*-isomer 71.3, 0; *o*-$O_2NC_6H_4OH$ 47, 71.5; *m*-isomer 65, 65; *p*-isomer 55.5, 79.6; *o*-ClC_6H_4OH 72.5, 14; *m*-isomer 81, 28; *p*-isomer 81, 9; 6,2-$Cl(O_2N)C_6H_3OH$ 19.5, 75; 2,4-isomer 8, 86; 4,2-isomer 0, 75; 2,5-$Me(O_2N)C_6H_3OH$ 0, 0; 4,2-isomer 9, 73; 2,6-isomer 18, 41.5; 4,2,6-$FI_2C_6H_2OH$ 40, 9.7; 4,2,6-$FBr_2C_6H_2OH$ 53, 53; 4,2,6-$FCl_2C_6H_2OH$ 10, 60. An electronic interpretation is given to account for the differences observed in the 2 methods. C. J. WEST

Production of the methylglyoxal and pyruvic acid step of alcoholic sugar cleavage as a demonstration experiment (NEUBERG, KOBEL) **11A**. Acids of montan wax (HOLDE, *et al.*) **21**. Phosphatides (KLENK) **11A**. The sorption of H_2S by K benzenesulfonate and a thiohydrate of this salt (LANGE, LEWIN) **2**. Action of hypoiodite solution on cellulose preparations (HESS, *et al.*) **23**. Hg recovery from aqueous sludges (Brit. pat. 332,106) **18**.

Cyclic hydrocarbons by reduction of oxygenated compounds. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 331,199, Feb. 8, 1929. Compds. such as phenols, cresols, furfurol and cyclohexanol are converted into the corresponding cyclic hydrocarbons by heating under pressure with H (or a gas mixt. contg. H) or substances such as steam and CO which yield H under the reaction conditions, in the presence of a catalytic mass comprising finely divided absorption carbon or coal such as finely divided brown coal intimately mixed with Mo or Mo compds. Several examples with details are given.

Separating olefins. C. G. HARRIS and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,787, Oct. 24, 1929. Olefins such as C_2H_4 and C_3H_6 are sepd. by means of a solid adsorbent such as active C, previously charged with a vapor such as water vapor, having an affinity for the adsorbent greater than that of one of the olefins to be sepd. and less than that of the other.

Polymerizing olefins. N.-V. DE BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit. 331,186, March 18, 1929. C_2H_4 and its homologs are polymerized by heating them

under pressure without catalysts but in the presence of an inert liquid such as mineral oils, vegetable oils and their products, *e. g.*, C_2H_4 is heated with paraffin oil to 420° under 45 atm. pressure. The treatment may be applied to cracked petroleum products or destructive hydrogenation products of olefinic character.

Diolefins from alcohols. S. V. Lébédev. Brit. 331,482, Jan. 30, 1929. Alcs. such as EtOH, MeOH and PrOH are heated in the presence of a dehydrating catalyst and a dehydrogenating catalyst (suitably ZnO and Al_2O_3 at 400°), preferably under reduced pressure. The reaction products may be passed into Br after cooling, the bromides fractionally distd. and the residual tetrabromide converted into butadiene as by reduction with ZnO in alc. soln. Cf. *C. A.* 24, 1390.

Gelatinized alcohol. H. Ohle. Brit. 331,922, April 12, 1929. K salts of the sulfuric acid half esters of α- and β-diacetonefructose, which may be used for gelatinizing alc., are made by treating α- or β-diacetonefructose at low temps. (suitably −15°) with pyridine and chlorosulfonic acid. After standing, excess pyridine may be distd., the residue absorbed by warm potash soln. and on cooling to 0° the K salt seps.

Aldehydes from alcohols. I. G. Farbenind. A.-G. Brit. 331,883, April 11, 1929. Aldehydes and H are produced by passing vapors of alcs. such as EtOH, BuOH or PrOH over Cu which has been prepd. from Cu carbonate or other compds. by reduction at temps. below redness, activated with oxides such as those of Cr, Mn, Mg and Zn or phosphates such as secondary Na phosphate or tertiary Ba phosphate.

Aldehydes from α-oxides. I. G. Farbenind. A.-G. Brit. 331,185, March 18, 1929. Oxides such as 1,2-propylene oxide, 2,3-butylene oxide or ethylene oxide are passed in vapor form at elevated temps. (suitably 150–450°) over catalysts comprising oxyacids of elements of the 5th or 6th periodic groups or anhydrides or salts of such acids, such as Mg pyrophosphate mixed with kieselguhr or a catalyst formed from Ce sulfate and $Ba(OH)_2$ or from Cu carbonate and Mg NH_4 phosphate. Various details and examples are given.

Esters from glycerol and higher fatty acids. I. G. Farbenind. A.-G. Brit. 332,267, March 18, 1929. In esterifications such as that of olive oil fatty acids with glycerol, the liquid materials are caused to flow, while being heated, through a tower filled with coke or other suitable contact material of large superficial area, under reduced pressure and in the presence of esterification catalysts. App. and various details of procedure are described.

Ethyl esters. Arthur R. Cade (to Carbide and Carbon Chemicals Corp.). U. S. 1,781,050, Nov. 11. Et_2SO_4 is caused to react with a Na salt of an org. acid such as Na benzoate in the presence of ethyl benzoate or other suitable solvent substantially free from water, comprising a preformed portion of the ester to be prepd.

Metal amino carbonyls. Philip S. Danner and John E. Muth (to Standard Oil Co. of Calif.). U. S. 1,780,643, Nov. 4. By heating the reacting materials in a closed vessel there may be obtained Fe diethylamino pentacarbonyl from Fe pentacarbonyl and diethylamine, and substances of equiv. nature to the Fe diethylamino pentacarbonyl which can be produced by the reaction of other metal carbonyls such as Fe tetracarbonyl, Fe nonacarbonyl, Co tricarbonyl, Co tetracarbonyl, Ni tetracarbonyl, Mo hexacarbonyl, etc., and other NH_3 compds. including NH_3 and the aliphatic and aliphatic-aromatic amines, etc.

Nitriles. I. G. Farbenind. A.-G. Brit. 332,258, March 18, 1929. Acetonitrile and its homologs (which may be hydrogenated or hydrolyzed to obtain amines or acids) are obtained by passing mixts. of C_2H_2 with NH_3 or amines over a compd. or mixt. of compds. of metals of the second to seventh group of the periodic system, not reducible under the conditions of working, at a velocity not exceeding 50 l. of C_2H_2 per hr. per l. of catalyst, at temps. of 200–600° (usually about 400° in various examples given). A small quantity of moisture improves the life of the catalyst and for the latter there may be used $ZnSO_4$ on silica gel, oxides of Zn and Th on silica gel, Zn and Cr oxides or $ZnCl_2$, etc. Numerous details of procedure are given. Cf. *C. A.* 24, 3249.

Phenol compounds from dihydroxydiphenylmethane derivatives. Hans Jordan (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,778,858, Oct. 21. A deriv. of 2-hydroxydiphenylmethane is treated with H under pressure in the presence of a hydrogenation catalyst such as a Ni catalyst contg. Bi, at a temp. of about 160° until 2 H atoms have been fixed. Examples are given of the production of phenol and *p*-ethylphenol from *p*-dihydroxydiphenylmethylmethane, *p*-cresol and PhOH from *p*-dihydroxydiphenylmethane and *p*-benzylphenol and PhOH from *p*-dihydroxytriphenylmethane.

Organo arsenic and antimony compounds. H. J. Barber and May & Baker,

LTD. Brit. 331, 869, March 8, 1929. One mol. proportion of an arsinic or stibinic acid is condensed with 4 mol. proportions of an org. mercapto compd., of which 2 mol. proportions serve to reduce the quinquevalent As or Sb to tervalent form while the remainder then condenses with the reduction product to form the thioarsenite or thioantimonite. Examples are given of the production of 8-acetylamino-3-hydroxy-1,4-benzisoxazine-6-dicarboxymethylthioarsenious acid, *N*-phenylglycinamide-4-dicarboxymethylthioarsenious acid, 3-amino-4-hydroxyphenyldicarbamidomethylthioarsenious acid, 4-aminophenyldicarbethoxymethylthioarsenious acid, 3-amino-4-hydroxyphenyldi-β-amino-β-carboxyethylthioarsenious acid, 8-acetylamino-3-hydroxy-1,4-benzisoxazine-6-di-β-hydroxyethylthioarsenious acid, 2-hydroxy-5-acetylaminophenyldicarboxymethylthioarsenious acid, 4-aminophenyldicarbamidomethylthioantimonious acid and 4-chlorophenyldicarbamidomethylthioantimonious acid.

Triaryl phosphates. WILFRID GIBSON and CHARLES R. HENSHAW (to Imperial Chemical Industries, Ltd.). U. S. 1,781,225, Nov. 11. Purification of a crude triaryl phosphate is effected by treatment with oleum contg. about 20% free SO_3.

Concentrating aliphatic acids such as propionic acid. SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Brit. 331,637, March 20, 1929. The process for concg. HOAc as described in Brit. 312,046 (*C. A.* **24**, 863) is applied to the concn. of solns. of other aliphatic acids; *e. g.*, propionic acid may be extd. with Bu propionate and the ext. dehydrated by distn. with an entraining liquid consisting of a petroleum fraction b. 138–40°; or aq. formic acid may be extd. with Am formate and distd. with heptane. Various details of distn. and sepn. of the distn. products are described.

Naphthalene-2,3-dicarboxylic acid. I. G. FARBENIND. A.-G. Brit. 332,122, Sept. 10, 1929. See Fr. 682,474 (*C. A.* **24**, 4306).

Acetyl-Cleve's acid. WALTER M. RALPH (to National Aniline & Chemical Co.). U. S. 1,778,914, Oct. 21. Reaction is effected between Cleve's acid and glacial HOAc in the presence of a salt of HOAc such as NaOAc.

Acetylene recovery from gaseous mixtures. P. H. HULL and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,610, April 20, 1929. The gaseous mixts. are washed with glycol diacetate or an aq. soln. of H_2SO_4 and $HgSO_4$ or other suitable C_2H_2 solvent in a plurality of stages, with increase of pressure between the stages while the partial pressure of C_2H_2 is maintained at 2 atm. or lower. Various details of procedure are described.

Acetylene recovery from gaseous mixtures. G. F. HORSLEY, F. ROFFEY and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,654, May 24, 1929. In a process which may be carried out in stages, a solvent for C_2H_2 is used comprising glycol monoformate, glycol mono- and di-alkyl ethers, glycerol mono- and diacetates, Et lactate or similar compds.

Acetone from acetylene. JEROME MARTIN and IGNACE J. KRCHMA (to Commercial Solvents Corp.). U. S. 1,779,676, Oct. 28. A gaseous mixt. comprising C_2H_2 and an excess of water vapor is passed, at temps. of 275–725° (suitably about 500°) over catalysts such as one initially comprising ZnO, Cr oxide, Fe oxide and $ZnCl_2$.

Benzaldehyde and other oxidation products of toluene. GAS LIGHT & COKE CO., W. G. ADAM, W. V. SHANNAN and M. CUCKNEY. Brit. 331,525, Jan. 29, 1929. A reaction mixt. contg. an excess of toluene is used (suitably in admixt. with water vapor and effluent gases from the reaction) in production of benzaldehyde or benzoic acid or both, a small quantity of maleic acid also being formed. Numerous details of app. and procedure are given.

2-Hydroxy compounds of pyridine. CURT RÄTH (to Schering-Kahlbaum A.-G.). U. S. 1,778,784, Oct. 21. A halopyridine or a deriv. having non-saponifiable substituents is treated with acid-reacting saponifying agents such as HCl (preferably by heating, suitably at about 150°), as in the production of 2-hydroxy-5-nitropyridine from 2-chloro-5-nitropyridine, 2-hydroxypyridine from 2-chloropyridine, 2-hydroxy-5-chloropyridine from 2,5-dichloropyridine or of 2-hydroxy-3-chloro-5-nitropyridine from 2,3-dichloro-5-nitropyridine (details of the production of each of which are given).

Apparatus for polymerization of butadiene, vinyl bromide, styrol, indene, etc. I. G. FARBENIND. A.-G. Brit. 331,265, March 23, 1929. The chamber in which the polymerizing agent is contained is combined with a compensating chamber not contg. such agent into which the liquid may distil in the event of violent reaction and from which it may be returned after cessation of the violent reaction. Various details of app. are described.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

FRANK P. UNDERHILL

Production of lenticular opacities by ultra-violet radiation in the presence of certain salts. MARIE A. HINRICHS. *Proc. Soc. Exptl. Biol. Med.* **27**, 535–8(1930).—The expts. included the exposure to ultra-violet radiation of excised lenses in 0.1% to 1% solns. of NaCl and $CaCl_2$, of eyes of intact living frogs, and of lenses of developing chick embryos. The primary effect of radiation is probably a surface phenomenon which involves the change in permeability to salts or their ions, with a subsequent pptn. of lens proteins. Ca is more effective in producing opacity than Na. C. V. BAILEY

The cholesterol content of the blood and ultra-violet light. T. ORNSTEIN. *Compt. rend. soc. biol.* **103**, 190–1(1930).—Treatment of 25 patients with ultra-violet light had no effect on the cholesterol content of the blood; the variations were within physiol. limits. B. C. BRUNSTETTER

Comparative investigations on the cleavage of peptones and polypeptides by the enzymes of the pancreas. R. SCHÖNFELD-REINER. *Fermentforschung* **12**, 67–127 (1930).—The enzymic cleavage of several peptones, the 2 dipeptides glycylglycine and *dl*-leucylglycine and the tripeptide *dl*-leucylglycylglycine, by variously treated macerations and by a dry prepn. of pancreas, was compared under different conditions for the purpose of detg. the enzyme carriers involved. The system of dipeptide cleavage could be distinguished from that of higher peptide or peptone cleavage, by Fodor's method of acid coagulation and by the sepn. of the dry prepn. into an insol. and a sol. portion. The acid coagulum and the insol. portion of the prepn. were found to be the enzyme carriers in the cleavage of dipeptides and of the dipeptide complex of peptone. The filtrate from the acid coagulum and the sol. portion of the prepn. were active toward the tripeptide and the peptones exclusively. In the autolysis of this sol. portion the power of dipeptide cleavage subsequently develops, apparently by autocatalysis. Kinetic measurements showed that fresh macerations give a linear reaction in the peptone cleavage, while aged macerations and acid filtrates give a parabolic reaction. This is attributed to the different natures of the carriers concerned. The optimal p_H of peptone cleavage by the sol. portion of the pancreatin prepn. is 7.58, while that of dipeptide cleavage by the insol. portion is 7.96 and that of peptone cleavage by the same portion is 8.00. The aging of macerates yields autolytic decompn. products which accumulate even in the digestion of substrate. Under favorable conditions these products exert a promoting influence on peptone cleavage, but they invariably inhibit dipeptide cleavage. Dialysis reverses this effect, and by removal of the sol. substances brings about an inhibition of peptone cleavage and an increase in dipeptide cleavage. A preliminary treatment with glycine influences both peptone and dipeptide cleavage according to the enzyme medium, the temp. and the quantity present. An attempt was made to interpret uniformly the multiplicity of phenomena on the assumption of different enzyme carriers or exchange of carriers. Despite the differentiation between cleavage of dipeptides and that of higher peptides and peptones, the view that sp. enzymes exist for both activities is rejected on theoretical grounds. A. W. DOX

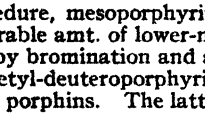
Experimental studies on nuclein metabolism. XXV. Specificity of the Dische color reactions with diphenylamine and carbazole for the purine and pyrimidine nucleosides of thymonucleic acid. MARIANNE ANGERMANN AND FRANZ BIELSCHOWSKY. *Z. physiol. Chem.* **191**, 123–5(1930); cf. *C. A.* **24**, 4794.—Dische's inference (*C. A.* **24**, 1879) that the sugar linked to purine bases is different from that linked to pyrimidines could not be corroborated. The difference in color reaction is due to the fact that the nucleoside linkage of pyrimidines is much more resistant to hydrolysis than that of purines. The great advantage of Dische's Ph_2NH reaction in contrast to the orcinol reaction is that it distinguishes between yeast and thymonucleic acid and their decompn. products. Possibly the blue color obtained with thymonucleic acid and thymosine, as contrasted to the green color with yeast nucleic acid and its nucleosides, is a reaction characteristic of desoxy sugars. Digitalis leaves, which are said to contain a desoxy sugar, gave a Ph_2NH reaction in which the color was more bluish than the green obtained with ordinary sugars of the glucose and arabinose type. A. W. DOX

Remarks on the paper of Angermann and Bielschowsky: The question of the specificity of Dische's color reactions for the purine and pyrimidine nucleosides of thymonucleic acid. ZACHARIAS DISCHE. *Z. physiol. Chem.* **192**, 58–60(1930).—The failure

of A. and B. to obtain the identical color reactions described by D. is due to a departure from the optimum conditions of concn. and time of heating. Their conclusion that the carbazole reaction of thymonucleic acid is not due to the carbohydrate of the pyrimidine nucleosides but to other components is erroneous. Yeast nucleic acid which contains the same components except the carbohydrate and the thymine gives a color reaction 35% less intense. By heating thymonucleic acid 3 hrs. at 135° the carbohydrate is converted into levulinic acid and the other constituents are left intact, yet the color reaction of this hydrolyzate is neg. The carbohydrate responsible for the carbazole reaction is probably present as an unknown nucleotide. This might also explain why removal of carbohydrates by extg. liver and kidney with Cl_3CCO_2H, dissolving the residue in 2% NaOH and pptg. the nucleic acid with HCl, yields a filtrate which gives an intense carbazole reaction and a neg. Ph_2NH reaction. The filtrate probably contains the same substances which are responsible for the carbazole reaction of thymonucleic acid. Cf. preceding abstr. A. W. Dox

Plasmalogen. II. A convenient method for the preparation of plasmal; cleavage of plasmalthiosemicarbazone. M. Behrens. *Z. physiol. Chem.* **191**, 183–6(1930); cf. *C. A.* **23**, 1912.—Plasmal, the mixt. of higher aliphatic aldehydes obtained by decompn. of the plasmalogen present in a lipoid emulsion from horse meat, was previously sepd. by steam distn. This procedure is laborious and time-consuming because the distn. must be made with a large no. of small portions separately, and is open to the objection that the product thus obtained may represent secondary decompn. products. A more satisfactory and convenient method of prepg. plasmal consists in warming the emulsion to 40°, acidifying with 5 *N* H_2SO_4 (20 cc. per l.) and allowing to stand 4 hrs. in the thermostat. The mixt. is then neutralized by shaking with 10 g. $CaCO_3$, 2 g. of $H_2NCSNHNH_2$ is added, and the mixt. shaken frequently during 2–3 days. It is evapd. *in vacuo*, the residue dissolved in Et_2O and dild. with EtOH. The centrifuged soln. is pptd. with alc. $AgNO_3$, the ppt. dissolved in Et_2O and repptd. by EtOH. The Ag compd. is suspended in EtOH, decompd. by H_2S, and the filtrate pptd. by addn. of H_2O. The resulting plasmal thiosemicarbazone is dried *in vacuo* over H_2SO_4, extd. with Et_2O and recrystd. from EtOH and from xylene. The yield from 1 l. of emulsion is 1–1.5 g. of a product, m. 106–7°. The thiosemicarbazone may be hydrolyzed and the plasmal obtained therefrom by steam distn. in the presence of 2 *N* H_2SO_4; the product is collected on a cotton wad and the latter extd. with EtOH. A. W. Dox

The intermediary metabolism of histidine. II. S. Edlbacher, J. Kraus and N. Scheurich. *Z. physiol. Chem.* **191**, 225–42(1930); cf. *C. A.* **20**, 3722.—Histidase has thus far been found only in the liver and its purification is too far from complete to make possible the quant. isolation of all the products resulting from its action on histidine. The unit arbitrarily selected is the quantity of enzyme which liberates 8 cc. of 0.02 *N* NH_3 from 20 cc. of a histidine soln. in 6 hrs. The 1st step in purification of the enzyme consists in centrifuging the aq. suspension, the entire quantity of enzyme remaining in the soln. Adsorption on $Al(OH)_3$ and kaolin from acid medium, followed by elution with Na_2HPO_4, increases the purity 2.5 times with recovery of 40% of the original activity. Histidase retains its activity after several days in the thermostat. Attempts to remove impurities by trypsin digestion destroyed the activity. Dialysis caused a sepn. into less active components which regained the full activity when recombined. The decompn. of histidine by histidase is an anaerobic process. The products are $2NH_3$, 1 *d*-glutamic acid and probably $1CH_2O_2$. Since the cleavage does not involve an asymmetric C it may be assumed that *l*-histidine and *d*-glutamic acid belong to the same steric series. Other products such as urea and CO_2 are in all probability not formed. The cleavage undoubtedly occurs through intermediate stages, the most plausible one being pyrrolidonecarboxylic acid. Histidase is highly specific. It hydrolyzes only the naturally occurring *l*-histidine, and is without action on imidazole, imidazolyllactic acid, imidazolylethylamine, methylhistidine and probably also carnosine and histidine Me ester. A. W. Dox



Enzymic cleavage of lecithin. Hazel King, Earl J. King and Irvine H. Page. *Z. physiol. Chem.* **191**, 243–50(1930).—Exts. of various organs, especially intestine and kidney, hydrolyze lecithin emulsions at an optimum p_H of 7.4–7.6 with a splitting off of H_3PO_4. The concn., both of substrate and of enzyme, has a special influence on the extent of hydrolysis, so that beyond a certain limit an increase in concn. results in decreased cleavage. Exts. of bone and liver contain very little lecithin-splitting enzyme. This is noteworthy in view of the high content of phosphatase in bone ext. A. W. D.

The porphyrins. XXVI. Hemoporphyrin. H. Fischer, Hans Helberger and Georg Hummel. *Z. physiol. Chem.* **191**, 251–61(1930); cf. *C. A.* **24**, 4794.—Willstätter's hemoporphyrin, obtained by treatment of hematoporphyrin with alc.

KOH in the presence of MgO and removal of the Mg from the phyllin thus formed, is shown to be a mixt. instead of an individual substance. At least 3 reactions are involved in the process of prepn. First there is formation of mesoporphyrin in good yield by the reducing action of the alcoholate. There is also a partial splitting off of 1 or both CHOHMe and replacement by H. The product here is deuteroporphyrin. In addn. to this cleavage reaction whereby both CHOHMe side chains are removed, a combination of the 2 reactions results in formation of the 2 isomeric porphins, where 1CHOHMe is replaced by H and the other reduced to Et. This is shown by their oxidation to a mixt. of methylethylmaleic imide and citraconimide. In the prepn. of hemoporphyrin by Willstätter's procedure, mesoporphyrin was isolated without difficulty. There was also present a considerable amt. of lower-melting esters representing at least 3 porphyrins. This was shown by bromination and acetylation of the hemoporphyrin, which yielded dibromo- and diacetyl-deuteroporphyrin, and also the Ac derivs. of the 2 tetramethylethyldipropionic acid porphins. The latter are derivs. of etioporphyrin III.

The artificial building up of bones and teeth. I. Preparation of glycine-hexol salt, or glycine-phosphato calcium carbonate. Th. Gassmann. *Z. physiol. Chem.* **192**, 61–9(1930); cf. *C. A.* **23**, 1652.—The main constituent of bones and teeth,

can be prepd. not only with Na_2HPO_4, as previously shown, but also with glucose-phosphoric acid and the H_3PO_4 obtained therefrom by enzymic cleavage, if the synthesis is performed at body temp. of 38–40°. At the same time glycine can be united to this compd. The glycine-hexol salt, $(Ca[(HO)_2Ca]_3)CO_3.NH_2CH_2CO_2H$, was also prepd., but this is less sol. in distd. H_2O. Glycine cannot be leached out from either of these compds. by distd. H_2O. Both syntheses are best performed by the use of natural ice water, in which a P compd. is present. The stability of the glycine addn. products is regarded as an affirmative answer to the long-debated question whether or not the org. substance of bones and teeth is in chem. combination with the phosphatocalcium carbonate.

A. W. Dox

The active group of liver catalase. Karl Zeile and Harry Hellström. *Z. physiol. Chem.* **192**, 171–92(1930).—The catalse activity of hemin, recently reported by Kuhn (*C. A.* **21**, 3061) and others, has suggested a possible connection between the catalase of animal and plant tissues and the porphyrin-Fe complex which invariably accompanies it. However, the activity of the purest liver catalase is some 10,000 times greater than that of the same quantity of hemin, so that if a porphyrin-Fe complex is essential to the enzymic activity it must be of a specific nature. A proportionality should then exist between enzymic activity and porphyrin Fe content of the prepn. as shown by its hemochromogen spectrum. In detg. this ratio it is important to use prepns. that have been freed from hemoglobin and its decompn. products. This was accomplished by emulsifying the liver ext. with $CHCl_3$, adding EtOH to 50% and centrifuging. The hemoglobin then forms a solid cake between the 2 liquid phases. The aq. layer contains all of the catalase and shows no hemoglobin spectrum, but after treatment with NaOH, pyridine and $Na_2S_2O_4$ it gives a strong spectrum of hemochromogen. This indicates the presence of a porphyrin-Fe complex independent of the occurrence of hemoglobin. The spectrum of this porphyrin resembles that of alk. hematin except for a uniform displacement toward the red. Unlike hemin, it does not give the hemochromogen spectrum with $Na_2S_2O_4$ and pyridine or Na_2HPO_4, but requires the addn. also of alkali; hence the complex is present in a combined form. Addn. of KCN to the catalase soln. gives an absorption spectrum with 2 bands in the green while the red absorption disappears, thus differing from the corresponding hematin HCN spectrum. A similar difference is noted in the spectrum changes after addn. of H_2S. Various adsorption treatments were given the catalase prepn. to det. whether the ratio between catalase reaction const. and porphyrin-Fe content remains const. or whether a sepn. can be effected. Treatments with $Al(OH)_3$, $Fe(OH)_3$, $Zn(OH)_2$, animal charcoal, kaolin and repeated dialysis failed to alter this ratio of approx. 2500. The porphyrin-Fe complex thus appears to be the carrier of the catalase function. Further evidence is the fact that after partial inactivation the ratio is restored by $Al(OH)_3$ adsorption. The ratio is 10^6 greater than that of ordinary porphyrin-Fe complexes; hence the complex assocd. with the enzyme is highly specific. Treatment of the catalase soln. with a quantity of HCN equiv. to the porphyrin-Fe present suppresses the activity and gives

a quant. spectrum of the HCN compd. Dissocn. of the compd. by diln. restores the original spectrum and the catalase activity at the same rate. Inactivation by H_2S is also reversible. On the other hand, inactivation by $HgCl_2$ is a protein pptn. phenomenon and is not reversible. A. W. Dox

The action of adenosinemonophosphoric acids and adenosinetriphosphoric acid on dehydrogenation processes by plant and animal enzymes. HANS J. DEUTICKE. *Z. physiol. Chem.* **192**, 193–216(1930).—The Thunberg methylene blue method was applied in a study of the dehydrogenase present in the seeds of the jute plant (*Corchorus capsularis*), with org. phosphoric acids as O- donors. The reduction to leuco base through the action of enzyme is accelerated by the hexosediphosphoric acid from muscle as well as that from yeast. The hexosediphosphoric acid which is formed spontaneously in the press juice of glycogen-rich dog muscle and that which is formed in the press juice of rabbit muscle in the presence of NaF had precisely the same influence on the enzyme reaction as the hexosediphosphoric acid from yeast. The methylene blue reduction which occurs after addn. of a boiled ext. of muscle is due to adenosinetriphosphoric acid. There is no evidence of the presence of hexosediphosphoric acid in the freshly dissected muscle. Muscle adenylic acid, which itself does not bring about the reduction of methylene blue, accelerates the reaction in a specific manner if added in low concn. after addn. of hexosediphosphate and especially of hexosemonophosphate (lactacidogen), while it is without influence on the reaction velocity after addn. of adenosinetriphosphate. In higher concns. its action is always inhibitory after addn. of these substances. The action of yeast adenylic acid, on the other hand, is exclusively inhibitory. Dehydrase solns. from muscle are also considerably activated by adenosine-triphosphoric acid in their power to decolorize methylene blue. In this respect adenosinetriphosphoric acid is superior to the hexosediphosphoric acids. With the animal dehydrase solns., in contrast to those from *Corchorus* seeds, the single addn. of muscle adenylic acid (not yeast adenylic acid), inosic acid and the pentosephosphoric acid prepd. therefrom, accelerates the methylene blue reduction. A. W. Dox

Phosphatides. I. The fatty acids of the cephalin fraction of the brain. E. KLENK. *Z. physiol. Chem.* **192**, 217-32(1930).—A complete removal of cerebrosides and sphingomyelin from the cephalin fraction is not possible. The sepn. was therefore accomplished by a mild hydrolysis which split off the fatty acids from the cephalin but left the cerebrosides and sphingomyelin unaltered. The K salts of the satd. fatty acids sep. from the Et_2O soln. and consist mainly of stearic acid with possibly some palmitic acid. The unsatd. acids were esterified with MeOH and H_2SO_4 and the Me esters fractionated by distn. *in vacuo* between 150° and 190°. The 4 fractions thus obtained were hydrogenated with Pd-$BaSO_4$ catalyst, sapond. with *N* KOH in MeOH, and the free acids liberated. These satd. acids were esterified, their esters fractionated and sapond., and the free acids recrystd. They consisted of stearic and behenic acids in the proportions of about 3 to 1. The intermediate member of the series, arachidic acid C_{20}, was not present. This should result from hydrogenation of arachidonic acid, the occurrence of which has been reported by Levene and Rolf (*C. A.* **16**, 3911). The no. of double linkages in the C_{22} acid before hydrogenation has not been accurately detd. The Br content of the Et_2O-insol. Br addn. product and the I no. of the Me ester of the unsatd. acid indicate at least 4 and possibly 5 double linkages. With 5 double bonds the acid would be isomeric and probably identical with the $C_{22}H_{34}O_2$ acid obtained by Tsujimoto (*C. A.* **15**, 1227) from fish oils. Reduction of the Br addn. product gave behenic acid. From 35 g. of cephalin fraction there were obtained 0.2 g. palmitic acid, 8.6 g. stearic acid, and 2.9 g. of behenic acid. Of the stearic acid 3.8 g. belongs to the satd. and 4.8 g. to the unsatd. fraction, while the behenic acid belongs entirely to the unsatd. fraction of the fatty acids. A. W. Dox

Further studies in the formation of a histamine-like substance from histidine by irradiation with ultra-violet light. FRIEDRICH ELLINGER. *Arch. exptl. Path. Pharmakol.* **153**, 120–7(1930); cf. *C. A.* **24**, 1130.—Irradiation of even dry histidine results in the formation of a substance with pharmacol. properties like those of histamine. Such irradiated histidine prevents the decompn. of histamine by ultra-violet light, because of a yellow tint in the soln. H. EAGLE

Physiological and chemical experiments with ultra-violet rays through glass and also a method of evaluation. H. VALENTIN. *Pharm. Ztg.* **75**, 982–4, 995–8, 1005–8 (1930).—A study has been made of certain chem. and biol. effects produced in a school, hospital and prison on plant and animal organisms, also on a variety of chemicals, by ultra-violet light passed through ordinary and special glass. With pupils subjected to such treatment, a marked darkening of the skin and slight increase in well-being were noted. No increase in hemoglobin count could be detected. With plant seeds behind

ultra-violet glass a notable increase in the germination process was observed. Rapidity of growth, however, was only 10% greater than in plants under ordinary glass. Ultra-violet rays inhibit markedly and even cause recession in the growth of fungi and yeast cultures. Changes in a large no. of chem. compds. are largely effected by ultra-violet light, which, however, is not the sole "chem. active" rays. Certain decompns. are produced by the visible sunlight. There are at present many different brands of glass permitting the passage of ultra-violet rays, but in varying degree. The suggestion is therefore made that the quality of any such glass be definitely ascertained prior to purchase. A criticism is made of the glass (ultravit) installed in the municipal institutions of Königsberg, as possibly explaining the not altogether satisfactory results obtained in the schools and on plants. Of all the varieties of glass investigated, that of Schott und Gen. (Uviolglas) proved to be the best and cheapest. The value of an ultra-violet glass may be detd. as follows: In a crystg. dish (*a*) contg. a few cc. of KNO_3 soln., cover with the sample of glass plate under examn., sealing the circle of contact air-tight with desiccator fat. Into a SiO_2 flask (*b*) introduce also a like amt. of KNO_3 soln. and close this air-tight. Now expose both containers in the open about 1 week or 10 min. to the rays of an analytical quartz lamp. Thereupon det. with Gries' reagent and a control soln. of KNO_3 colorimetrically the amt. of nitrite formed. In the soln. (*a*) about 75% of the HNO_2 formed in (*b*) should be present. W. O. E.

Effect of Röntgen and radium irradiation on metabolism of women with carcinoma of the uterus. E. O. GAESSLER. *Strahlentherapie* **37**, 361–77(1930).—In carcinoma of the uterus the metabolic disturbances consist in a lowering of the alkali reserve, and of the surface tension, in an increase of the plasma vol. and of the total albumin, of the fibrinogen and of globulin, also an increase of the blood fat and the K; often even amino acids, lactic acid and blood sugar are considerably increased. Röntgen rays ordinarily increase the alkali reserve; they always increase the vol. of the plasma and the albumin of the plasma. Fibrinogen, globulin and albumin show a varying behavior. The Röntgen irradiation regularly produces an increase in the Ca content of the blood. There is a regular decrease in cholesterol, in the surface tension and in the blood fat. The radium treatment also increases the plasma vol.; sometimes it increases the fibrinogen and globulin, but as a rule it does not exercise a regular influence upon the metabolism of the patient. F. R. GREENBAUM

The elimination of nitrogen in urine after Röntgen and radium ray treatment. GUNTHER K. F. SCHULTZE. *Strahlentherapie* **37**, 642–58(1930).—S. studied the elimination of N in the urine of patients that were treated with Röntgen and Ra-rays. He found that after Röntgen-ray treatment in about 50% of the cases a distinct increase of the N elimination in the urine occurred. This increase would be stronger if a Ra treatment had preceded this Röntgen radiation about 3 to 4 weeks. After Ra treatment in all cases an increase of the elimination of N in the urine occurred. This increase was found to be more const. and greater than that after Röntgen radiation. S. in contrast to other investigators found that the creatinine N is not responsible for the increased elimination of the total N. This observation of the increased elimination of N in the urine is not as yet suitable for a prognosis of the disease, as it is too inconst., depending upon the types of diseases, the technic of radiation and the doses. F. R. GREENBAUM

The blood-sugar regulation under Röntgen rays. A. HELD. *Strahlentherapie* **38**, 27–39(1930).—H. distinguishes between general action of the rays on the blood-sugar regulation and the direct action of the sugar transformation in the irradiated region. The direct action of the rays upon the blood-sugar regulation, which is shown in hyperglucemia, is due to reaction products formed by the action of the rays. This can be demonstrated by the re-injection of the blood of the patient, who has been radiated, in his own blood stream, which will also produce hyperglucemia. The causative factors seem to lie in the increased H-ion concn., the transmineralization and the degeneration products of albumin. The direct action of the rays is examd. by the comparison between the content of the blood sugar in the capillaries (arteries) and the veins of the radiated and non-radiated rear extremity. H. demonstrated that the muscle cells take active part in the blood-sugar regulation. In the region of absorption of the rays a relative hyperglucemia will occur, which can be considered as direct action of the rays. H. believes the influence of the rays is due to a change in permeability, to the oxidative metabolism, to the process of formation of lactic acid and to the diastatic process. No abs. proof for any one of these changes is offered by H.'s expts. F. R. GREENBAUM

The biologic action of Röntgen rays. PH. ELLINGER AND E. GRUHN. *Strahlentherapie* **38**, 58–97(1930).—The authors studied the action of secondary rays of various kinds upon photographic emulsions and *Bacterium prodigiosum*. The blackening effect of secondary rays upon a photographic plate depends upon the density of the

primary rays, that is, the blackening effect of secondary rays increases with increasing density of primary rays. It also depends upon the atom no. of the secondary rays, namely, it increases with increasing atom no. Filter expts. with Al foils showed that the effect of secondary radiation upon the photographic plate depends upon the high permeability of the secondary rays, which most likely is produced by fluorescent rays of various series. Cultures of *Bacterium prodigiosum* are only damaged by primary Röntgen rays of various wave lengths when the doses exceed 500R. In the region of 1000 to 3000R the bacteria are killed with increasing dosage. However, a certain percentage even survives with doses as high as 15000R. If secondary rays of high atom no., however, are employed a rapid destruction of the bacteria occurs, even with small doses of primary rays and with doses of about 300R complete inhibition and sterilization occurs. Primary rays with varying wave lengths have the greatest inhibition action at medium wave length. With secondary rays the inhibitive action increases with increasing wave length. The bactericidal action of pure primary rays depends to a slight extent upon the density of the rays. Rays with a smaller density produce a greater effect than rays with greater density. Secondary rays do not depend upon the density of the primary rays. The bactericidal action of the secondary rays increases with increasing atom no. The bactericidal active rays possess very small permeability. They are absorbed by a layer of air of 4–5 millimeters. The most active rays have the least permeability. Conclusion: The bactericidal actions of the Röntgen rays are based primarily upon photoelectrons of first and second order. The bactericidal action of secondary rays remains at a dilution of secondary rays to about 1%. F. R. G.

The sensibilizing action of hemato porphyrin toward Röntgen rays. N A. PODKAMINSKII. *Strahlentherapie* **38**, 98–102(1930).—P. found that hematoporphyrin acts as a sensibilizer for Röntgen rays. After injection of hematoporphyrin and succeeding Röntgen ray treatment subacute and chronic forms of the "Röntgen disease" analogous to the "light disease" have been observed. The sensibilizing action of hematoporphyrin can be expected wherever an action of Röntgen rays upon hematoporphyrin occurs, and therefore favorable results may be expected not only on the surface but also on deeply imbedded organs. F. R. GREENBAUM

The relation of cholesterol metabolism and the after-effects of x-ray treatment. RUDOLF HUMMEL. *Strahlentherapie* **38**, 308–314(1930).—H. points out that, after Röntgen treatment of patients, a decrease of the cholesterol content of the serum occurs. In some cases there is also an increase. The decrease of the cholesterol in the serum does not go parallel with the after-effects of the x-ray treatment. The decrease of the cholesterol in the blood seems to coincide with the after-effects of the x-ray treatment. In using "Colsil" (a drug prepd. by Landshoff & Meyer, Germany) only in 1/4 of the cases intoxication of the x-ray treatment could be obtained. F. R. GREENBAUM

Inactivation of pancreatic lipase by heat. IVOR H. MCGILLIVRAY. *Biochem J.* **24**, 891–904(1930).—The p_H of optimum stability of purified pancreatic lipase does not coincide with its "optimum p_H" (that is, the p_H, of optimum activity upon a substrate). The optimum thermal stability is in the region of p_H 6.0, whereas the "optimum p_H" is 8.0. The heat inactivation of purified lipase has a relatively low value (46,000 calories). BENJAMIN HARROW

Specific refraction increments of serum albumin and serum globulin. GILBERT S. ADAIR AND MURIEL ELAINE ROBINSON. *Biochem. J.* **24**, 993–1011(1930).—The n of a protein soln. is greater than that of pure water, and the difference between the refractions of the protein soln. and the solvent is equal to the protein concn. in g. per 100 cc. soln., multiplied by a const. (which is known as the specific refraction increment (*s.r.i.*)). Various samples of purified horse serum albumin, prepd. by Hopkins' method (*J. Physiol.* **25**, 306(1900)), showed a const. *s.r.i.*, unaffected by recrystn. The theoretical significance of *s.r.i.* is discussed. BENJAMIN HARROW

Action of pepsin on gelatin. ROBERT K. CANNAN AND EDWARD MUNTWYLER. *Biochem. J.* **24**, 1012–20(1930).—With the aid of H electrode titration curves, it is shown that peptic acid results in the hydrolysis of peptide linkages between the α-amino and α-carboxyl-groups. BENJAMIN HARROW

Chemistry of estrin. IV. The chemical nature of crystalline preparations. GUY F. MARRIAN. *Biochem. J.* **24**, 1021–30(1930); cf. *C. A.* **24**, 5315.—The substance isolated, m. 264–6°, is strongly *d*-rotatory ($[\alpha]_{5461} = +38°$), and has the mol. formula $C_{18}H_{24}O_3$. It is weakly acid, being sol. in alkali and pptd. by CO_2. Three OH groups can be acetylated. From the base-binding power and approx. p_K of the substance, 1OH group is acidic. The phenol color reactions are pos. Conclusion: A hydroxyphenyl radical is present in the mol. The substance obtained from an alk. soln. with CO_2 is

identical with that obtained by sapon. of the acetate. It is not appreciably volatile at 165° and 0.001 mm. Hg. BENJAMIN HARROW

Action of arsenate on hexosephosphatase. MARJORIE GIFFEN MACFARLANE. *Biochem. J.* **24**, 1051–7(1930).—Hexosemono- and di-phosphate can be hydrolyzed by washed dried yeast in the absence of coenzyme. The accelerating action of arsenate on the rate of production of phosphate from hexosediphosphate takes place only in the presence of yeast ext. BENJAMIN HARROW

Production of the methylglyoxal and pyruvic acid step of alcoholic sugar cleavage as a demonstration experiment. CARL NEUBERG AND MARIA KOBEL. *Ber.* **63B**, 1986–9 (1930).—The nearly quant. conversion of hexose to methylglyoxal (I) and pyruvic acid (II) as postulated as a step in the Neuberg fermentation mechanism has been accomplished *in vitro*. Since the first step of the process is the phosphorylation of the hexose by the action of a coenzyme and since the same or a closely related enzyme brings about further changes in I after its formation, the expt. must be begun with hexosediphosphate and the coenzyme removed or weakened to permit I to accumulate. The destruction of coenzyme is accomplished by adding a plasmolyzing agent to the mixt. of Mg hexosediphosphate (III) and fresh top yeast. I or II results as the main product according as the ratio between the amt. of yeast is smaller or greater in proportion to substrate, resp. Thirty cc. 8% soln. of III with 0.5 g. fresh top yeast and 1–2 cc. toluene in a glass-stoppered flask were kept at 37° in a thermostat for 1–2 days. A 10-cc. sample was removed, protein pptd. with 2 cc. 20% trichloroacetic acid, filtered and the I pptd. with 2 cc. of a soln. of 0.5 g. of 2,4-dinitrophenylhydrazine in 30 cc. 2 *N* HCl. After 1–1½ hrs., during which period no osazones of hexose had yet pptd., the methylglyoxal-bis-2,4-dinitrophenylhydrazone was filtered and washed with ½ *N* HCl and water. Traces of pyruvic acid hydrazone were washed out with 20% soda soln. The procedure for obtaining mainly II was identical except that 6 times the quantity of yeast or 3 g. was used. The pyruvic acid 2,4-dinitrophenylhydrazone was isolated by dissolving the first ppt. in 3–5 cc. of 20% soda soln., filtering and repptg. by neutralizing with ½ *N* HCl. Since yeasts vary in activity, a longer period of reaction is required by some to give a good yield. The formation of II involves oxidation of one-half the hexose at the expense of the other half so that glycerol is produced with II. R. C. HOCKETT

Vitamin content of marine plankton. F. S. RUSSELL. *Nature* **126**, 472(1930).—In April, May and June most of the plankton animals in Plymouth (England) waters live at depths below 10–15 meters; in July, August and September certain species previously found only in the deeper layers become abundant right up to the surface, where irradiation can occur. This seems significant in view of the findings of Belloc, Fabre and Simmonet (cf. *C. A.* **24**, 4794) that plankton sterols collected in July were biologically active, whereas those collected in April acquired biological activity only after irradiation. LOUISE KELLEY

Specific properties of protease and amylase from the standpoint of adsorption phenomena. I. Comparative relation between Taka-diastase and pancreatin. FUMIWO HEMMI AND GORO INAMI. *Bull. Agr. Chem. Soc. Japan* **5**, 49–54(1929).—Adsorption of protease and amylase from Taka-diastase and pancreatin by kaolin and $Al(OH)_3$ was studied with particular regard to the p_H of the dispersion medium. The enzymes of Taka-diastase were adsorbed by $Al(OH)_3$ in amts. 2 to 4 times greater than from pancreatin. Adsorption diagrams with variations in amts. of adsorbent, change of p_H, and acid concn. are given. W. D. LANGLEY

Castor-bean lipase. V. Action of ultra-violet rays on the vegetable oils, from the viewpoint of enzymology. ETUSO TAKAMIYA. *Bull. Agr. Chem. Soc. Japan* **5**, 71 (1929); cf. *C. A.* **24**, 3523.—The change in velocity of hydrolysis of cotton-seed oil by lipase as a result of irradiation was observed. The diminished activity of the enzyme corresponds to that brought about by ozonization, and it is considered that the ultra-violet rays act merely as an ozone generator. W. D. LANGELY

The influence of the photodynamic action of trypaflavine and ultra-violet rays on hair growth. MILIO FERNÁNDEZ BLANCO. *Semana méd.* (Buenos Aires) **1930**, II, 1021–8.—Trypaflavine and eosin have no photodynamic action after injections in white rats. Ultra-violet rays showed no influence on the hair growth. A. E. MEYER

Secretion of digestive enzymes. PIETRO ALBERTONI. *Arch. ital. biol.* **83**, 128–9 (1930).—Expts. with diastase prepns. injected intravenously fail to indicate that these enzymes reappear in the saliva. It is therefore maintained that there is no justification for assuming that digestive enzymes circulate through the system. Whenever these appear in a secretion they are the specific products of different glands. S. M.

The arbutase content of Bacillus mycoides. HELENE GLINKA-CHERNORUTSKA. *Biochem. Z.* **226**, 62–6(1930).—*B. mycoides* when grown on substrate contg. arbutin

splits it into hydroquinone and glucose. The enzyme arbutase is firmly attached to the bacterial cells so that it cannot be obtained by means of the usual methods for the isolation of intracellular enzymes. S. MORGULIS

The mobility of ions in gelatin gels and in nerve substances. VI. The thickness and nature of the semipermeable membranes in irritable tissues. Calculation on the basis of experimental data of the distance traversed by the ions in the first phase of the irritation. V. V. EFIMOV. *Biochem. Z.* **226**, 129–32(1930); cf. *C. A.* **24**, 3026.—Under the influence of an electric impulse causing irritation of the nerve the OH ions traverse a distance of 7.6×10^{-7} cm. or approx. the diam. of a hemoglobin or starch mol. S. MORGULIS

Studies on erepsin. H. A. OELKERS. *Biochem. Z.* **226**, 185–94(1930).—$CaCl_2$ and $MgCl_2$, beginning with a concn. of 0.003 mol., exert an inhibiting effect on the cleavage of alanylglycine by intestinal erepsin at p_H 7.8, and completely suppress in a concn. of 0.5 mol. NaF in concns. of 0.001 to 0.100 mol. and NH_4SCN in concns. of 0.0008 to 0.021 mol. have no effect on the cleavage at p_H 7.8. Both alanine and glycocoll considerably diminish the rate of hydrolysis. S. MORGULIS

Studies on the adsorption of cholesterol. LIDIE LEPIN. *Biochem. Z.* **226**, 195–202(1930).—In studying the adsorption of colloidal cholesterol by charcoal in the presence of HCl or AcH it was found that the adsorption of the cholesterol sol depends upon the amt. of adsorbed acid. The peptization of cholesterol increases with alky. It is believed that in the alk. medium the cholesterol suspension changes chemically, presumably to a metacholesterol. S. MORGULIS

Hydrogen-ion concentration of the interior of the cell of Fusarium lini B. and of yeast. VII. Mechanism of enzyme action. S. MAHDIHASSON. *Biochem. Z.* **226**, 203–8 (1930).—The H-ion concn. of the cell interior of *Fusarium lini* B. and of yeast was detd. by means of microinjections and in the former was found to be p_H 6.0–6.1, while in the latter p_H 5.9–6.0. This finding is in agreement with the results of other observers who showed that the max. enzymic activity also occurs at p_H 6.0. S. MORGULIS

Studies on the structure of silk fibroin. II. EMIL ABDERHALDEN AND HANS BROCKMANN. *Biochem. Z.* **226**, 209–20(1930); cf. *C. A.* **23**, 5478.—Previous analyses of the benzoyl group in benzoyl fibroin compds. have been checked and corroborated by means of halogen detns. on halogenbenzoyl-fibroin compds. Crude silk fibroin fibers treated with 2 *N* NaOH yield in blank detns. benzoyl values whereas this is not the case when purified fibroin is used. *d,l*-Leucylglycine heated to 160–170° for 7 hrs. with *N* NaOH gives in blank detns. a 1.32% benzoyl content. Silk fibroin fibers benzoylated with PhCOCl in pyridine contains more easily hydrolyzable benzoyl than those benzoylated in water. The amt. of benzoyl does not change with the duration of treatment but the fibers become weaker, and such fibers also have a poorer staining capacity. The staining ability can be restored by splitting off the benzoyl groups with dil. alk. Benzoylation can also be accomplished by heating silk fibroin with $PhCO_2H$ in pyridine. Tussa silk is insol. in LiBr and is not acted on by PhCOCl in pyridine. Under the influence of diazomethane on silk fibroin products are formed whose MeO content agrees well with the tyrosine. Under prolonged action, however, the MeO gradually increases to a const. value. The per cent of OH and NH_2 groups which can be calcd. from the MeO and methylimide content of the completely methylated fibroin agree with the values obtained from the benzoyl content. Previous treatment of silk fibroin with *N* NaOH yields products which on benzoylation give the same results as before the alk. treatment, but after a 22 hr. previous treatment an alc.-insol. product is formed characterized by a high content of easily and difficultly saponifiable benzoyl. Silk fibroin dispersed in H_2O is digested by dog stomach juice or by trypsin. Erepsin acts only after preliminary peptic digestion. Most of the trypsin is hydrolyzed by the tryptic digestion. S. M.

Proteolytic cellular enzymes of Egyptian mummies (about 3000 years) and of the mammoth (30,000 to 100,000 years). O. STEPPUN AND XENIA UTKINA-LYUBONTZOVA. *Biochem. Z.* **226**, 237–42(1930).—The 3 characteristic optima at p_H 4.0, 5.5 and 7–8 which have been observed for the intracellular proteolytic enzymes of various living organisms for casein are also corroborated for the Egyptian mummy and the mammoth, *i. e.*, organisms which have been in a state of preservation for 3000 to 100,000 years. The present-day cellular enzymes therefore digest mummy or mammoth proteins as well as the cell substrate of any living organism. Each enzyme of the proteolytic system of the cell is adapted to act upon a certain substrate but the source of the substrate does not matter, and all are equally well digested. S. MORGULIS

Studies on glyoxalase. FUTOSHI SAKUMA. *J. Biochem.* (Japan) **12**, 247–79 (1930).—The glyoxalase content of the liver is highest, the other tissues contg. 30–60% as much as the liver. In animals kept under normal conditions the glyoxalase content

of the tissues varied very little. The chief difference between the cold- and warm-blooded animals is that the former have only half as much glyoxalase in the liver as the latter. When the tissues of the animals have been deprived continuously of their sugar their glyoxalase content likewise was definitely diminished, but the liver lost the enzyme slower than any other tissue. The study of the glyoxalase content of germinating soy beans shows that the glyoxalase content increases rapidly up to the seventh or eighth day and then decreases, the increase being ascribed to the increase of coenzyme rather than that of the enzyme itself. By successive treatment of animal tissues with alc. and ether a dry glyoxalase prepn. was made which could be kept unchanged for at least 4 weeks and represented at least 70% of the original tissue activity. The enzyme could be effectively extd. from the dry powder by shaking with a neutral liquid for an hr. or two depending upon the temp. On dialyzing in a collodion bag against distd. H_2O the glyoxalase soln. lost its activity in 5 hrs. but this could be definitely restored by adding boiled tissue juice. Glucose or polyglucides contg. glucose accelerated the activity of dialyzed or non-dialyzed samples of glyoxalase, which other hexoses did not do. Phosphate inhibited the glyoxalase activity. Guanine and its derivs. and amino acids cause a rapid disappearance of methylglyoxal directly with the production of NH_3 and CO_2. S. MORGULIS

The reactions of cyanide with globin hemochromogen. M. L. ANSON AND A. E. MIRSKY. *J. Gen. Physiol.* **14**, 43–54(1930).—Cyanide reacts with globin hemochromogen (1) without displacing or competing with globin or (2) by displacing globin. The 1st compd. is probably a typical hemochromogen; the 2nd is probably a compd. of cyanide with cyanide hemochromogen. C. H. RICHARDSON

The effect of low pressures on cell oxidation. S. F. COOK. *J. Gen. Physiol.* **14**, 55–70(1930).—The O_2 intake of yeast is reduced to a greater extent by low barometric pressure than by corresponding reduction of the partial pressure of O_2 at atm. pressure. Certain *in vitro* oxidation systems do not show this effect of low pressures. The CO_2 production of yeast is not affected by low pressures. The inhibition of tissue oxidation caused by CO is removed by lowering the pressure. A method for measuring tissue oxidation at reduced barometric pressure is described. C. H. RICHARDSON

The arginine and prearginine groups in edestin. HENRY S. SIMS. *J. Gen. Physiol.* **14**, 87–97(1930).—The dissocn. index of the 3rd group of arginine is $pK_3' = 12.5$ (cf. Schmidt, Kirk and Appleman, *C. A.* **24**, 5577). Titration data of edestin in very alk. solns. indicate a group with titration index $p_{G'} = 12.0$ but present in much smaller quantity than can account for the arginine found on hydrolysis. The theory that the combination of strong base or strong acid with proteins is produced by the formation of salts with "extra groups" of those tervalent acids which can be isolated from the protein, except arginine, is supported by the data. Arginine contributes to the titration curve in much smaller quantity than is found on hydrolysis. This deficiency in the arginine group may be accounted for by the basic group in proteins which have a titration index of $p_{G'} = 3.8$ to 4.6, and which yields arginine on hydrolysis. This may be called prearginine. C. H. RICHARDSON

The combination of edestin with hydrochloric acid. DAVID I. HITCHCOCK. *J. Gen. Physiol.* **14**, 99–103(1930)—Measurements of e. m. f. of cells without liquid junction of the type Ag, AgCl, HCl + protein, H_2, indicate that when dissolved in 0.1 *M* HCl 1 g. edestin (or more probably *edestan*) combines with a max. of 13.4×10^{-4} equivs. of H^+ and 3.9×10^{-4} equivs. of Cl^-. Methods are described. C. H. RICHARDSON

The free energy of glucose and of tripalmitin. HENRY BORSOOK AND HOWARD M. WINEGARDEN. *Proc. Nat. Acad. Sci.* **16**, 559–73(1930).—From the free energy data of Parks, Kelley and Huffmann (*C. A.* **23**, 4877) the theoretical max. work obtainable under physiol. conditions by oxidation of glucose and tripalmitin is computed to be 1.01 and 0.98 of the resp. heats of combustion. For tripalmitin, $-\Delta F_{310} = -211{,}000$ cals. Conversion of tripalmitin into glucose involves a loss of about 21% of the theoretical max. work obtainable, and since the observed difference between the efficiency of carbohydrate and fat, as fuel in animals, is about 11% (cf. Krogh and Lindhard, *C. A.* **14**, 3099), part of the released energy must be available for work, or else fat is utilized as such for muscular work. In plants this is probably not the case (cf. Terroine, Trautmann, and Bonnet, *C. A.* **21**, 3216). K. V. THIMANN

Constitution and electrochemical behavior of protein (PAULI) 2. The variation of electrical resistance with applied potential. II. Thin collodion films (BLINKS) 2. Zwitterions. I. Proof of the Zwitterion constitution of the amino-acid molecule (HARRIS) 2. CO_2 cleavage of pyruvic acid (BOKLUND) 10. Further comparative studies on the influence of *N*-alkali, erepsin and trypsin-kinase on polypeptide-like compounds containing β-aminoisovaleric acid (ABDERHALDEN, REICH) 10.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

A micro determination of blood sugar. R. B. GIBSON. *Proc. Soc. Exptl. Biol. Med.* 27, 480-3(1930).—The detn. is made on 0.2 cc. of blood obtained from a finger tip puncture. Protein and non-sugar reducing substances are pptd. by using about 2.5 times the amt. of Na tungstate and H_2SO_4 over that in the original Folin-Wu procedure in proportion to the vol. of blood used. The arseno-tungstate sugar reagent with added formaldehyde of Benedict (*C. A.* 19, 2352) develops the color which is permanent. The detailed prepn. of the required 5 standard solns. is given along with a table of blood sugar values from colorimetric readings when the standard is set at 10 mm. In 107 specimens of apparently normal venous blood the blood sugar values varied from 66 to 122 mg. with an av. of 91 mg. per 100 cc. of blood. C. V. BAILEY

Sugar in 0.02 cc. blood by the method of Folin and Malmros. J. F. MCCLENDON. *Proc. Soc. Exptl. Biol. Med.* 27, 773-5(1930).—In order to make duplicate detns. on blood from a cut finger the method of Folin and Malmros (cf. *C. A.* 23, 4492) was applied with the following technic: measure 0.02 cc. of blood in a blood pipet and blow it into 2 cc. tungstic acid soln. in a 5 cc. test tube; rinse the pipet, stir for 1 min. and centrifuge. Transfer 1 cc. of the clear fluid to a 5 cc. graduated tube, and 5 cc. of the standard sugar soln. to another 5 cc. tube. Add to each tube 0.4 cc. of $K_4Fe(CN)_6$ soln. and 0.2 cc. of cyanide-carbonate soln. Boil 8 min., cool in running water 1 min., add 1 cc. of ferric iron-ghatti soln., shake and let stand 1 min. Dil. to 5 cc. with H_2O and make 10 colorimetric readings as rapidly as possible. C. V. BAILEY

Vital staining with methyl red. ROBERT CHAMBERS. *Proc. Soc. Exptl. Biol. Med.* 27, 809-11(1930).—Samples of normal sea water p_H 8.4 were brought to a p_H of 5.0 and 6.0 by the addn. of NaH_2PO_4. Several drops of Clark and Lub's standard 0.4% aq. soln. of methyl red were added to the samples and also to normal sea water. Mature starfish eggs were immersed in the various samples for periods up to $^1/_2$ hr. and then washed in sea water of the same p_H. Eggs from samples of p_H 8.4 and p_H 6 were unstained; those in samples of p_H 5.0 were brilliantly and diffusely colored yellow and contained red granules; this color disappeared when the cells were washed in sea water at a p_H above 6. C. V. BAILEY

The determination of the p_H of blood serum with quinhydrone electrode. MARTIN E. HANKE. *Proc. Soc. Exptl. Biol. Med.* 27, 972-3(1930).—The electrode vessel consists of 2 ordinary glass tubes which fit snugly one inside the other, a rubber connection which holds the tubes in any desired relative position, and a Pt wire sealed into the inner tube. The inner tube contains Hg through which metal contact to the Pt wire is made. The outer tube is 8 cm. long with a 4 mm. lumen giving a total capacity of about 1 cc. By moving the inner tube, fluid is drawn up or expelled from the outer tube. In use the vessel is filled to the 0.2 cc. mark with a clear satd. soln. of quinhydrone in boiled neutral distd. H_2O. Then at a time noted with a stopwatch, serum is drawn up to the 0.4 cc. mark, also a bubble of air for rapidly mixing the solns. The vessel is clamped upright in a beaker contg. satd. KCl and the potential is read at 30, 40, 50 and 60 seconds. An illustrative calcn. is given. C. V. BAILEY

The colorimetric determination of phenols in feces. MME. JONCKHEERE-DEBERGH AND R. GOIFFON. *Compt. rend. soc. biol.* 103, 485-7(1930).—The filtrate obtained after the addn. of tungstic acid to a 10% diln. of feces is treated with $ZnCl_2$ and Na_2CO_3; the $ZnCO_3$ retains sulfides which otherwise interfere with the development of a blue color by the Folin-Denis phenol reagent. The av. phenol content of feces (wet wt.) is 40 mg. per 100 g. (25-125). A low phenol content in the feces has been found assocd. with a high NH_3 content, and a large amt. of phenol with an amt. of org. acids indicating a predominance of fermentations. B. C. BRUNSTETTER

The antimony electrode and the hydrogen electrode. M. VERAIN AND MLLE. TOUSSAINT. *Compt. rend. soc. biol.* 103, 611-2(1930).—The Verain design of the H electrode and the Vlès type of Sb electrode were compared on more than 100 detns. of p_H of blood: in 55% of the cases, the difference was 0.02 p_H or less; 23% gave a difference of 0.03 p_H; 11%, a difference of 0.04 p_H, while in 11% of the cases, the difference was from 0.05 to 0.10 p_H. B. C. BRUNSTETTER

Quantitative blood analysis. M. WAGENAAR. *Pharm. Weekblad* 67, 1093-1100 (1930); cf. *C. A.* 24, 3258.—For identification of blood stains on clothing and estn. of the quantity present, application is made of the fact that blood contains N and Fe in the ratio of approx. 60:1. The stained fabric is analyzed for N and Fe, also an equal area of the unstained portion of the same material, for deduction as a blank. If the values so obtained for N and Fe have a ratio of 60:1, the stain in all probability consists

of blood. Each 30 mg. of N and 0.5 mg. Fe corresponds to 1 g. of blood. The great advantage of this procedure is that the result is independent of the condition of the blood stain, whether the sample is old, decompd., faded by sunlight or strongly heated. A. W. Dox

Acetylcholine and choline from animal organs. I. Preparation from beef blood. J. Kapfhammer and C. Bischoff. *Z. physiol. Chem.* 191, 179–82(1930).—Five l. of beef blood was treated with 8 g. of $C_2H_2O_4$, poured into 15 l. of 96% EtOH, and the filtrate concd. *in vacuo* to 150 cc. The soln. was then treated with 20% CCl_3CO_2H, shaken with Et_2O, evapd. again and finally pptd. with 100 cc. of 4% Reinecke acid. The resulting ppt. of acetylcholine reineckate was washed with H_2O, EtOH and Et_2O. The yield was 2.05 g. from 25 l. of blood. The product was converted into the Au salt by dissolving in 50% MeAc, treating the soln. with Ag_2SO_4 and $BaCl_2$ and pptg. the concd. filtrate with $AuCl_3$. Three recrystns. effected a sepn. into the chloroaurates of choline and acetylcholine, the latter being the more difficultly sol. in H_2O. A. W. D.

A new rapid method for the determination of total fatty acids in feces. Erhard Glaser and Oskar Kahler. *Z. physiol. Chem.* **191**, 187–92(1930).—The method consists in boiling 1 g. of the dry, or proportionally more of the moist, feces 0.5 hr. with 5 cc. of 20% aq. KOH, adding 15 cc. EtOH and filtering. This extn. is repeated twice with the residue, and the combined filtrates are evapd. The evapn. residue is dissolved in hot H_2O and transferred to a Gerber butyrometer. This soap soln. is now treated with an equal vol. of concd. H_2SO_4 (10.5 cc.) and 0.05 g. KOCl. After the evolution of gases ceases 1 cc. of AmOH contg. Sudan dye is added and the app. centrifuged. The red fat layer consists of free fatty acids, including those originally present as such and those formed by sapon. of the fat. The butyrometer stem may be calibrated with stearic acid so that 1 scale division is equiv. to 0.01 g. acid or 0.0104 g. of triglyceride. A. W. Dox

A simple Stromuhr (apparatus for measuring rate of blood current). Robert V. Werz. *Arch. exptl. Path. Pharmakol.* **151**, 168–71(1930). H. Eagle

Methods of testing gastric function. III. The frequency and recognition of gall in siphoned gastric contents. L. Dinkin and Z. Lichtig. *Klin. Wochschr.* **9**, 1499–1501(1930); cf. *C. A.* **24**, 5775.—Duodenal regurgitation into the stomach causes pptn., color tints and lowering of surface tension. A yellow tint in the gastric contents indicates recent regurgitation; heavy flocculi indicate an emptying of the gall bladder. A very blue or green discoloration indicates duodenal regurgitation into the stomach occurred several hours before lavage. The absence of discoloration in the Ewald test meal is probably due to adsorption of the gall substances on the particles. The use of dyes in the test meal, or *particulate* matter, is therefore discouraged. H. Eagle

Examination and evaluation of urine in the apothecary shop. Hans Kaiser. *Süddeutsche Apoth. Ztg.* 70, 519–22(1930).—An address. W. O. E.

A new apparatus for determining the coagulation time of blood. Albert Fischer. *Arch. ges. Physiol.* (*Pflügers*) **225**, 737–9(1930). Arthur Grollman

Potentiometric determination of cystine and cysteine. Kageyu Yamazaki. *J. Biochem.* (Japan) **12**, 207–22(1930).—With the potentiometric titration it was found that pure cystine and cysteine solns. can be accurately titrated with $NaBrO_3$ either in the presence or absence of Br^-. In the presence of other amino acids, however, as in a protein hydrolyzate the titration with $NaIO_3$ in the presence of I_2 is more accurate. Temp. and acidity of the soln. play an important role because of the fact that these factors det. the extent to which cysteine is oxidized to cystine or to cysteinic acid, and thus affects the ratio of the 2 products. The rate of titration with the I_2 also exerts some action, more cystine being formed when the oxidation is carried out slowly while more cysteinic acid results in a rapid oxidation. Tryptophan is the only amino acid which influences definitely the titrating value of cysteine by $NaIO_3$, probably because of its own oxidation in the presence of the cysteine. S. Morgulis

The nature of the Gram compound and its bearing on the mechanism of staining. Allen E. Stearn and Esther Wagner Stearn. *J. Bact.* **20**, 287–95(1930).—The cell wall theory of the Gram reaction mechanism in its ordinary form necessitates the existence in the decolorizer soln. of large dye-mordant mols. Absorption spectra indicate the presence of only free I and free dye in solns. of methyl violet-I ppt. in both alc. and acetone. The b. p. elevation of a soln. of this ppt. in acetone indicates complete dissocn. into I and dye. These data do not contradict the chem. mechanism previously proposed by the authors. John T. Myers

Micro method for the determination of highly unsaturated fatty acids (Tangl) 7.

Apparatus for regulating the supply of oxygen for respiration at high altitudes.

JESSE E. ESHBAUGH. U. S. 1,779,840, Oct. 28. Structural features of a device comprising a pressure-reducing valve, etc.

C—BACTERIOLOGY

CHARLES B. MORREY

The lipoids of tubercle bacteria. XVI. The composition of the total extractable fat of tubercle bacteria. R. J. ANDERSON AND ERWIN CHARGAFF. *Z. physiol. Chem.* **191**, 157–65(1930); cf. *C. A.* **24**, 2490.—The total fat capable of extn. by PhMe from tubercle bacteria cultivated on sterile bouillon was sepd. into unsaponifiable wax, carbohydrates, H_2O- and EtOH-sol. cleavage products and fatty acids. The aq. soln. after the sapon. contains glycerol and probably $PrCO_2H$. The fatty acids consist of satd. solid, satd. liquid and unsatd. acids. The unsatd. acids are in part hydrogenated only with difficulty. The satd. liquid fatty acids contain tuberculostearic acid $C_{18}H_{36}O_2$ and phthioic acid $C_{26}H_{52}O_2$. These 2 acids are accompanied in small quantity by a series of liquid satd. acids, one of the higher members having a titration value equiv. to $C_{40}H_{80}O_2$ and sp. rotation in Et_2O of 8.0°. **XVII. The occurrence of an unsaturated hexacosanic acid in the fat of tubercle bacteria.** *Ibid* 166–71.—The difficultly hydrogenated unsatd. fatty acids of the total extractable fat of tubercle bacteria were catalytically hydrogenated and the Me esters of the reduced acids distd. in a high vacuum. The lower fractions consist mainly of stearic acid. A small quantity of palmitic acid may also be present. The highest-boiling fraction contains a *hexacosanic acid* $C_{26}H_{52}O_2$, with m. p. 82–2.5°, which could not be raised by numerous operations. Conclusion: The fat of tubercle bacteria contains an unsatd. hexacosanic acid which, since on hydrogenation it apparently does not yield the hexacosanic acid 88–9°, must have a branched C chain. **XVIII. A polysaccharide from the lipoids of the tubercle bacteria.** ERWIN CHARGAFF AND R. J. ANDERSON. *Ibid* 172–8.—The carbohydrate fraction obtained by sapon. of the crude lipoids with alc. KOH was dissolved in H_2O, pptd. by excess of basic Pb acetate, the ppt. decompd. by H_2S and the filtrate evapd. to a sirup. Addn. of EtOH then pptd. an amorphous yellowish white powder, which decompd. 190° without melting, showed $[\alpha]_D^{23}$ 42.28°, and contained 2.92% ash, mainly phosphate. Hydrolysis by refluxing 2.5 hrs. with 5% H_2SO_4 yielded mannose (identified as phenylhydrazone), *d*-arabinose (identified as benzylphenylhydrazone), *d*-galactose (identified as methylphenylhydrazone), and inositol (isolated as such). The occurrence of *d*-arabinose is noteworthy, since the *l*-isomer is the form usually found in nature.

A. W. DOX

Oxidation-reduction potentials in relation to bacterial growth. I. Oxidation-reduction potential of sterile meat broth. BERT C. J. G. KNIGHT. *Biochem. J.* **24**, 1066–74(1930).—The electrode potentials have been compared with those indicated by Clark's O/R dyes. It is found that the 2 methods do not indicate the same potential level, a dye indicating a more neg. potential than would be shown by an electrode in broth alone. **II. Method of poising the oxidation-reduction potential of bacteriological culture media.** *Ibid* 1075–9.—A method is described whereby the oxidation-reduction potential of bacteriol. culture media can be held const. BENJ. HARROW

A note on the "zone phenomenon" in human sera: a comparison of antitularense with antiabortus sera. R. R. SPENCER. *U. S. Pub. Health Repts.* **45**, 2383–5(1930); cf. *C. A.* **24**, 4334.—In the series of 54 antiabortus sera showing zones, there were 4 showing a middle zone. Not one of the 65 antitularense sera showing a zone produced a middle zone. In the antiabortus series the prezones were usually wider than in the antitularense series. Of the 2000 sera tested, 329 were pos. against *P. tularensis* and 179 were pos. against *A. abortus*. The technic employed is given and results are tabulated.

J. A. KENNEDY

Carbamide-containing culture media. III. ALB. J. J. VANDEVELDE. *Natuurwetenschap. Tijdschr.* **12**, 141–5(1930); cf. *C. A.* **24**, 2488.—Pure cultures of *Bact. lact. acidi*, *Bact. fluorescens* or mixts. of both produced less acid in sterile milk to which carbamide had been added than in milk without this addn. With *Bact. lact. acidi* the reaction finally turned alk. because of the production of NH_3 from the carbamide. *Bact. fluorescens* produced small quantities of lactic acid.

F. DE LEEUW

The appearance of bacteriophage in mixtures of bacteria and pancreas preparations. MARIE THOMAS. *Z. Immunitäts.* **63**, 521–36(1929).—Mixts. of com. pancreas prepns. and bacteria may give rise to bacteriophage when neither the prepn. nor the bacteria alone will develop it. But this method of producing bacteriophage is not const. or certain. Only one prepn. was active with one strain of dysentery bacillus. J. H. L.

Carbohydrate metabolism of the organisms of the genus Mycobacterium. MAL-

COLM H. MERRILL. *J. Bact.* **20**, 235–86(1930).—Detn. of carbohydrate utilization by these organisms, by noting the appearance of acid in the media, is indefinite and impracticable. The reaction curves when *Myco. leprae* and *Myco. phlei* are grown in mannitol broth and *Myco. chelonei* grown in glucose broth are sufficiently characteristic for differentiation but are so profoundly influenced by slight environmental changes that they may lose their value. The reaction changes in plain and carbohydrate broth tend toward progressive increase in alky. This change is less rapid in the presence of utilizable carbohydrates. Detns. of carbohydrates indicate a rather wide utilization. Increase in alky. is assocd. with increase in NH_3, and is usually directly proportional. NH_3 production was distinctly less for a given amt. of growth in the presence of utilizable carbohydrate, and here the reaction change was less. The higher the concn. of carbohydrate, within the limits of growth, the less the increase in NH_3 and the change in reaction. The NH_3 content of the media varied directly as the p_H with each organism. There is no accumulation of carbohydrate cleavage products, the effect on p_H being due wholly to alteration of protein cleavage. This is different from the conditions with other bacteria. There is no inhibition of growth by products of carbohydrate cleavage as with other bacteria. The amt. of CO_2 formed varies directly with the growth of the organisms in both carbohydrate-contg. and carbohydrate-free media, and was much more than that possible from the carbohydrate disappearing. Much more was formed per mg. of NH_3 in the presence of utilizable carbohydrate. Removal of CO_2 from the atm. did not inhibit growth appreciably. The organisms could not be grown anaerobically. If the carbohydrate mol. is attacked it is completely oxidized to CO_2 and H_2O without the accumulation of demonstrable intermediate products. JOHN T. MYERS

Rennin production by Bacillus prodigiosus (Serratia marcescens). G. CORINI. *J. Bact.* **20**, 297–8(1930).—The rennin which is produced differs from calf rennin in that it acts on heated, even autoclaved, milk, and in being highly thermostable since it can be destroyed at 100° only if heated for more than 15 min. JOHN T. MYERS

The use of the Schardinger reaction for the differential diagnosis of B. pestis and B. pseudotuberculosis rod. Pfeifferi. N. IVANOVSKII AND T. SASSYKINA. *Zentr. Bakt. Parasitenk.*, 1 Abt., **117**, 535–9(1930).—Both organisms reduced methylene blue (Schardinger reaction), but the reaction is weaker with *B. pestis*. The quant. reaction will differentiate between the organisms. JOHN T. MYERS

Differential staining of dead and living bacilli. FRIEDRICH WILHELM BICKERT. *Zentr. Bakt. Parasitenk.*, 1 Abt., **117**, 548–51(1930). JOHN T. MYERS

The growth-promoting action of hydrogen sulfide on diphtheria bacilli. FRIEDRICH A. LENTZE. *Zentr. Bakt. Parasitenk.*, 1 Abt., **118**, 51–9(1930).—Diphtheria bacilli in mixed cultures produced larger colonies and had better metachromatic granules than when in pure culture. These organisms produced volatile org. compds. such as amines and in particular H_2S, the latter in concns. of 1:100,000 to 1:10,000. These concns. of H_2S produced the same results as in mixed cultures. H_2S does not act as a foodstuff but stimulates bacterial metabolism. It has a very slight similar effect on pseudo-diphtheria bacilli. JOHN T. MYERS

The growth of paratyphoid-like organisms on synthetic culture media. KARL L. PESCH AND FRIEDRICH-ELIZABETY KOCH. *Zentr. Bakt. Parasitenk.*, 1 Abt., **118**, 129–36(1930). JOHN T. MYERS

The carbon metabolism of the Shiga-Kruse dysentery bacillus. F. W. WIEHMANN. *Zentr. Bakt. Parasitenk.*, 1 Abt., **118**, 150–2(1930).—C can be assimilated from only a small no. of compds. JOHN T. MYERS

A study of the bactericidal action of ultra-violet light. III. The absorption of ultra-violet light by bacteria. FREDERICK L. GATES. *J. Gen. Physiol.* **14**, 31–42 (1930); cf. *C. A.* **24**, 2490.—The conclusion of previous investigators that the shorter the wave length of ultra-violet light the greater the bactericidal action is erroneous. Max. bactericidal efficiency is reached between 260 and 270 mμ. The reciprocal of this abiotic energy curve suggests sp. light absorption by a single essential substance in the cell. This substance is probably not uniformly distributed throughout the cell protoplasm. Methods are described for detg. the absorption curve of intact bacterial cells, and curves for *Staphylococcus aureus* and *Escherichia coli* are given. Further work is in progress. C. H. RICHARDSON

Killing of colon bacilli by x-rays of different wave lengths. RALPH W. G. WYCKOFF. *J. Exptl. Med.* **52**, 769–80(1930); cf. *C. A.* **24**, 5789.—X-ray beams of wave lengths lying in the range between 4 and 0.5 A kill *E. coli* in a semilogarithmically linear fashion; that is, 1 absorption of any of these radiations is sufficient to kill. Though death results from a single absorption, only about 1 hit in 4 with Ag K and 1 in 60 with Ag L radiation

is deadly. The course of curves constructed from these expts. suggests that the portion of the bacterium which is essential to its continued life has a total approx. 0.01 of the cell vol. For Cu and harder radiations the biol. action of the rays is proportional to their measured air ionization. The same biol. change with the softer Cr K and Ag L x-rays seem to require a somewhat more intensely ionizing beam. C. J. WEST

Formation of CH_4 from CO and H by bacteria (LIESKE, HOFMANN) **21.** Sugar solutions derived from peat [used for cultivation of microörganisms] (Brit. pat. 332,235) **18.**

D—BOTANY

THOMAS G. PHILLIPS

The iodide-splitting capacity of the Phaeophyceae. HARALD KYLIN. *Z. physiol. Chem.* **191**, 200–10(1930).—The I volatilization by marine algae, reported by other investigators, was studied more in detail with *Laminaria digitata* collected off the west coast of Sweden. If the exptl. conditions are planned so as to duplicate as closely as possible the natural conditions, such volatilization of I cannot be demonstrated. However, under certain conditions, *e. g.*, treatment of the leaf surface with distd. H_2O, it is possible to detect I volatilization. Only the living thallus parts have this property, and immediately after death of the organism it disappears. The necessary factors for the reaction are iodides, iodide-oxidases and O. In the *Laminaria* species both iodides and their oxidases are present and as soon as these factors are brought together under favorable conditions, free I is liberated. Both of these factors occur in the superficial cells, but only when the iodides pass out into the outer wall does the reaction occur. The free I is therefore formed in the outer wall of living superficial cells. The enzyme is thermolabile and is inactivated by heating 1 min. on a boiling water bath. A dried prepn. obtained from surface scrapings retains its activity after 10 min. contact with concd. AcOH, or 5 min. contact with 5% HCl or H_2SO_4. The problem of I volatilization is in reality a question of permeability. Among the factors which accelerate the reaction are small doses of Et_2O or $CHCl_3$, a faintly acid reaction and distd. H_2O. These factors facilitate the release of iodides, but at the same time kill the organism more or less rapidly. The diffusion is influenced also by the natural variations, between 2.5 and 3.0%, of the salt content of sea water. The lower concn. causes a diffusion of the salt constituents of the surface cells into the outer membrane where the liberation of I occurs.
A. W. Dox

Biochemistry of the smut diseases of cereals. III. The copper adsorption of the spores of loose smut of oats (Ustilago avenae (Pers.) Jens). ALEXANDER TERENYI. *Z. physiol. Chem.* **192**, 274–80(1930); cf. *C. A* **24**, 1883.—The spores of oat smut adsorb 1.2–50% more Cu from $CuSO_4$, $Cu(OAc)_2$ and $Cu(NH_3)_4SO_4$ solns. than those of wheat smut. The Freundlich formula: $x = R(C - x)^n$ is valid here also. These spores are much less sensitive to the Cu adsorbed in the spore walls, since 3% of adsorbed Cu is required to inhibit germination, as contrasted with 0.5% for the wheat smut spores. After 15 min. treatment with the Cu solns. the germinating power of the spores can be restored by HCl; in this respect their behavior is the same as that of the wheat smut. Unlike the wheat spores, however, they do not regain their germinating power after a 24 hr. treatment with Cu followed by HCl, indicating that the adsorbed Cu has penetrated into the inner layers. Treatment with $Cu(NH_3)_4SO_4$ destroys both kinds of spores.
A. W. Dox

Light and the plant. JOH. RICHTER. *Pharm. Zentr.* **71**, 545–9(1930).—A discussion of the various factors affecting plants most profoundly in the presence and absence of light, notably in the production of chlorophyll. W. O. E.

Some aspects of the chemistry of green leaf cells. HUBERT B. VICKERY. *Sci. Monthly*, Nov. 1930, 408–21. E. H.

Chemical examination of the seeds of Cassia tora, Linn. I. H. SUBBA JOIS AND B. L. MANJUNATH. *J. Indian Chem. Soc.* **7**, 521–6(1930).—The leaves, seeds, roots and stems of the shrub *Cassia tora* are used in medicines. The seeds have previously been shown to contain a glucoside of a substance that resembles emodin, to which the medicinal properties have been ascribed. In a petr. ether ext. of the seeds the following compds. have been found: oleic, linoleic, palmitic and lignoceric acids, and sitosterol. A further study is being made. AMY LEVESCONTE

Some notes on lavender. ÉTABLISSEMENTS ANTOINE CHIRIS. *Parfums de France* **8**, 227–40(1930).—In French and English. The general botanical characteristics of lavender, its morphological and biol. variations and general considerations on its cultivation, harvesting and treatment are given. The superiority of lavender concrete over the distd. oil is brought out. A. PAPINEAU-COUTURE

Studies on penetration of dyes with glass electrode. IV. Penetration of brilliant cresyl blue into Nitella flexilis. MARIAN IRWIN. *J. Gen. Physiol.* **14**, 1–17(1930); cf. *C. A.* **21**, 1131.—Studies on the p_H value of the sap of *N. flexilis* by means of the glass electrode show that brilliant cresyl blue penetrates the vacuoles in the form of free base and upon gaining contact with the sap is at once partly converted to dye salt. The resulting increase in p_H value of the sap is due to the presence of the dye and not to some other alk. substance When the cell protoplasm is squeezed into the sap the p_H of the mixt. is higher than that of pure sap but the behavior of the mixt. in respect to the dye is similar. **V. Why does azure B penetrate more readily than methylene blue or crystal violet?** *Ibid* 19–29.—Further expts. show that azure B penetrates the vacuoles of *N. flexilis* chiefly as free base. Crystal violet exists only in one form between p_H 5 and 9.2. It does not alter the p_H of the sap at the concns. used. With azure B and methylene blue the rise in p_H of a mixt. of sap and protoplasm is not so pronounced as with sap when the dye penetrates into the vacuoles. The behavior of living cells to these dyes is explained by a theory of "multiple partition coeffs." previously described. Cf. *C. A.* **22**, 1612, 4580; **23**, 4243. C. H. RICHARDSON

The accumulation of electrolytes. I. The entrance of ammonia into Valonia macrophysa. WM. C. COOPER, JR. AND W. J. V. OSTERHOUT. *J. Gen. Physiol.* **14**, 117–25(1930).—NH_4Cl in sea water enters cells of *Valonia* reaching a concn. in the sap of over 40 times that in the sea water. It seems to enter as undissocd. NH_3 or NH_4OH reaching a pseudoequil. in which activity of undissocd. NH_3 (or NH_4OH) is the same inside and outside. When it first enters the cell the p_H of the sap rapidly increases but soon reaches a max. and then declines. There is a simultaneous increase in halide in the sap which does not parallel the NH_3 accumulation but reaches an equil. and remains const. The increase in NH_3 content of the sap is accompanied by a decrease in K concn. The entrance of NH_3 decreases the sp. gr. of the sap so that the cells rise to the surface and grow as floating organisms. The growth of these cells is increased. C. H. R.

The influence of copper sulfate on the growth of Piricularia oryzae, with special reference to the temperature as an environmental factor. T. ABE. *Ann. Phytopath. Soc. Japan* **2**, 171–96(1930); *Rev. Applied Mycol.* **9**, 555.—Addn. of Cu sulfate in concns. of $^1/_{400}$ to $^1/_{6,000}$ mol. to the agar medium of *Piricularia oryzae* stimulated development of the fungus at 28°. The optimum temp. for mycelial growth in this strain is 28° and at temps. of 20, 24, 32 and 36° the stimulatory action of Cu sulfate was not apparent. Conidial formation was retarded at all temps. in inverse ratio to the amt. of Cu sulfate at concns. above $^1/_{6,000}$ mol., under which conditions chlamydospores were formed at all the temps. tested, while the color of the colonies underwent striking changes. O. E. SHEPPARD

Chlorophyll deficiency. H. v. EULER AND O. MORITZ. *Arkiv. Kemi, Mineral. Geol.* **10A**, No. 11, 1–15(1930); cf. *C. A.* **23**, 3483, 5213; **24**, 1134, 3534.—Although albino cotyledons of barley show only $^2/_5$ as much catalase as the normal there is no difference in activity between the yellow mutant of Nilsson-Ehle and the normal. In the pumpkin the catalase activity parallels the ability of the etiolated cotyledons to become green. There is no parallelism, however, between the chlorophyll content of green leaves and their catalase activity. J. J. WILLAMAN

The variation of electrical resistance with applied potential. III. Impaled *Valonia ventricosa* (BLINKS) **2.** Dark field microscopy with polygonal illumination (SPIERER) **2.** The oil-bearing Royal Palm tree seed of the West Indies (HEIM DE BALSAC, *et al.*) **27.**

E—NUTRITION

PHILIP B. HAWK

Vitamin D and the antirachitic activation of foods by irradiation with ultra-violet light. F. L. GUNDERSON. *Cereal Chemistry* **7**, 449–55(1930).—Rickets is believed to occur to the extent of 70 to 90% of the infant population and together with dental caries constitutes one of the most widely occurring phys. imperfections of mankind. This situation is in large part due to the limited consumption of vitamin D, which condition is caused by its limited occurrence in natural foods. Most foods can be antirachitically activated by exposure to ultra-violet light such as that of a Hg vapor or C arc lamp. Potency thus imparted is believed to be due to an intramol. rearrangement in the ergosterol mol. Antirachitic potency of irradiated foods is highly stable to ordinary storage and household cooking but is subject to destruction at some of the higher temps. combined with certain other variable factors existent in com. baking. The exact degree of stability cannot be predicted; it must be detd. With rigid biol.

control to insure a desirable and definitely known degree of antirachitic activation the irradiation of foods has large possibilities for improving the human diet. L. H. B.

Cereals and mineral metabolism. M. S. FINE. *Cereal Chemistry* **7**, 456–65 (1930).—Rats were fed for long periods on diets contg. 60% whole wheat, and 60% oats with suitable variations in the Ca:P ratios in 2 series. By means of x-ray examns. progressive bone changes were observed. It is concluded that occurrence or non-occurrence of rickets on both these grain diets can be controlled by proper adjustment of the Ca:P ratio within wide limits of consumption levels of these elements. Evidence of spontaneous cures on rachitogenic wheat diets is presented. With a comparable oat diet there is less tendency toward such spontaneous cure. Growth and food consumption were better on the wheat than on corresponding oat diets. These differences are in harmony with data reported by Mellanby, by Steenbock, Black and Thomas and by Burton. L. H. BAILEY

Glycogen formation in rats. III. Diets containing 87.5 per cent of total calorific value in lactose, glucose and sucrose. ESTHER M. GREISHEIMER AND OLGA H. JOHNSON. *Proc. Soc. Exptl. Biol. Med.* **27**, 769–70(1930).—The rats fed on the lactose diet developed diarrhea and ate less than rats on the other diets. The feeding periods varied from 16 to 18 days. The liver glycogen averaged 3.15 ± 12% on the lactose diet, 4.89 ± 0.21% on the glucose, and 4.89 ± 0.2% on the sucrose. If lactose were as easily digested and absorbed as the other sugars, glycogen would be as readily formed from lactose as from glucose or sucrose. **IV. Diet containing 87.5 per cent of total calorific value in maltose.** *Ibid* 770–1.—The liver glycogen formed on the maltose diet was considerably higher than that formed on the control diet. C. V. BAILEY

Increased resistance of rachitic rats fed irradiated food. ELIZABETH CHANT ROBERTSON AND JOHN R. ROSS. *Proc. Soc. Exptl. Biol. Med.* **27**, 999–1002(1930).—Of 89 rats fed a rachitic diet including nonirradiated whole wheat, 5% survived a *per os* enteriditis infection, as compared with 30% survival of 94 rats fed a similar diet including irradiated whole wheat. C. V. BAILEY

The development and growth of dogs raised with an artificial milk containing visceral proteins. MAURICE RENAUD. *Compt. rend. soc. biol.* **103**, 232–4(1930).—The following ration gave excellent growth of young puppies over a period of 7 to 60 days; milk serum, 1000; cream, 40; casein, 20; milk albumin, 10; beef tissue (liver, spleen, brain, blood), 30; and to guard against vitamin deficiency, fruit juice and yeast. The vigor was fully as good as that of controls fed on the mother milk. B. C. BRUNSTETTER

The effect of irradiated ergosterol on the white corpuscles of rabbit blood. A. C. FRASER *Compt. rend. soc. biol.* **103**, 461–2(1930).—Toxic doses of irradiated ergosterol (15–25 mg. per kg.) given daily to the rabbit *per os* cause a decrease in the no. of lymphocytes in the blood, and an increase in the no. of neutrophile polynuclears and of monocytes. B. C. BRUNSTETTER

Further experiments on irradiated ergosterol. A. WINDAUS. *Nachr. Ges. Wiss. Göttingen Math.-physik. Klasse* **1930**, No. 1, 36–57(1930); cf. *C. A.* **24**, 4518.—Vitamin D was found to be a low-melting oil, having a slight neg. rotation and an absorption band at 270 A. U. It is stable in soy oil but decomps. slowly *in vacuo* without solvent. It is rapidly decompd. by heating at 150°, by excessive irradiation, by O_2, or by treatment with NaOEt. In the last case a dihydro alc. originates which may amount to 50% of vitamin prepn. This compd. has no absorption bands above 240 A. U. The prepns. of vitamin D also contain a toxic substance which is probably distinct from the antirachitic factor although the prepns. most active in curing rickets are at the same time most toxic. The toxic compd. has no absorption band above 260 A. U. but has a characteristic one at 247. A compd. with absorption bands at 280–290 A. U. and a cryst. alc. having no lines above 240, both of which are strongly dextro-rotatory, also originate from vitamin D. H. J. DEUEL, JR.

Investigations on irradiated ergosterol. ADOLPH WINDAUS. *Nachr. Ges. Wiss. Göttingen Geschäft Mitt.* **12**, 47–53(1929–30).—A report of earlier work. H. J. D., JR.

The group of water-soluble vitamins and their relationship to each other. II. The significance of alkaline heamatin, age of rats, and the composition of diet in vitamin-B deficiency. W. KOLLATH. *Arch. exptl. Path. Pharmakol.* **150**, 236–55(1930); cf. *C. A.* **24**, 1887.—Alk. hematin, and apparently also deuterohemin, added to a vitamin-poor diet which usually initiates a scurvy-like disease, cause 76% of young rats to develop beriberi, as compared to a normal incidence of 10%. Older rats have a much greater spontaneous incidence of beriberi (54.5%) on this same diet. Iron salts do not have this effect. Casein, extd. with 96% alc. or 1% HCl, does not affect this hematin-induced beriberi. It is suggested that the importance of hematin as a food factor is that it causes anaerobiosis in the intestine by catalyzing the oxidation of unsatd. fatty

acids. It is noteworthy that a buffered enzyme mixt. added to a vitamin-poor diet doubled the life of the animals, and that no characteristic disease syndrome developed.
H. EAGLE

Comparative value of different kinds of molasses in lamb-fattening rations. GEO. E. MORTON. *Colo. Agr. Expt. Sta., Report for 1929*, 16(1930).—Lamb-feeding expts. have indicated a higher value for beet molasses than for cane molasses when proper care is exercised in gradually introducing the beet molasses into the ration. With the new Ba process for extg. addnl. sugar from Steffens discard molasses, a new final discard molasses is produced. This molasses contains a higher % of carbohydrates than the Steffens molasses but more of the sugar is raffinose. The tests are being continued.
C. R. FELLERS

Observations on a diatom (Nitzschia closterium W. SM) as a source of vitamin A. BASHIR AHMAD. *Biochem. J.* **24**, 860–5(1930).—*Nitzschia* and the oil obtained from it are good sources of vitamin A. The extd. oil gives a pos. reaction with $SbCl_3$. Carotene is probably responsible for the greater part of the biological activity of the oil.
BENJAMIN HARROW

Vitamin A of butter. RICHARD A. MORTON AND ISIDOR M. HEILBRON. *Biochem. J.* **24**, 870–3(1930).—Non-saponified fraction from butter contains carotene, vitamin A, and an unidentified substance (selective absorption at 272$\mu\mu$). BENJAMIN HARROW

Carotene and vitamin A. The transformation of carotene into vitamin A as shown by a study of the absorption spectra of rat-liver oils. NORMAN S. CAPPER. *Biochem. J.* **24**, 980–2(1930).—The liver oil of rats suffering from vitamin A deficiency shows no absorption band at 325$\mu\mu$; but the liver oil of similar rats which had been cured by addn. of carotene to the diet did show this absorption band. The band at 325$\mu\mu$ is attributed to vitamin A. Carotene does not show this band. Vitamin A has therefore been synthesized *in vivo* from carotene. BENJAMIN HARROW

Effects of cystine diet on keratin composition in rabbit wool. JOHN BARRITT, ALBERT T. KING AND JAMES NICHOL PICKARD. *Biochem. J.* **24**, 1061–5(1930).—No differences in S content in fur were found between the control rabbits and those fed on the cystine-rich diet. BENJAMIN HARROW

The chemical constitution of the carotenoid pigments and the relation of carotene to vitamin A. A review. JOHN M. GULLAND. *Chemistry and Industry* **49**, 839–47 (1930). E. H.

A new basis for evaluating the calcium and phosphorus content of diets. JOSEF SCHNEIDER. *Chem. Listy* **24**, 181–5(1930).—If a normal human body receives Ca and P in the same ratio in which it deposits these 2 elements in its ash depots which for bone is Ca:P::1:0.444, and if the quantity of Ca taken in during a 24-hr. period lies between 1 and 1.33 g., no vitamin D or radiation of the body or food is necessary. Foods in which this ratio is approached are: lemons, oranges, celery, cauliflower, cabbage, milk, turnips, cheeses, cream and carrots. The Ca:P ratio here ranges from 1:0.417 to 1:0.821. Diets may also include bone in which the Ca:P ratio is very favorable for absorption. Certain races (Tartars, Arabs) base their diet upon milk and its products without involving vitamin D; the Ca:P ratio is close to that of the body and no disturbance is encountered. Only in diets in which the Ca:P ratio becomes 1:1.06 or 1:1.4, etc., does the vitamin begin to function. FRANK MARESH

The significance of bile acids in the carbohydrate metabolism. VIII. The mechanism of the hypoglucemic action of bile acids. KANEJI TSUJI. *J. Biochem.* (Japan) **12**, 139–60(1930).—Administration of bile acids lowers the fasting blood-sugar concn. in rabbits. This hypoglucemic effect can be prevented by sectioning the splanchnics, which leads to the conclusion that the bile acids paralyze the sympathetic. Similarly, the antagonistic effect of the bile acids on the adrenaline hyperglucemia is prevented by splanchnectomy. Long after this operation adrenaline glucosuria fails to appear with or without administration of bile acids, because of the lowering of the threshold for sugar excretion. Following the sectioning of the vagus nerve small doses of bile acid have either no influence or actually lower the hypoglucemic action, whereas large doses increase it. Since this hypoglucemic effect can be increased also by K ions, it is concluded that the bile acids stimulate the parasympathetic. The bile acids inhibit the nerve impulses from the sugar center in the medulla oblongata. The bile acids then exert their action through the autonomic nerves either by direct action on the liver or indirectly through the effect on the adrenals, and aid in regulating the carbohydrate metabolism by inhibiting the mobilization of glycogen and promoting its formation in the liver and muscles. S. MORGULIS

Further observations on the relation of carotene to vitamin A. J. C. DRUMMOND, B. AHMAD AND R. A. MORTON. *J. Soc. Chem. Ind.* **49**, 291–6T(1930).—Carotene, in

doses as low as 0.005 mg., promotes growth in rats depleted of vitamin A. Previous failure to demonstrate this was due to the use as a vehicle of purified Et oleate whose oxidation affected the carotene. Paraffin oil, hydrogenated cottonseed oil, and Et laurate are stable vehicles and the latter is recommended. The vitamin A of plant foodstuffs is probably carotene. Growth tests with liver fat from rats fed carotene indicate that the latter is converted into vitamin A which is probably a colorless substance, since the activity of the fat is greater than that indicated by its yellow color. The growth-promoting activity, however, was much less than was expected from its chromogenic value ($SbCl_3$). Future methods for the assay of vitamin A will probably be spectrometric. A sample of palm oil was a rich source of vitamin A. Dihydro-α-crocetin which produces a blue color with $SbCl_3$ cannot replace vitamin A in the diet.

BERNARD L. OSER

The toxic effects of irradiated ergosterol. J. C. HOYLE. *J. Pharmacol.* **38**, 271–89 (1930).—Rats on a synthetic diet fed large amts. of irradiated ergosterol show marked loss in wt., and deposits of Ca in walls of blood vessels, kidneys and heart muscle. When the animals are on a bread and milk diet, these toxic effects are absent, although there is a slight loss in wt.

C. RIEGEL

The importance of magnesium in human nutrition, and its influence in the formation of cancers. CARLO MARCHI. *L'Alimentazione* **1**, 8–14(1930).—See *C. A.* **24**, 5062.

R. SANSONE

Morphological changes of the fore-stomach of the mouse due to feeding upon specific diets. TOKUJI HIRATA. *Sei-i-kwai Med. J.* **49**, No. 4, 1–26 (English abstract 1–6)(1930).—The effect of 13 different combinations of the diet having deficient vitamin A upon the fore-stomach of mice was analyzed morphologically. Hyperkeratosis was observed, although in a lesser degree than in the albino rat.

S. TASHIRO

Degradation acid of ergosterol (REINDEL, NIEDERLÄNDER) 10.

G—PATHOLOGY

H. GIDEON WELLS

Identity of animal anaphylaxis and human allergy (protein hypersensitiveness). BRET RATNER AND HELEN LEE GRUEHL. *Proc. Soc. Exptl. Biol. Med.* **27**, 574–6(1920).—The blood of a human asthmatic and the blood of an asthmatic guinea pig can passively sensitize the normal human skin and normal guinea pigs. Hypersensitiveness in man and anaphylaxis in the lower animal are fundamentally dependent on a common anaphylactic antibody.

C. V. B.

Insusceptibility of the albino rat to experimental amyloidosis. B. L. ROBINSON AND H. S. THATCHER. *Proc. Soc. Exptl. Biol. Med.* **27**, 580–2(1930).—Nitrose injection produced amyloid in 46.6% of mice; it was ineffective in adrenalectomized rats and even in cases where infection was present.

C. V. BAILEY

Further observations on hemagglutination by tumor extracts. K. LANDSTEINER. *Proc. Soc. Exptl. Biol. Med.* **27**, 813–4(1930).—Six g. of rat sarcoma was ground with 5 cc. H_2O and poured into 25 cc. of boiling water slightly acidified with 3 drops of 5% AcOH. The suspension was heated to boiling, cooled, centrifuged and the supernatant fluid neutralized and evapd. to dryness by a special technic which avoids oxidation. The dry material was dissolved in 5 cc. saline soln. contg. 0.2% cysteine This soln. had a stronger activity than the original tumor ext.; it agglutinated rabbit blood instantly and in contrast to the original ext. it agglutinated also the blood of sheep, horse and guinea pig.

C. V. BAILEY

Observations on intestinal obstruction following the intravenous injection of particulate material. OWEN H. WANGENSTEEN AND H. HAMILTON COOKE. *Proc. Soc. Exptl. Biol. Med.* **27**, 957–8(1930).—The reticuloendothelial system of the rabbit was partially blocked in its phagocytic activity by daily intravenous injections of a colloidal prepn. of graphite; in such rabbits the time of survival, following complete intestinal obstruction 10 cm. from the ileocecal valve, was definitely shortened. C. V. B.

Influence of the medium on malignant cell division. R. REDING AND A. SLOSSE. *Ann. bull. soc. roy. sci. med. nat., Bruxelles* 1929, 232–59.—A review of Reading's theory of the origin of cancer as due to an alkalosis of tissue fluids. *Alkalosis*, resulting in lowering of blood Ca, and assocd. with glucemia, creates a medium favorable to rapid cell division and leads to malignancy. Alkalosis is found to precede the onset of cancer; it diminishes following any temporary improvement brought about by irradiation, operation or parathyroid hormone, and reappears following relapse. Relatives of cancer patients or patients predisposed to cancer exhibit a moderate alkalosis.

R. BEUTNER

The origin and nature of antitoxins and antibodies in general. G. RAMON. *Japan Med. World* 10, 66–74(1930).—The antitoxins and antibodies in general find their origin in the formation of humoral complexes formed from substances furnished by the organism and from elements derived from the sp. antigen by physicochem. or simpler phys. processes carried out in the medium of the blood. RACHEL BROWN

Cobra venom, rendered inactive by the action of ultra-violet light, has lost its immunizing power. ANDRÉ ARTHUS. *Compt. rend. soc. biol.* 103, 130–2(1930).—A soln. of cobra venom (2 mg. dry residue per cc.) in 1% saline soln. was mixed with an equal vol. of 2% gelatin soln. The addn. of gelatin prevents the flocculation of the venom which otherwise occurs several hrs. after exposure to ultra-violet light. Irradiation was given for 2 hrs. at a distance of 60 cm. The effect of the treatment was to destroy both the toxicity and the antigenic power of the cobra venom. B. C. BRUNSTETTER

Investigations of intertissue p_H in diabetes insipidus. G. MARINESCO, O. SAGER AND E. SORU. *Compt. rend. soc. biol.* 103, 171–2(1930).—The tissue p_H of 4 normal subjects was 7.12–7.14; the tissue p_H of 4 cases of diabetes insipidus was 6.95, 7.02, 7.03 and 6.67. The appearance of a very acid tissue p_H is a sign of cachexia and is due to acid substances resulting from an abnormal metabolism. B. C. BRUNSTETTER

Blood phosphorus, inorganic and lipoidal, in hyperthyroidism. C. I. PARHON AND M. CAHANE. *Compt. rend. soc. biol.* 103, 284–5(1930).—The results obtained by feeding dried thyroid gland to 5 rabbits and 2 dogs indicate after comparison with analyses on control animals that hyperthyroidism tends to increase inorg. P and to decrease lipoidal P. B. C. BRUNSTETTER

The blood sulfur in hyperthyroidism. C. I. PARHON AND M. CAHANE. *Compt. rend. soc. biol.* 103, 191–2(1930).—Dried thyroid gland (2–12 g. per day) was fed to 6 dogs over a period of 21–38 days, resulting in a loss of weight of 1.3–3.9 kg. The av. total S in the blood before treatment was 0.085 g. per 1000 (0.052–0.118); after treatment, the av. was 0.056 g. per 1000 (0.038–0.075). Two rabbits were given 0.3 g. of dried thyroid per day for 12 days: the total blood S before treatment was 0.046 and 0.056 g. per 1000; after treatment, it was 0.054 and 0.073 g. per 1000. B. C. B.

The effect of magnesium hyposulfite on serological flocculation reactions. E. TECHONEYRES AND MLLE. S. PILLEMENT. *Compt. rend. soc. biol.* 103, 674–5(1930).—The addn. of 0.4 cc. of $N/1$ MgS_2O_3 to 0.8 cc. of serum suppresses or considerably diminishes the flocculating action of perethynol. Lumiere's observation that alk. hyposulfites tend to dissolve colloidal ppts. is quantitatively confirmed. B. C. BRUNSTETTER

The anatomical localization of uremia in the experimental renal insufficiency of the dog. M. FRANKE. *Compt. rend. soc. biol.* 102, 1086–8(1929); cf. *C. A.* 22, 3220.—Previous work is summarized and extended. Exptl. renal insufficiency in dogs was produced by the injection of $HgCl_2$ and of $UO_2(NO_3)_2$. Confirming previous conclusions, the increased concn. of residual N in the blood is paralleled by lesions of the epithelia of the renal tubules; the renal glomeruli are intact. B. C. BRUNSTETTER

Phosphatide deposition in the spleen cells in Niemann-Pick disease compared with the lipoid chemistry of Gaucher disease and of Schüller-Christian disease. EMIL EPSTEIN AND KARL LORENZ. *Z. physiol. Chem.* 192, 145–70(1930).—The 3 main types of general lipoidoses, the Niemann-Pick, the Gaucher and the Schüller-Christian diseases are characterized by very definite chem. findings. The term "general lipoidoses" taken in its broadest sense includes all those disease conditions in which there have developed extensive deposits of lipoids in various organs, or lipoid deposits in organs and cells which form a functionally interdependent system. In all lipoidoses the substances deposited consist of complex lipoid-fat mixts. Each type, however, is characterized by the predominance of a definite lipoid. Four types may be distinguished: (1) phosphatide lipoidosis of the Niemann-Pick type, by the Et_2O-sol. lecithin and presumably also by hitherto undifferentiated Et_2O-insol. but EtOH-sol. phosphatides; (2) cerebroside lipoidosis (hepatosplenomegaly) of the Gaucher type, by the cerebroside kerasin, in individual cases possibly also by a related cerebroside; (3) cholesterol lipoidosis of the Schüller-Christian type, by cholesterol and its esters; (4) cholesterol xanthomatoses of skin, mucosae and internal organs, assocd. with diabetes or icterus, and not included in the preceding groups. The chemistry and phys. chemistry of the lipoids characterizing the individual disease types, especially in their influence on the colloidal dispersion of the lipoids concerned, are of the utmost importance in detg. the symptoms and prognosis of the disease. The application of lipoid chemistry has done much to elucidate the pathology of general lipoidoses but the greatest problems of chemism and origin still await solution. A. W. DOX

The chemistry of hypertrophy and atrophy of muscles. I. Tension and relaxation of skeletal muscles. H. WASSERMEYER AND A. ROHRBACH. *Arch. exptl. Path. Pharma-*

kol. **150**, 133–45(1930).—Rabbit muscles (quadriceps and sartorius) kept under moderate tension for days show moderate hypertrophy, accompanied by delayed postmortem vigor, better function, no increase in glycogen, or in postmortem splitting off of NH_3. In atrophy caused by keeping the muscle under maximal tension there is accelerated splitting off of NH_3: in atrophy caused by keeping the muscle relaxed there is no sudden formation of NH_3, but an appreciably increased glycogen, decreased lactic acid and accelerated appearance of rigor. These results indicate that there is some qual. difference in the muscular hypertrophy caused by tension and by exercise. The change in glycogen:lactic acid ratio in relaxation atrophy is possibly due to decreased tonus.
H. EAGLE

The permeability of red cells for chloride ion in diabetes. KONRAD LANG. *Arch. exptl. Path. Pharmakol.* **152**, 168–76(1930).—Increased CO_2 tension in blood usually causes Cl^- to move from the plasma to the red cells. In diabetics, the amt. transferred is only $^1/_2$ the normal amt., possibly because of decreased permeability of the erythrocytes. Following insulin, the degree of Cl shift increases, presumably because of return of permeability toward the normal value. No analogous sugar migration could be demonstrated.
H. EAGLE

The iron content of the organs in icterus. HANS HORSTERS. *Arch. exptl. Path. Pharmakol.* **152**, 198–209(1930).—The normal Fe content of the skin is 10.5 mg./1000 g., increased 100% and more in cases of icterus with a pos. intracutaneous blue test (*i. e.*, blue color in a postmortem $K_3Fe(CN)_6$ skin wheal). Splenic and hepatic Fe content also increase; the proportion of bivalent Fe in the liver is sometimes strikingly increased. Gall bladder bile of such icteric subjects contains 6.1–9.5 mg. % of Fe. The jaundice is due to toxic injury to liver parenchyma. In contrast, the cases with obstructive jaundice and a neg. blue test usually show a lowered Fe content in the skin (5.8 mg. % instead of 10.5), a low proportion of Fe^{++} to Fe^{+++} in the liver, and as high as 17 mg. % of Fe in gall bladder bile. Cases of aplastic anemia show a high proportion of Fe^{++} in the liver and spleen, indicative of marked blood destruction. Skin Fe is highest in the fetus (45 mg. %), yet the $K_3Fe(CN)_6$ test is either neg. or weakly pos., indicating Fe^{+++}.
H. EAGLE

Influencing the sugar metabolism by operative procedures. I. The sectioning of the vegetative nerves in the ligamentum hepatoduodenale in the normal dog. F. DEPISCH, R. HASENÖHRL AND L. SCHÖNBAUER. *Klin. Wochschr.* **9**, 1437–43(1930).—The mild disturbance of sugar metabolism caused by partial extirpation of the pancreas can be partially (in one case completely) cured by sectioning the nerves; there is, however, no effect upon the severe diabetes caused by subtotal pancreatectomy. Periarterial sympathectomy of the vessels of all 4 extremities also causes an improvement in mild cases, possibly because of a neurogenic effect upon sugar content in tissues.
H. EAGLE

Experiments in the demonstration of a carcinolysin in the blood serum of cancerous patients. HERMANN LEHMANN-FACIUS. *Klin. Wochschr.* **9**, 1504 (1930).—Heated carcinoma cells are lysed by the serum of cancerous individuals, apparently because of a reaction with alc.-sol. components of the carcinoma cells.
H. EAGLE

Note on the possible mechanism of diphtheria toxoid formation. LESLIE F. HEWITT. *Biochem. J.* **24**, 983–92(1930).—When diphtheria toxin is incubated with CH_2O, the toxic properties disappear, leaving the antigenic function practically unimpaired. Of the amino N present in fresh diphtheria toxins some 85% remains free in completely detoxified toxoids prepd. by incubation with CH_2O. Maintenance of toxins under reducing or oxidizing condition failed to preduce toxoid. No evidence that toxoid formation is due to the disappearance of free NH_2 groups has been obtained. Some possible mechanisms are discussed.
BENJAMIN HARROW

The mechanism of sugar excretion. I. Glucose. TSANG-G. NI AND POUL B. REHBERG. *Biochem. J.* **24**, 1039–46(1930).—According to the filtration-reabsorption theory, the mechanism of glucosuria must be the failure of the reabsorption to increase as fast as the filtration of sugar increases with rising blood sugar. The percentage of sugar in the reabsorbed fluid varies within wide limits.
BENJAMIN HARROW

Changes in the amount of blood chloride during asphyxiation. I. TAKESHI SASO. *J. Biochem.* (Japan) **12**, 161–85(1930).—During acute asphyxia the chlorides of the whole blood increase appreciably almost within the first min. and continue to do so until death. This is also the case in the plasma, the decrease in plasma chlorides so often observed in animals dying from asphyxia being a postmortem phenomenon. When the animal is asphyxiated slowly the Cl of the whole blood increases gradually, reaching a max. in 10–20 min., then remaining unchanged until death occurs. As the plasma Cl, however, becomes too low, the whole blood Cl also diminishes some-

what but still remains above the initial level to the very end. In prolonged asphyxia the plasma Cl increases during the first 10–20 min., then decreases gradually and just before death falls to a subnormal level. If, however, death results within 30 min. the Cl is affected exactly as was the case in acute asphyxia. In the early phase of prolonged asphyxia, especially that produced by pneumothorax, there is an initial drop in the Cl of blood and plasma. This is attributed to an hyperventilation alkalosis. In acute asphyxia the Cl increase in whole blood resulted from the increased Cl content of the red cells, and plasma and from the relative increase in the plasma vol. due to a reduction in the no. of red cells. In prolonged asphyxia the increased Cl content of the whole blood in the early stages is due to the rise in Cl of the red cells and of the plasma, but subsequently to the high Cl content of the cells alone. In acute asphyxia the no. of red cells is always diminished, while in prolonged asphyxia there is always an increase in the cells. In neither case is the hemoglobin content changed. S. M.

The citric acid content of urine in acidosis and alkalosis. Otto Österberg. *Biochem. Z.* **226**, 162–3(1930).—The normal citric acid output in the urine per day is 0.2 to 7.0 g. Abnormally low values for citric acid are found in cases of serious kidney insufficiency or in acidosis. In chronic uremia no citric acid can be found at all, and in diabetic coma only traces are found. On the contrary, the citric acid output is greater following the administration of $NaHCO_3$. S. Morgulis

Fagopyrism. A biochemical investigation and a critical study of its pathogenesis. H. E. W. Lutz and G. Schmid. *Biochem. Z.* **226**, 67–96(1930).—Fagopyrism or "buckwheat sickness" has been studied on carefully made exts. which have been tested on animals. The presence of a fagopyrum anthocyanin in the flower of the plant is very probable. The buckwheat chlorophyll which is present intact in the ether exts. is not the pathogenic factor of the photosensitivity resulting from the buckwheat. The plant after extn. with alc. is inactive photobiologically but it is also an insufficient food. The aq. portion of the alc. ext. of the flower causes severe intoxication in guinea pigs which is manifest as injury to the central nervous system. A study of the relation of the pathogenesis of fagopyrism to the source and intensity of the light as well as the duration of the illumination shows that this obeys the Bunsen-Roscoe law, and must therefore be a photochem. phenomenon. Feeding with whole buckwheat seeds does not lead to the appearance of beriberi symptoms either in pigeons or in guinea pigs. When the alc. ext. of fagopyrum flowers was dild. with isotonic NaCl to reduce the alc. content to 30% and injected subcutaneously into guinea pigs, these developed secretory conjunctivitis in the unpigmented but not in the pigmented eyelid because of the increased photosensitivity. S. Morgulis

The water-soluble phosphatides of bacteria. M. Eisler and Z. v. Gulaesy. *Zentr. Bakt. Parasitenk.*, 1 Abt., **117**, 500–5(1930).—Twenty-four hr. digestion of typhoid and mouse typhoid bacilli in distd. water at 20° gave a product, probably protein free, which was sol. in water and pptd. by alc. It contains choline and is analogous to the water-sol. phosphatides which have been extd. from plant cells. Intravenous injection of this substance from typhoid bacilli in rabbits produced a serum which gave strong complement binding and agglutination reactions with *B. typhosus* and weak ones with *B. typhi murium*. The substance from mouse typhoid also gave stronger reactions with the homologous organism. John T. Myers

Anaphylaxis against lipoids. M. N. Lebedeva and L. B. Levinson. *Zentr. Bakt. Parasitenk.*, 1 Abt., **117**, 519–35(1930).—Serum from guinea pigs sensitized to hog serum causes contraction of perfused intestine, while normal guinea pig serum does not. Lecithin increases the contraction with sensitized serum but has the same effect in the case of non-sensitized serum. There was no evidence of antigenic power on the part of lecithin. Serum plus lecithin has no more desensitizing action than serum alone. John T. Myers

The influence of lead on agglutinin and precipitin formation in animals already treated with lead. Friedrich-Wilhelm Bickert. *Zentr. Bakt. Parasitenk.*, 1 Abt., 118, 159–63(1930); cf. *C. A.* **24**, 656.—In animals previously immunized and treated with Pb by subcutaneous injection of a 5% soln. of $Pb(OAc)_2$ and the titer allowed to drop, the titer came back up more quickly than in control animals not treated with Pb. John T. Myers

The sugar utilization by trypanosomes (in vitro at 37°) and its meaning in the pathology of trypanosome infections. P. Regendanz. *Zentr. Bakt. Parasitenk.*, 1 Abt., 118, 175–86(1930).—Trypanosomes *in vitro* in blood-serum mixts. utilize sugar. There is little difference between pathogenic and non-pathogenic varieties. J. T. M.

The hemotoxin in Sarcosporidia. Shinichi Sato. *Zentr. Bakt. Parasitenk.*, 1 Abt., 118, 189–96(1930).—See *C. A.* **24**, 5858. John T. Myers

Blood normals for cattle; some pathological values. JOHN ALLARDYCE, R. H. FLEMING, F. L. FOWLER AND R. H. CLARK. *Can. J. Research* 3, 120–4(1930).—Samples of cattle blood were analyzed and the concns. of 10 constituents detd., *i. e.*, cholesterol, sugar, non-protein N, urea N, amino acid N, creatine, creatinine, Ca, inorg. P and chlorides. The normal range for these was found to be nearly the same as that in human blood. Changes in feed from corn to sunflower silage markedly influenced the cholesterol content. Blood samples of cattle suffering from red water, tuberculosis, abortion, blood poisoning, malignant growths and pyelonephritis were analyzed and the constituents were in general within the normal range. Tables accompany the paper. J. W. SHIPLEY

A few colloidal chemical characteristics of rabbit blood as effected by Bordet's bacillus. SETSUNOSUKE TAKAHASHI. *Sei-i-kwai Med. J.* 49, No. 1, 116–30 (German abstract 7–8)(1930).—When *B. pertussis* (I) is injected into the rabbit vein, the sedimentation velocity of the blood increases soon after the injection, and gradually decreases to the normal after 10 days. The colloidal instability of the serum also undergoes similar changes. These changes are greater and more persistent when greater amts. of I are used. There are also considerable changes in resistance against saline and saponin solns. S. TASHIRO

Accelerating action of the blood coagulation by eclampsia urine. KIKUZO SAKURAI. *Sei-i-kwai Med. J.* 49, No. 4, 27–37 (English abstract 6–7)(1930).—It was shown before (cf. *C. A.* 24, 5833) that an injection of the placental ext. into the blood of rabbits results in an appearance of the blood coagulant in the urine. S. examd. the urine of the normal and various pathol. cases for presence of the blood coagulant. The results show that in the first place, normal nitrogenous urinary constituents such as urea, uric acid, creatinine and hippuric acid do not accelerate blood coagulation. Neither normal nor nephritic urine that contains different amts. of albumin accelerates the blood clotting. The urine of eclampsia patients taken during or after the attack shortens the coagulation time of the blood 50–75%, while that of pregnant women excreting a large amt. of albumin does not contain any coagulant. Conclusion: During pregnancy the tissue fibrinogen of the placenta must go into the mother's blood; and if the amt. goes above a certain limit by some unknown metabolic disturbances, an eclamptic attack may occur, followed by an excretion of the tissue fibrinogen of the placenta by the kidney. S. T.

Relationship between diphtheria toxin and blood sugar. TAMOTSU USUI. *Sei i-kwai Med. J.* 49, No. 4, 38–50 (German abstract 7–8)(1930).—Relationship between diphtheria toxin on the blood sugar was investigated with clinical and exptl. materials, blood sugar being detd. by Bang's method. The value of the first detn. of each of 13 light cases (3–96 hrs. after the onset of the disease) lies between 0.0795 and 1.337%, slightly higher than that of the normal. The subsequent analysis of the blood of the same patients during the course of the disease shows practically no difference from that of the normal. The blood sugar of 5 more serious cases shows much greater amts. (0.1513–0.2258%); and of these, the more favorable ones were those whose blood sugar returned to the normal within a few days. The effects of the toxin on the exptl. animals (guinea pig and rabbit) are much more marked, but this hyperglucemia is found only when the toxin or the organisms are injected subcutaneously, the intravenous injection showing no effect at all. Whether or not this toxin has a specific action on the blood sugar is a question, but U. believes that the diphtheria antitoxin lowers this hyperglucemia to a certain degree. S. T.

Studies on the sedimentation velocity of the red blood corpuscles. I. KEIZO MIYOSHI. *Sei-i-kwai Med. J.* 49, No. 6, 1–12 (English abstract 1)(1930).—The factors influencing the sedimentation velocity (I) of the rabbit blood corpuscles are analyzed by using Westergren's method. The results show that the presence of hydrosols such as gelatin and agar agar in the blood plasma increase I, although gum arabic is strangely indifferent. This accelerating effect of the hydrosols occurs even without the plasma present. The plasma accelerates I more than the serum. Of the blood proteins isolated from the blood, the fibrinogen accelerates I most, next serum globulin and serum albumin least. Conclusion: The accelerating factor of I exists in both the plasma and corpuscles. II. *Ibid* 13–34 (English abstract 1–2).—The sedimentation velocity (V) of the red corpuscles is detd. to see if it has any relationship to the cholesterol content of the serum (C). V of the blood of 50 pulmonary tuberculosis patients is 3–11 times faster than that of the normal, while C is on the av. 118 mg. per 100 cc. serum, which is within the limit of the normal. In pregnant women, the increase of C does not occur till the 4th month, while V is markedly increased in the second month. In 50 cases of beriberi, where the av. C is below normal (88 mg.), the av. V is normal.

When the rabbits are fed with lanolin in such an amt. as to increase C 4–7.5 times, their V is the same as that before the feeding. *In vitro*, an addn. of cholesterol to the blood increases V, while that of lecithin retards it. With a ratio of these two in 10:1, V is still accelerated, while a 3:1 ratio retards it. The analysis of the blood of 50 patients, whose V varied considerably, showed no relationship between V and the ratio between C and lecithin. Conclusion: Neither the increase of the ratio as suggested by Kürten and Linzenmeier nor the abs. value of C as suggested by Grossmann and Adberhalden can be responsible for V. S. TASHIRO

Experimental fibrous osteodystrophy (ostitis fibrosa) in hyperparathyroid dogs. HENRY L. JAFFE AND AARON BODANSKY. *J. Exptl. Med.* 52, 669–94(1930).—Parathyroid ext. (parathormone Collip) can be injected into puppies in increasing amts. for long periods without fatal results. Thus time is allowed for bone changes to develop. Long-continued injection leads to progressive decalcification and resorption of the existing bone, to fibrous replacement of the marrow and to the production of the other features characteristic of ostitis fibrosa. Deformities eventually appear. It is safe to assume that the bone changes produced by hyperparathyroidization have the same pathogenesis as those observed in clinical cases believed to be instances of hyperparathyroidism—that is, cases with a neg. mineral balance and decalcification of the skeleton. C. J. WEST

Comparison of the chemical alterations in the blood of rats infected with pathogenic and non-pathogenic trypanosomes. RICHARD W. LINTON. *J. Exptl. Med.* 52, 695–700(1930).—Blood samples from rats infected with *Trypanosoma lewisi* give normal values for lipoid P, lecithin, CO_2-combining capacity and liver glycogen. When these results are compared with the results of similar expts. with *T. equiperdum* infections, on the basis of the concn. of trypanosomes in the blood, it is found that the pathogenicity of the latter organism does not depend upon its nos. as affecting the blood but that it must be in some other way injurious to the host. Whether the injury is due to a true toxin, an endotoxin or mech. interference, is not yet known. C. J. WEST

Serology of syphilis. I. Mechanism of the flocculation reactions. HARRY EAGLE. *J. Exptl. Med.* 52, 717–38(1930).—The lipoid antigen used in the serum diagnosis of syphillis, when colloidally dispersed in water, forms a relatively stable amphoteric suspension with predominantly hydrophilic properties. Although the colloidal particles flocculate at their isoelec. pt. (p_H 1.9), in more alk. reaction the neg. surface potential prevents their cohesion and must be depressed to 1–5 mv. before visible flocculation is obtained. The amt. of electrolyte necessary to depress this surface charge below its crit. value decreases somewhat with increasing concn. of the sol, but is uniformly large. In normal serum hydrophilic protein is adsorbed, forming a protective film around the individual lipoid particles, with a corresponding change in the cataphoretic potential and the isoelec. point toward those of serum protein; the crit potential is not affected and the lipoid remains as stable away from its isoelec. point as in the absence of serum. When the lipoid antigen is added to syphilitic serum, in addn. to this loose absorption of normal protein it combines more or less irreversibly with a specifically altered fraction of the serum globulin (reagin), demonstrable in the washed ppt. both chemically and by sensitization expts. Like adsorbed normal serum, it depresses the surface potential and causes a shift in the isoelec point, but there the similarity ends. The reagin-globulin is rendered water-insol. by its firm combination with the lipoid. The hydrophobic films of reagin have 5 times as great an affinity for each other as the original lipoid surfaces. The reagin-globulin on the lipoid particle can adsorb ("fix") complement; when this protein film is destroyed by heat coagulation the complement-fixing property is lost. The complete analogy between the flocculation reactions for syphilis and the so-called sp. reactions suggests that like agglutinins, precipitins, etc., reagin-globulin represents an antibody response to products of infection. **II. Physical basis of the Wassermann reaction.** *Ibid* 739–46.—The substance in syphilitic serum which is responsible for the Wassermann reaction is assocd. with the globulin fraction of serum. Every pos. Wassermann is accompanied by microscopic or submicroscopic aggregation, which is not an essential feature of the reaction; conversely, after every pos. flocculation test, the washed ppt. will fix complement. An excess of antigen removes both flocculating and complement-fixing substances completely. Heating the lipoid-reagin ppt. to 100° for 1 min. destroys the sensitizing film of reagin-globulin; the avidity for complement disappears simultaneously. Both the flocculating and complement-fixing properties of syphilitic serum are therefore detd. by the same substance, a sp. altered fraction of the serum globulin, reagin. The Wassermann reaction is thus entirely analogous to complement fixation by any antigen-antibody complex. **III. Explanation of the fortifying effect of cholesterol upon the anti-**

gen as used in the Wassermann and flocculation tests. *Ibid* 747–68.—When cholesterolized antigen is dropped into an excess of H_2O, the rapid flocculation of cholesterol (I) crystals is prevented by the fact that, as tiny aggregates form, they adsorb a protective surface of hydrophilic lecithin (*i. e.*, antigen) which endows the particles with its own stable surface properties and thus prevents further aggregation. The colloidally dispersed antigen-I particles have approx. the same isoelec. point, crit. potential and coagulation value as pure antigen particles of the same concn. This adsorption of antigen by the I nucleus is probably detd. by the fact that the former has a lower surface tension against H_2O; at any rate, many surface-active substances cause a similar stable dispersion of I. The colloidal suspension formed by antigen alone is very finely dispersed. I causes a marked increase in the no. of the particles which exceed the limits of dark field visibility, out of all proportion to its mass. The particles remain discrete until the I:antigen ratio exceeds 1:1, when slight microscopic aggregation is observed; microscopic flocculation is seen only when this ratio exceeds 5:1, when there is not sufficient antigen to act as an efficient protective colloid. I therefore causes a coarsened dispersion of antigen by forming a relatively large nucleus upon which antigen is adsorbed. The larger the antigen particle the greater is its avidity for regain per unit surface or mass. The coarsened dispersion caused by I completely explains the greater sensitivity of the cholesterolized antigen in complement fixation. From the consideration of the unsatisfactory nature of I as a sensitizer for antigen, among which is its slight soly. in EtOH, a group of substances have been developed, to be reported later, which make possible an antigen which is 2–10 times as efficient in the Wassermann test as any now available. C. J. WEST

H—PHARMACOLOGY

A. N. RICHARDS

Effect of thyroxine upon normal, hypophysectomized and thyroidectomized tadpoles. BENNET M. ALLEN. *Proc. Soc. Exptl. Biol. Med.* **27**, 35–7(1929).—*Rana aurora* tadpoles, kept for 4 months after the removal of the thyroid gland anlage or the buccal anlage of the hypophysis, metamorphosed rapidly and to an equal degree with controls when placed in thyroxine solns. of 1–500,000, 1–1,000,000 and 1–2,000,000 concns. for periods of 11 to 15 days. C. V. B.

Effect of morphine sulfate by mouth on oxygen consumption in normal humans. H. H. ANDERSON. *Proc. Soc. Exptl. Biol. Med.* **27**, 102–3(1929).—The oral administration of morphine sulfate in doses of 0.1 mg. to 0.5 mg. per kg. body weight was followed within 1 hr. by a slight decrease in O_2 consumption. C. V. BAILEY

Effect of amytal anesthesia on glucose tolerance. J. M. D. OLMSTED AND GEORGE GIRAGOSSINTZ. *Proc. Soc. Exptl. Biol. Med.* **27**, 103–6(1929).—In the dog under amytal anesthesia the pyloric sphincter is kept so tightly closed that sugar introduced into the stomach cannot pass into the duodenum and so be absorbed; absorption from the duodenum itself is greatly diminished. These findings indicate paralysis of the parasympathetic autonomic nervous system. C. V. BAILEY

Exogenous arginine as the precursor of creatine in the dog. R. LORIMER GRANT, ADAM A. CHRISTMAN AND HOWARD B. LEWIS. *Proc. Soc. Exptl. Biol. Med.* **27**, 231–3 (1929).—In the dog, arginine by mouth for 35 days had no effect on the excretion of urinary creatine or creatinine; small doses of creatine by mouth caused a prompt increase in the output of both of these catabolites. C. V. BAILEY

Effect of sodium amytal on the hyperglucemia due to morphine. SELLING BRILL. *Proc. Soc. Exptl. Biol. Med.* **27**, 265–7(1930).—In the dog, Na amytal given intraperitoneally in a dose of 50 mg. per kg. of body wt. greatly inhibited the hyperglucemia induced by the subcutaneous injection of morphine sulfate, 10 mg. per kg. of body wt., given 20 min. later. C. V. BAILEY

Toxicity of acetarsone (stovarsol) and its calcium and sodium salts on oral administration to rabbits and cats. HAMILTON H. ANDERSON AND CHAUNCEY D. LEAKE. *Proc. Soc. Exptl. Biol. Med.* **27**, 267–70(1930).—The min. lethal dose of com. acetarsone given orally to the cat and to the rabbit is between 125 and 175 mg. per kg. of body wt. This is about 4 times the recognized toxicity and indicates the necessity of a revision of the recommended therapeutic dose. The Ca and Na salts of acetarsone seem to be equally toxic. C. V. BAILEY

Observations on the formation of wheals. III. The participation of an unidentified tissue substance. H. L. ALEXANDER, W. K. WEAVER AND F. S. MCCONNELL. *Proc. Soc. Exptl. Biol. Med.* **27**, 486–7(1930).—In the dog, wheals following the intradermal injection of histamine plus skin ext. were larger than those made by histamine alone. C. V. BAILEY

Fractionation of Australian snake venoms. I. Venom of death adder (Acanthophis antarcticus). C. H. KELLAWAY, M. FREEMAN AND F. E. WILLIAMS. *Australian J. Exptl. Biol. and Med. Sci.* **6**, 245–60(1929).—Heating the proteose fraction of the venom caused a diminution of activity. Quant. fractionation of the venom by extn. with 45% EtOH is unattended by any loss of total activity of the venom. When injected subcutaneously in mice or guinea pigs the insol. fraction has but little of the toxicity of the whole venom whereas it possesses all the coagulant activity. The sol. fraction contains the "neuro-toxic" principle, which has a curare-like action. The hemolytic activity is evenly distributed in both fractions, whereas more of the substance which stimulates plain muscle is present in the sol. fraction. Both fractions are equally toxic by intravenous injection in mice and guinea pigs. B. C. A.

A bactericidal study of the value of mercurochrome as a vaginal antiseptic with particular reference to its use in obstetrical cases. H. W. MAYES AND SILKA ULLIAN. *Surgery, Gynecol. Obstet.* **51**, 345–52(1930).—The use of mercurochrome as a vaginal antiseptic during labor reduces the bacterial count of the birth canal. J. B. B.

Sodium amytal-nitrous oxide anesthesia for thyroidectomy. FRANK B. RAMSEY AND WENDELL D. LITTLE. *Surgery, Gynecol. Obstet.* **51**, 352–5(1930).—Na amytal is useful in the preoperative prepns. of patients in thyroid cases to render them free from apprehension. Adequate anesthesis may then be obtained by the use of N_2O with sufficient O to prevent cyanosis. J. B. BROWN

Tribromethyl alcohol (avertin) anesthesia. CHARLES S. WHITE AND JOSEPH KREISELMAN. *Surgery, Gynecol. Obstet.* **51**, 361–4(1930).—The use of tribromethyl alc. with gas or novocaine combines in the highest degree excellence and safety in anesthesia. J. B. BROWN

Aqueous diuresis. L. AMBARD AND F. SCHMID. *Compt. rend. soc. biol.* **101**, 180–2 (1929).—An intestinal diuretic homone was prepd. as follows: 1 kg. of mucosa from beef small intestine was acidified with 40 cc. of 10 *N* H_2SO_4, treated with 1 vol. of acetone and heated to 70° for 2 hrs. Five vols. of acetone were added to the filtrate; the ppt. was taken up in 50 cc. H_2O and neutralized; 3 vols. of acetone were added. The resulting ppt. was rejected; the ppt. obtained by adding 4 vols. of acetone to the filtrate was retained. The min. effective dose, given to anaesthetized rabbits, was 0.2 mg. per kg.; the vol. of urine was doubled. The effect of small doses is very rapid. Beside the diuretic action, a lowering of the blood pressure (3–4 cm. Hg) was observed; the polyuria, however, is not related to the shock. The ext. had no effect on human subjects. Exts. of kidney and spleen were inactive. B. C. BRUNSTETTER

The venoms of Oxyuranus maclennani and of Pseudechis scutellatus. C. H. KELLAWAY AND F. ELEANOR WILLIAMS. *Australian J. Exptl. Biol. and Med. Sci.* **6**, 155–74(1929).—The lethal subcutaneous dose of *Oxyuranus* venom ranged from about 1 to 0.1 mg. per kg. from monkeys, rabbits, guinea pigs, to rats. The lethal intravenous dose was much smaller. The venom causes intravascular clotting, is only feebly hemolytic, but powerfully neurotoxic. The venom of *Pseudechis* has only $^1/_{10}$ to $^1/_5$ of the toxicity of the former. It is powerfully anticoagulant and hemolytic but only feebly neurotoxic. H. L. D.

Experimental studies on the water economy of the skin by means of the wheal test. II. Effect of substances applied locally onto the skin or acting from the blood, upon the resorption of the intracutaneous saline wheal. D. ADLERSBERG AND A. PERUTZ. *Arch. exptl. Path. Pharmakol.* **151**, 129–45(1930); cf. *C. A.* **24**, 4814.—Xylene hastens and EtCl delays resorption when applied locally to the skin. Amyl nitrite, theophylline and pituitrin given systemically all accelerate resorption. The effect of the first 2 substances is probably due to vasodilatation; that of the pituitrin, as well as the protracted effect of theophylline, must be due to some obscure tissue factor. Pituitrin, given simultaneously with either of the other two, causes a mutual cancellation with no observable effect, a paradox which is unexplained; possibly there is a central effect. **III. The effect of centrally acting drugs (hypnotics) on the resorption of the intracutaneous saline wheal.** *Ibid* 257–66.—Narcotics affecting either the cerebral cortex (methane, paraldehyde) or brain stem (chloretone) do not affect velocity of resorption. The former do not affect the accelerating action of theophylline or pituitrin. Chloretone, however, accentuates the action of theophylline, presumably by preventing the central vasoconstrictor effect of the drug, allowing the peripheral vasodilatation by the xanthine ring. Chloretone inhibits the accelerating action of pituitrin, indicating that the latter acts upon the central nervous system. **IV. Clinical contributions.** *Klin. Wochschr.* **9**, 1165–8(1930); cf. *C. A.* **24**, 4814.—The velocity of absorption was detd. in a no. of pathol. conditions. A case of diabetus insipidus, in a condition of great thirst, showed an enormously accelerated resorption time (3 min.) lengthened

to 35 min. after a few days on an unlimited water supply. In fever, diabetes and Basedow's disease, there is increased resorption. Pituitrin, despite the vasodilation it causes, brings about increased resorption, possibly because of a direct extravasal action upon the tissues. Amyl nitrate increases the velocity of resorption only in the upper half of the body, corresponding to the areas where it causes vasodilatation. Pain accelerates resorption, possibly because of the effect on the vegetative nervous system. H. E.

Further studies on permeability and narcosis. K. J. ANSELMINO AND E. HOENIG. *Arch. ges. Physiol. (Pflüger's)* **225**, 56–68(1930).—A study was made of the effect of alc. and urethan anesthetics on the permeability of the red corpuscle towards glycerol, erythritol, arabinose, xylose, glucose and mannose. The results are explicable on the assumption that the narcotics are adsorbed on the cell membrane so as to alter the effective pore diams. ARTHUR GROLLMAN

Relations between pituitary and pancreas. B. A. HOUSSAY. *Endokrinologie* **5**, 103–16(1929); *Physiol. Abstracts* **14**, 582–3.—The relations are treated under the following groups: (1) antagonistic action between pituitary ext. and insulin; (2) action of pituitary ext. on the secretion of insulin; (3) action of insulin on the structure and the secretion of the pituitary; (4) increase of the sensitiveness of pituitariless animals to the action of insulin; (5) changes in the pancreas in animals deprived of their pituitary; (6) pancreas-diabetes and extirpation of the pituitary. Numbers (1) and (4) are considered to be the most certain and the most significant of these relations. E. C. K.

The influence of urea upon blood clotting. I. Thrombin clotting. J. H. FOULGER AND C. A. MILLS. *Am. J. Physiol.* **94**, 51–9(1930).—Urea, added to blood, produces at least 3 effects: (1) In low concns. it accelerates clotting by the liberation of reserve supplies of thrombin precursors (cephalin and prothrombin). (2) In higher concns. (5 g. per 100 cc.) it retards clotting by delaying the union of thrombin with fibrinogen. (3) In still higher concns. (8 g. per 100 cc.) it delays or inhibits clotting by peptizing the fibrin and so preventing its orientation into the solid structure of clot. J. F. L.

The effect of intravenous injection of calcium lactate upon gastric secretion. G. R. COWGILL AND T. L. RAKIETEN. *Am. J. Physiol.* **94**, 165–9(1930).—Variations in blood Ca, produced by intravenous injection of Ca lactate, did not affect the rate of gastric secretion in gastric pouch dogs. J. F. LYMAN

The physiological action of the venom of the honey bee (Apis mellifera). H. E. ESSEX, J. MARKOWITZ AND F. C. MANN. *Am. J. Physiol.* **94**, 209–14(1930).—The physiol. reactions to the bee venom closely approximate those of rattlesnake venom. It produces fall in blood pressure, contraction of virgin guinea pig uterus, occlusive bronchospasm, intradermal reactions similar to that of histamine, hemolysis and inhibition of the isolated perfused rabbit heart. J. F. LYMAN

Hemolysis of the erythrocytes of amphibia. H. A. CHARIPPER. *Am. J. Physiol.* **94**, 278–84(1930).—The hemolytic action of saponin, Na taurocholate and Na oleate on amphibian erythrocytes was studied. Time-diln. curves, resistance values and the microscopic appearance of the cells in the presence of the lysin are reported. J. F. L.

The effect of liver on the blood-sugar level and on the sugar excretion of depancreatized dogs. M. T. DE PENCIER, S. SOSKIN AND C. H. BEST. *Am. J. Physiol.* **94**, 548–52(1930).—The feeding of raw liver to depancreatized (diabetic) dogs did not cause a decrease in blood sugar or a decrease in sugar excretion through the kidneys. J. F. LYMAN

The mechanism of adrenaline action. VII. Changes in the glycogen, lactic acid and phosphate content of muscle. GERTY T. CORI. *Am. J. Physiol.* **94**, 557–63 (1930); cf. *C. A.* **24**, 4835.—After the administration of adrenaline to rats there was: (1) a decrease in muscle glycogen; (2) no change in phosphocreatine of the muscle; (3) a slight decrease in inorg. phosphates; and (4) a marked rise in the lactic acid content of the blood and muscle. J. F. LYMAN

Determination of circulation time. T. KOPPANYI AND A. LIEBERSON. *Am. J. Physiol.* **94**, 564–7(1930).—The injection of 0.25 mg. of adrenaline-HCl (1:1000) into the left common carotid artery of the cat was followed usually within 1 sec. by max. dilatation of the left pupil, and from 6 to 9 secs. later by dilatation of the right pupil. The time between the pupillary responses in the eyes is thought to represent total circulation time. J. F. LYMAN

The effect of adrenaline on muscle glycogen in the absence of the liver, and a modification of the operation for liver removal. W. M. FIROR AND G. S. EADIE. *Am. J. Physiol.* **94**, 615–8(1930).—The administration of adrenaline to cats after the removal of the liver had no apparent effect on the rate of glycogen disappearance from the muscle nor on the rate of decrease in blood sugar. Conclusion: Adrenaline has no

peripheral action on muscle glycogen or on the rate at which glucose leaves the blood. J. F. LYMAN

The revival of comatose adrenalectomized cats with an extract of the suprarenal cortex. W. W. SWINGLE AND J. J. PFIFFNER. *Science* 72, 75–76(1930).—An ext. which is low in adrenaline and solids has been prepd. from the suprarenal cortex of beef. This is capable of keeping adrenalectomized cats alive for a hundred days (an arbitrarily selected period after which the treatment is discontinued). This ext. will also revive cats in a comatose condition after the removal of the adrenals and bring them into a normal condition in about 70 hrs. C. M. M.

Plasma calcium and inorganic phosphorus following intravenous injection of parathyroid extract: A study on the source of mobilized calcium. CHIAO TSAI AND FONG-YEN HSU. *Chinese J. Physiol.* 4, 265–72(1930).—The intravenous injection of Collip's parathyroid ext. results in a rise in the plasma Ca and inorg. P in dogs. The rise of Ca occurs immediately but the rise of P begins 2 hrs. after the injection. The recovery of P is slower than that of Ca. The ratio of the abs. value of increase of these 2 constituents is approx. 2:1, supporting the hypothesis that the mobilized Ca and P are derived from $Ca_3(PO_4)_2$ of bone. L. A. MAYNARD

The effect of intravenous injection of sodium oxalate and citrate on the concentration of plasma calcium and inorganic phosphorus. CHIAO TSAI AND FONG-YEN HSU. *Chinese J. Physiol.* 4, 273–87(1930).—The intravenous injection of either Na oxalate or Na citrate into normal dogs causes an immediate drop in plasma Ca. The oxalate causes the larger drop. With both salts a rapid recovery occurs. Administration of these salts to thyroparathyroidectomized dogs, prevented from tetany attack by Ca lactate and milk powder or Ringer-lactate injection, causes a further drop of plasma Ca. The recovery is extremely slow. The injection of the Na citrate to both normal and thyroparathyroidectomized dogs is followed by a brief period of convulsions. This does not occur with Na oxalate. Parallel to the drop in Ca following citrate and oxalate injection there is a slight depression of plasma inorg. P. During the recovery of Ca the P level is much elevated, the elevation being greater in the normal animals. L. A. MAYNARD

Resistance of omnivorous and vegetarian rats against certain poisons. TUNG-TOU CHEN AND C. PAK. *Chinese J. Physiol.* 4, 289–94(1930).—Omnivorous and vegetarian rats are equally resistant to strophanthin and strychnine sulfate subcutaneously injected. Vegetarian rats are twice as resistant to ephedrine-HCl and slightly more resistant to morphine-HCl, NaCN and CH_3CN. L. A. MAYNARD

Studies on the mode of fixation of cocaine hydrochloride on the nerve fibers. JEAN REGNIER AND GUILLAUME VALETTE. *Compt. rend.* 190, 1453–4(1930); cf. *C. A.* 23, 3979, 4743.—It has been shown that the lowering of chronaxie of nerve fibers by cocaine is not proportional to concn. of poison. By plotting the concn. of soln. against fall of chronaxie a parabolic curve is obtained. It is thought that the cocaine is fixed upon nerve fiber by a process of adsorption. To test this hypothesis, it is first shown that fixation of cocaine-HCl on animal charcoal follows the adsorption equation of Freundlich. Then the fixation of cocaine-HCl on nerve fibers is tested. When the values for mol. concn. of cocaine are plotted against the no. of mols. of cocaine fixed per g. of nerve fiber, a parabolic curve is obtained. The curve which expresses the relation between the logs. of the preceding values is rectilinear. By using the mean value of the angles formed by this latter curve with the abscissa as axis, the tangent is equal to 0.52. Thus this tangent corresponds to $1/n$ of the logarithmic expression for the adsorption curve: $\log x/m = K + 1/n \log C$. The rapidity of fixation, the form of the curve, and the value of $1/n$ indicate that cocaine is fixed upon nerve fiber by a process of adsorption. N. M. NAYLOR

Chemical burns. RENÉ CHESNEAU. *Bull. soc. ind. Rouen* 58, 254–7(1930).—An outline is given of the chem. and physiol. action on skin-burns of various chemicals, with methods of treatment and the principles applying in each case. For burns due to acids and alkalies, washing with large amts. of H_2O is recommended: for phenol burns, EtOH or a soln. of Na_2SO_4; for cyanides, $KMnO_4$ or NH_4 polysylfide; for Na, removal of the Na followed by washing with H_2O and tannic acid; for P, a soln. of $CuSO_4$ followed by H_2O with a little $Mg(OH)_2$; for metallic salts, $NaHCO_3$ followed by tannic acid; for chromic acid, Na polysulfide followed by tannic acid. Several agents for treating ordinary burns are mentioned, including tannic acid, which acts as a destroyer of alkalies, an antiseptic and a coagulant. The treatment of eye-burns is also described. I. H. ODELL

Charcoal treated with atropine in digestive therapeutics. LEFÈVRE. *Semana méd.* (Buenos Aires) 1930, II, 133–5.—Atropine, absorbed on charcoal, is recommended

for the treatment of spasms of the intestine. Its action is local only and general poisoning is impossible. A. E. MEYER

The pharmacology of Xysmalobinum. J. M. WATT. *J. Pharmacol.* **38**, 261–70 (1930).—M. l. d. and clinical symptoms of poisoning in the frog, cat, rabbit and dog are described. The glucoside causes slowing of the heart, constriction of blood vessels, rise in blood pressure. It causes strong constriction of the isolated intestine and uterus of rabbit, guinea pig and cat, and of the bladder of the cat and guinea pig. Contraction of the bronchi in the intact animals causes severe respiratory embarrassment. The glucoside produces diuresis in the rabbit and cat and increased salivation in the dog. C. RIEGEL

Investigation of insulin-like properties of uvursin, oxycatalyst and Solanum sanitwongsei berries. M. LOUISA LONG AND FRITZ BISCHOFF. *J. Pharmacol.* **38**, 313–25(1930).—None of the prepns. had hypoglucemic properties in rabbits. Oxycatalyst caused kidney and liver damage as shown by the blood chemistry (urea N, amino acid N), and histological study. C. RIEGEL

Magnesium oxide as an aid to the antipyretic action of phenacetin in dogs. J. E. WINTER, C. H. RICHEY AND H. G. BARBOUR. *J. Pharmacol.* **38**, 343–7(1930).—Phenacetin and MgO by stomach tube had an antipyretic effect on rabbits receiving hay infusion. The results suggest a synergic effect. C. RIEGEL

Further studies on the effect of morphine sulfate, atropine sulfate, and hyoscine hydrobromide upon the intact intestine in unanesthetized dogs. C. M. GRUBER, W. W. GREENE, C. S. DRAYER AND W. M. CRAWFORD. *J. Pharmacol.* **38**, 389–400 (1930).—In dogs with Thiry-Vella fistulas, morphine abolishes the decreased tonus produced by atropine. Atropine abolishes the increased tonus produced by morphine. Hyoscine has the same effect as atropine. C. RIEGEL

Further observations on the effect of pituitary extract and morphine sulfate upon excised dog's intestine. CHARLES M. GRUBER AND GARRETT PIPKIN. *J. Pharmacol.* **38**, 401–10(1930).—Small doses of pituitary ext. caused increased tonus, while large doses caused a decrease in tonus. Morphine increased tonus and occasionally the height of contraction. C. RIEGEL

The immediate anti-diuretic action of pituitary extract. JAMES B. ROSS AND R. L. STEHLE. *J. Pharmacol.* **38**, 451–60(1930).—In dogs with permanent bladder fistulas, and with a catheter in one ureter to the renal pelvis, administration of pituitary ext. caused immediate cessation of urine flow on both sides, and flow was resumed later at approx. the same time on both sides. The same diminution of secretion occurred even if no fall in blood pressure took place. Conclusion: Ureteral spasm is not the chief factor in causing the anti-diuretic effect. C. RIEGEL

The action of pituitary extract upon blood pressure. B. B. RAGINSKY, JAMES B. ROSS AND R. L. STEHLE. *J. Pharmacol.* **38**, 473–80(1930).—The results of Gruber on the effect of pituitary ext. on blood pressure in unanesthetized animals are confirmed. In dogs under chloretone anesthesia pituitary causes a rise in blood pressure, unaffected by vagotomy. With very large doses cardiac failure causes a fall in pressure following an initial rise. In dogs under ether there is a mixed effect detd. by the depressant cardiac action and vasoconstrictor action. With Na luminal the cardiac action usually predominates. C. RIEGEL

Studies on the colloid chemistry of antisepsis and chemotherapy. I. The mode of combination of antiseptic dyes with proteins. ARTHUR D. HIRSCHFELDER AND HAROLD N. WRIGHT. *J. Pharmacol.* **38**, 411–31(1930).—A viscose sac contg. distd. water was placed in a soln. contg. egg albumin and a dye (crystal violet, malachite green or brilliant green), and the amt. of dye diffusing into the sac during 7–8 days estd. colorimetrically. The difference between the amt. of dye diffused and the total amt. equals the amt. held back by protein. The results followed the Freundlich adsorption isotherm equation, and the conclusion was that the dye is adsorbed on the protein rather than chemically bound by it. **II. Does the fraction of an antiseptic which has been adsorbed on protein still exert an antiseptic action?** HAROLD N. WRIGHT AND ARTHUR D. HIRSCHFELDER. *Ibid* 433–49.—The reduction of antiseptic efficiency (as measured by ability to inhibit gas production in a yeast-sugar mixt.) of crystal violet, malachite green or brilliant green in the presence of egg albumin is not parallel to the amt. of dye adsorbed on the protein, *i. e.*, the fraction of dye adsorbed exerts some antiseptic action. The concn. of dye and CO_2 production by yeast in a given time are related by the expression $1/M_2 - M_1 \log C_1M_1/C_2M_2 = K$, where M_1 and M_2 are the amts. of gas produced at concns. C_1 and C_2. C. RIEGEL

Hibernation of the thirteen-lined ground squirrel, Citellus tridecemlineatus (Mitchill). IV. Influence of thyroxine, pituitrin and desiccated thymus and thyroid on

hibernation. GEORGE E. JOHNSON AND VIRGINIA B. HANAWALT. *Am. Naturalist* **64**, 272–84(1930).—"The feeding of desiccated thymus and thyroid in large doses to 27 and 23 animals, resp., resulted in no definite increase or decrease in the tendency of ground squirrels to hibernate when subjected to cold temps. The injection of thyroxine and pituitrin in doses which were, resp., 225 and 450 times the human dose on the basis of relative wts., produced no change in tendency to hibernate in 66 and 116 animals, resp., in comparison with the same no. of controls. The animals were subjected to cold temps. after the injections. The expts. indicate that the secretions of the thymus, thyroid and posterior pituitary are not important agents in the production or prevention of hibernation." G. SCHWOCH

The pharmacological activity of pyrrole and of the pyrryl alkyl ketones. General action in the frog. ANGELO RABBENO. *Arch. intern. pharmacodynamie* **35**, 377–421; *Chem. Zentr.* **1929**, II, 1318; cf. *C. A.* **23**, 3978, 4743.—In expts. with frogs R. compares the pharmacol. action of pyrrole with that of α-acetyl-, α-propionyl-, α-butyryl- and α-benzoylpyrrole. These ketones act qualitatively like the mother substance. The stage of excitability of the motor reflexes is soon followed by a slowly descending central paralysis. Death occurs because of the arrest of cardiac activity. In pyrrole both effects are of the same order of magnitude, while in the ketones the narcotic effect prevails. The toxic and the min. narcotic effects increase with increasing mol. wt. in the sense of an exponential function, but in a different manner. The pharmacol. activity is directly proportional to the b. p. of the substances examd.; it is inversely proportional to the m. p. and to the solubilities in water. With the ketones the toxic effect increases in the ratio $1:2:2^2$, while the narcotic effect increases in the ratio 1:5:10. Thus the mixed pyrrole ketones and aromatic ketones have the narcotic action in common, but they differ quantitatively because in the series of the mixed aromatic ketones the activity decreases with increasing mol. wt., while it increases with the pyrrole ketones. G. SCHWOCH

The influence of spleen, thyroid and insulin on the carbon dioxide content and on the hydrogen-ion concentration of the blood. II. The influence of insulin and the mutual relation between insulin and spleen. K. ICHIKAWA. *Folia endocrinol. Japon.* **5**, 1–2; *Chem. Zentr.* **1930**, I, 246.—After injection of 0.33 units of insulin per kg. rabbit the CO_2 content and the p_H of the blood decrease first and then increase to values beyond the normal level. When 0.33 units of insulin and glucose (1.5 g. per unit of insulin) are injected the CO_2 content rises immediately to beyond the normal level in the majority of the cases. The p_H changes in the same manner as after insulin alone. The extirpation of the spleen has an inhibiting action on the decrease or increase of blood CO_2 and p_H produced by insulin or insulin-glucose. G. SCHWOCH

The influence of the various endocrine organs on the hyperglucemia and lactic acid of the blood in chronic cyanide poisoning. I. Y. ODA. *Folia endocrinol. Japon.* **5**, 11–2; *Chem. Zentr.* **1929**, II, 1560–1.—Repeated subcutaneous injection of 1% KCN soln. (daily 2–6 mg. KCN per kg.) always causes an increase of sugar and lactic acid in the blood of rabbits. Simultaneous injection of insulin inhibits the increase. The blood of normal rabbits contains 10–15 mg. % lactic acid. **II.** *Ibid* 12–3; *Chem. Zentr.* **1929**, II, 1561.—Adrenaline and adrenal cortex ext. (Interrenin) inhibit or nullify the increase in blood sugar and lactic acid after chronic administration of KCN. The sensitivity of the rabbits against KCN is greatly increased by choline. G. S.

The relation between internal secretion and urea formation in the liver. I. The action of insulin. K. MORI. *Folia endocrinol. Japon.* **5**, 13; *Chem. Zentr.* **1929**, II, 1172.—The amt. of urea in the liver is augmented after peroral administration of NH_4HCO_3; under these conditions insulin injections augment the urea formation. At body temp. *in vitro* the aq. ext. of pulped liver is able to form urea from NH_4HCO_3. The urea-forming ability of pulped liver is intensified by addn. of insulin. **II. The action of various endocrine products.** *Ibid* 14; *Chem. Zentr.* **1929**, II, 1172–3.—The formation of urea from NH_4HCO_3 by pulped liver is inhibited by adrenaline; it is suppressed by thyroid ext., and it is augmented by testis, ovarian and corpus luteum exts. G. SCHWOCH

The effect of repeated glucose injections on the sugar tolerance of rabbits and on the blood sugar of rabbits treated with adrenaline or insulin. Y. ODA. *Folia endocrinol. Japon.* **5**, 16–7; *Chem. Zentr.* **1929**, II, 1173.—The behavior of the blood sugar of rabbits toward injection of $^1/_{10}$ to $^1/_7$ units of insulin or $^1/_2$ mg. of adrenaline per kg. was detd. before, during and after an injection series, in which 7 to 40% glucose solns. were injected for 6 to 40 days. The glucose administration intensified the insulin hypoglucemia and inhibited the adrenaline hyperglucemia. This effect lasted for a long time after the last glucose injection. G. SCHWOCH

The relation between thyroid and quinine with respect to the oxidase reactions of the organs. K. Mori. *Folia endocrinol. Japon.* 5, 21–2; *Chem. Zentr.* 1930, I, 244.—Feeding rabbits for several days with 0.2 g. quinine-HCl per day inhibits the oxidase reaction in the organs examd. (heart, kidney and liver). The diminution of the oxidase reaction does not occur in the thyroid-fed animal with simultaneous administration of quinine. Therefore quinine is believed to have an antagonistic action to the thyroid with respect to the oxidase reaction. G. Schwoch

The inhibiting influence of quinine on certain actions of the thyroid. Experimental studies on tissue respiration, metamorphosis and metabolism. T. Kambi. *Folia endocrinol. Japon.* 5, 22–3; *Chem. Zentr.* 1930, I, 244.—Thyroid ext. increases the respiration of liver and kidney sections of mice, while quinine inhibits it; under proper conditions the effects of both substances nullify each other completely. The acceleration of the metamorphosis of larvae of *Rana japonica* is inhibited by quinine. Quinine administered once or over a long period lowers the gaseous metabolism in larvae of *Bufo* fed with thyroxine. The tissue respiration and the anaerobic glucolysis of the intestinal loops of *Bufo* larvae fed with thyroxine increase considerably in the early stage. Quinine inhibits both reactions. G. Schwoch

The effect of choline on the nitrogen metabolism and on the salt elimination in the urine. K. Aoki. *Folia endocrinol. Japon.* 4, 24–5; *Chem. Zentr.* 1929, II, 1176; cf. *C. A.* 23, 2214.—Choline-HCl in doses of 10–20 mg. was injected for 4 to 5 days into dogs in the state of N equil. Total N, NH_3 and creatine were excreted in increased amts.; also the elimination of Me_2CO and $AcCH_2CO_2H$ was generally augmented. The salt excretion increases in the same proportion as the total N; thus the ratio Na-Cl:N remains unaltered. G. Schwoch

Pharmacological investigations on the local anesthetic S. F. 147 (Sandoz). Otto Gessner. *Narkose und Anästhesie* 2, 129–47; *Chem. Zentr.* 1929, II, 1319.—S. F. 147 is *N*-diethylleucinol *p*-aminobenzoate linked to methanesulfonic acid. The soln. is distinctly acid (p_H 5.107 in 0.1% soln.); it cannot be neutralized by $NaHCO_3$ without the formation of a ppt. Compared systematically with novocaine the toxicity of S. F. 147 was 4.5 times higher. It has a strongly hemolytic effect and is toxic to the heart in a pronounced degree. On account of these disadvantages G. disapproves of S. F. 147 despite the fact that according to Winterstein (*C. A.* 23, 3773) its effect in local anesthesia is 4 times higher than that of novocaine. G. Schwoch

The effect of yohimbine on the blood sugar and on the hyperglucemia and glucosuria produced by sympathetic poisons. Tetuzô Imahasi. *Okayama-Igakkai-Zasshi* 40, 1149–50; *Chem. Zentr.* 1929, II, 1313.—Yohimbine in small doses has no noteworthy effect on the blood sugar; in larger doses it produces a slight hyperglucemia. It inhibits almost completely the hyperglucemia and glucosuria produced by adrenaline. The hyperglucemia produced by diuretin, which probably is of central origin, is not influenced. Also the hyperglucemia produced by glucose infusion and Ca administration is not affected. Yohimbine inhibits the diuresis following the administration of diuretin and glucose. Thus to some extent its action is similar to that of ergotamine. G. Schwoch

Further studies on the action of yohimbine on the blood sugar. Tetuzô Imahasi. *Okayama-Igakkai-Zasshi* 40, 1347–8; *Chem. Zentr.* 1929, II, 1313; cf. preceding abstr.—In studying the action of yohimbine with respect to other forms of hyperglucemia in rabbits it was found that the hyperglucemia produced by pilocarpine, nicotine and diabetic puncture is distinctly reduced. The action of insulin is intensified. In the dog the normal blood sugar is distinctly reduced by yohimbine, while its action is weaker in the pancreatectomized dog. The hyperglucemia induced by large doses of yohimbine is not of central origin, since it also occurs after splanchnectomy. G. Schwoch

The influence of some drugs on fatal poisoning by tetrodotoxin. Tetuzô Imahasi. *Okayama-Igakkai-Zasshi* 40, 2464; *Chem. Zentr.* 1929, II, 1321.—Tetrodotoxin (fugu poison) exerts its toxic action on the central nervous system and on the peripheral motor app. The central action is intensified by picrotoxin, physostigmine, guanidine and adrenaline. It is very little inhibited by caffeine, xestetone and coramine. Lobeline and glucose have the best antidotal effect; cardiazole and glucose are effective to a lesser degree. G. Schwoch

Amino alcohols. III. The potentiation of the pressor action of adrenaline by arylpropanolamines. James C. Munch and Walter H. Hartung. *J. Am. Pharm. Assoc.* 19, 356–61(1930); cf. *C. A.* 24, 4773.—Medium-sized dogs anesthetized with morphine and chloretone were used. The effects of ephedrine and its homologs upon the subsequent pressor effects of adrenaline were studied. Phenylpropanolamine, its *p*-hydroxy and *p*-methyl derivs. and methylamino deriv. (ephedrine) given intrave-

nously to dogs in doses of 1–3 mg. per kg. potentiate the pressor action of adrenaline. Homologous amino alcs. in which the aliphatic side chain is decreased or increased do not show this potentiation. The degree of potentiation varies with the dose administered. Doses between 1 and 3 mg. per kg. doubled the action of adrenaline. Oral administration in doses which do not increase the blood pressure does not show any potentiating action. Because of this potentiation, caution is necessary in the administration of adrenaline following these products. L. E. WARREN

The influence of magnesium sulfate on the secretory activity of the digestive glands. I. On the gastric, intestinal and pancreatic secretions. W. HORSLEY GANTT AND GEO. V. VOLBORTH. *Am. J. Med. Sci.* 179, 375–80(1930).—A 30% soln. of $MgSO_4$ acts in the stomach as a mild irritant, producing a very small flow, which is usually alk. In a few expts. with the pancreatic secretion there was a slight increase in the pancreatic juice which began immediately after giving the $MgSO_4$ through the stomach tube. There was a copious secretion of the intestinal glands all along the small intestine, produced by the local contact of $MgSO_4$ with isolated loops of intestine. This occurred in the upper and lower duodenum and in the ileum and jejunum. **II. On the biliary secretion.** W. HORSLEY GANTT. *Ibid* 1, 380–5.—Results of other workers were confirmed, a flow of bile often coming from both the biliary passages and gall bladder after $MgSO_4$ was introduced through a stomach tube. When $MgSO_4$ was put directly into the duodenum bile was rarely produced and there was never any increase in the gall bladder pressure. R. C. WILLSON

Electrocardiographic study of the vagotropic action of adrenaline injected intravenously. M. PETZETAKIS AND VLACHLIS. *Arch. mal. coeur* 23, 333(1930); *J. Am. Med. Assoc.* 95, 828.—Results indicate that while adrenaline is amphotropic it possesses a predominant vagotropic action; verification was made by jugular tracings. Electrocardiographic study indicated a slowing of the cardiac rhythm accompanied by atrioventricular dissocn. R. C. WILLSON

The reaction of the central nervous system to experimental urea intoxications. BERNARD J. ALPERS. *Arch. Neurol. & Psychiat.* 24, 492–508(1930).—Doses of 1–2 g. urea were injected subcutaneously daily until the total dosage reached 16.25–37.25 g. urea; in 1 instance the dosage was 53.25 g. Deep intoxication resulted but more profound effects followed the intravenous injection of urea and human urine. The animals reacted in different ways, some exhibiting loss of appetite and wt. after small doses and others resisting large doses. Three of eight rabbits showed mild changes in the nervous system and one gave evidence of a severe intoxication. In these cases the cerebral white matter was more severely injured than the gray. R. C. WILLSON

The blood electrolyte changes in narcosis, with special references to calcium and potassium. S. KATZENELBOGEN. *Arch. Neurol. & Psychiat.* 24, 525–41(1930).—The blood chemistry was studied in rabbits during narcosis by ether and by diallylbarbituric acid. The CO_2-combining power of the plasma was increased in 5 of 10 expts and in 2 of 10 controls. Inorg. P decreased in 6 of 10 expts. and in 3 of 10 controls. Mg content followed closely the changes in P content, there being a decrease in 6 of 10 expts. and in 2 of 10 controls. K was decreased in 70.6% as compared with a decrease in 34.9% of the controls. An increase was observed in K in 9.8% and no marked change in 17.6%. Ca decreased in 55 of 58 expts., the decrease being within the limits of exptl. error in 3 instances; no change was found in 3. R. C. WILLSON

Investigations on synthetic ephedrine, with regard to antagonistic action toward insulin. A. BREMS AND C. HOLTEN. *Bibliotek for Laeger* 122, 137(1930); *J. Am. Med. Assoc.* 95, 312.—Synthetic ephedrine (equal parts of active and of inactive ephedrine) in nontoxic doses has no definite effect on the fasting blood sugar in normal and in diabetic persons, but after injections of insulin it retards the fall of the blood sugar; the effect is weak or uncertain where the fall of blood sugar is slight and considerable where it is marked. The oral administration of 2 mg. of synthetic ephedrine per kg. is always followed in normal persons by a protracted rise in the systolic blood pressure of 20 to 30 mm. Hg, while the diastolic pressure, pulse rate and respiration are practically unchanged. This dose is followed by const. leucopenia, relative neutropenia and lymphocytosis. R. C. WILLSON

Phosphate elimination in urine in normal and in diabetic persons after administration of insulin. S. GØRTZ. *Bibliotek for Laeger* 122, 159–97(1930); *J. Am. Med. Assoc.* 95, 382.—Phosphate elimination in the urine was decreased after a subcutaneous injection of insulin; there was also a decrease in the titrable acidity and in several cases the elimination of NH_3. In diabetic persons with acidosis there may be a marked increase in the 24-hr. phosphate elimination, which disappears with the administration of insulin. R. C. WILLSON

Response of blood guanidine base concentration in normal individuals and in patients with liver injury to the ingestion of methylguanidine sulfate. READ McL. ELLSWORTH. *Bull. Johns Hopkins Hosp.* **47**, 106–12(1930); cf. *C. A.* **24**, 3272.—The administration of 200 mg. methylguanidine sulfate by mouth did not produce in normal individuals a rise of blood guanidine base concn. in 4 hrs. In 8 cases of diffuse liver injury, the initial blood guanidine base was slightly elevated and ingestion of this amt. of guanidine salt produced a conspicuous rise of the blood guanidine.
R. C. WILLSON

The effect of intravenous injections of insulin. T. E. HESS THAYSEN. *Hospitalstudende* **73**, 357–71(1930); *J. Am. Med. Assoc.* **95**, 461.—After intravenous injection of insulin in 21 diabetics, the blood sugar curve was normal in the mildest cases, and the graver the case, the more abnormal was the blood sugar curve. R. C. W.

The action of electrolytes on the heart. JOHN FIDDES, H. LAWRENCE STOKES AND S. E. ALLISON. *Med. J. Australia* **1**, 835–40(1930).—The hearts of guinea pigs and rabbits, freshly killed, were immersed in Ringer's soln. With a $CaCl_2$ concn. of 0.04% the rate of beat was 84; with 0.01% it decreased to 78. The duration of the individual beat was practically the same, but the amplitude was decreased to less than one-half in the weaker soln. When the Ca was increased to 0.1% the heart beat became more and more tonic and tended to stop in the contracted state or semisystole Strong KCl (0.1%) slowed the heart considerably and caused auriculoventricular block When the perfusion was changed to 0.01% the heart rate was increased, block removed and beat strengthened. The p_H of the infusion was gradually changed from p_H 6.5 to 7.8. The amplitude was less, the duration of the beat less or unchanged in the acid perfusion; the interval between beats was longer. At p_H 6.5 complete block set in, the ventricle beating slowly with its own rhythm. R. C. WILLSON

Reactions of the liver to carbon tetrachloride. A. M. LACQUET. *Proc. Staff Meetings Mayo Clinic* **5**, 215–6(1930).—One injection of 0.25 cc. CCl_4 given by stomach tube to a normal rat produced central necrosis and fatty degeneration of the liver. The maximal lesion was reached after 24 hrs. and the liver was completely regenerated after 2 weeks. Repeated injections induced typical cirrhosis. R. C. WILLSON

The response of explanted embryonic cardiac tissue to adrenaline and acetocholine. CECILE MARKOWITZ. *Proc. Staff Meetings Mayo Clinic* **5**, 241(1930).—The excised hearts of embryo chickens were either studied in Locke's soln. or explanted according to the method of Carrel and Maxinow. Adrenaline and acetocholine exerted their typical effect on embryos 6 days old and older. The action of the drugs became less as the age of the embryo decreased. R. C. WILLSON

Action of bile salts on development of icteric bradycardia. E. THOMAS. *Rev. Med. Suisse Romande* **50**, 207–12(1930); *J. Am. Med. Assoc.* **95**, 164.—From rabbit studies it is concluded that neither alone nor in combination does Na glycocholate or Na taurocholate influence the rhythm of cardiac contraction. This is also true of the total ext. of bile, although a concn of 10% is lethal. R. C. WILLSON

The examination of cresyl-bearing extracts of ginger (VALAER) **17**. The formation and the constitution of Pb-Na thiosulfate (ODDO, MINGOIA) **6**. Synthesis of isoindenoquinolines (CLEMO, JOHNSON) **10**.

Chemical stimulation by alcohols in the barnacle, the frog and Planaria. WM. H. COLE AND J. B. ALLISON. *J. Gen. Physiol.* **14**, 71–86(1930).—Methanol, ethanol, propanol and butanol were tested for stimulating efficiency upon the barnacle (*Balanus tintinabulum*), the frog (*Rana pipiens*) and *Planaria dorotocephala*. Concns. of the successive alcs. in the series necessary to produce given stimulating effects followed the geometrical series, $1 : a^{-1} : a^{-2} : a^{-3} : a^{-4} : \ldots\ldots$, a representing some real no. In the frog and *Planaria*, the relationship between the log. of the concn. necessary to produce a given effect and the reciprocal of the reaction time is, within certain limits, linear. The concn. effect may be expressed by an equation which contains 2 consts., one characteristic of the alc. series, the other characteristic of the process of stimulation by alc. in any animal.

The ratio of the latter const. for successive alcs. represents a in the above geometrical series. Stimulation by alcs. in these expts. is due to energy changes at the receptive surfaces brought about by a definite orientation of the resp. alc. mols. Increase in stimulating efficiency as the no. of CH_2 groups increases is probably due to the action of the non-polar portion of the alc. mol. as the polar group remains practically const. throughout the series. In homologous series of org. compds. stimulating effects will be produced either by the polar or non-polar group depending upon which one becomes dominant in effect or to a combination of the two. C. H. RICHARDSON

12—FOODS

F. C. BLANCK AND H. A. LEPPER

The danger of demineralization of food. T. LANG. *Schweiz. Med. Wochschr.* **8**, 219-23(1930); *Bull. Hyg.* **5**, 612.—L. detd. the mineral content when vegetables were cooked in 1% salt soln. Ninety-three % of the K was lost, but the Na content was increased, in one case nearly 23 times as much. The Ca content was very much greater when cooked in the salt soln. than when H_2O was used. Cooking in 15% salt prevents the loss of minerals. GEORGE R. GREENBANK

"Blown tins" in the canned food industry. HENRI CHEFTEL. *Chimie & industrie* **24**, 544-8(1930).—A review of the various causes of "blown tins" and of the methods used for testing the liability to "blowing" of canned foods. Bibliography of 18 references. A. PAPINEAU-COUTURE

Methylene blue in tinned peas. DOUGLAS HENVILLE. *Analyst* **55**, 629(1930).—A note on the use of this dyestuff in Belgian "Green Peas." W. T. H.

Wheat protein test digestion studies. CLAUDE F. DAVIS. *Cereal Chemistry* **7**, 518-25(1930).—With extra-high heat for protein digestion, precautions should be taken in increasing the initial sulfate concn. of the digest, to speed up the time of digestion, especially with the Gunning method. With extra-high heat the Kjeldahl method gives a more stable condition for the NH_3 residue than the Gunning method in high sulfate concn. With extra-high heat and approx. the highest safe initial sulfate concn. protein digestion by the Kjeldahl method is 15 to 20 min. faster than by the Gunning method. L. H. BAILEY

The gluten and non-gluten proteins. M. J. BLISH. *Cereal Chemistry* **7**, 421-7(1930).—Flours vary not only in the amt. of protein but in the compn. of protein. Differences in compn. are probably due to variations in the distribution of the individual proteins and to the varying proportions in which they occur. The ratio of non-gluten to gluten protein appears to be the chief basis of variation. Of the several individual proteins occurring in wheat flour, gliadin is the only one whose chem. individuality has been established with any degree of certainty. Its ratio to the total protein appears to be fairly const. in most flours. Aside from gliadin, there are probably several other proteins, as suggested by the work of Osborne. However, there is strong evidence for the belief that these proteins have not yet been reliably identified or characterized. Trustworthy and dependable methods for the identification and quant. sepn. of individual flour proteins other than gliadin are not available. It is possible to demonstrate strong tendencies toward certain types of chem. constitution and properties, but beyond this the evidence is uncertain and indefinite. L. H. BAILEY

Studies on the qualities of combined wheats as affected by type of bin, moisture and temperature conditions. I. F. C. FENTON AND C. O. SWANSON. *Cereal Chemistry* 7, 428-48(1930).—Probably 1/2 of the wheat in the Southwest (U. S. A.) is now harvested by means of the combine. How to store this wheat so it will keep sound and free from damage until it is milled into flour is a big problem. These studies were undertaken to help solve this problem. Eleven bins each of approx. 500 bu. capacity were used. They were built of concrete, wood and steel, and of different shapes, *i. e.*, square and circular. Some were waterproofed both inside and out, others only on the outer surface. The ventilation was also different in different bins. Elec. resistance thermometers were installed in each bin to indicate temps. during storage. Observations of moisture content of wheat were made as it ripened and during harvesting. Some of the wheat became so warm during storage that it was necessary to move it to another bin to avoid serious damage. The grain was judged for market damage, rancidity and germination. Moving the wheat to prevent serious damage or total damage, when it became too warm, proved quite effective. As a rule the lower the moisture content of the wheat the less rancidity. High rancidity generally developed when the

moisture content was 15% and above. Rancidity also seemed to result from heating. High rancidity was also assocd. with poor baking results. L. H. BAILEY

Variation in properties of acetone extracts of common and durum wheat flours—A preliminary report. A. W. WALDE AND C. E. MANGELS. *Cereal Chemistry* 7, 480–6 (1930).—The acetone exts. of wheat flour are comparatively low in P content. The durum ext. has a higher sapon. no. and ester no. than the common wheat ext. Both exts. show, to some extent, the properties of drying oils. The durum wheat ext. has the highest I no. A sterol is present in common wheat which is relatively insol. in acetone at low temps. L. H. BAILEY

Proteolysis in bread doughs. W. E. BROWNLEE AND C. H. BAILEY. *Cereal Chemistry* 7, 487–517(1930).—Fermentation of the doughs was inhibited at varying lengths of time up to 5 hrs. by freezing in a refrigerator at $-17 \pm °$. The frozen doughs were then ground to a fine powder for further manipulation. Doughs which have been frozen, as above, were dehydrated with acetone, dried and ground to the fineness of flour. Comparisons were made between freshly mixed doughs prepd. by the freezing method and the original flours as to the amt. of total protein peptized by 3 saline solns. Standard patent flour dough and the same flour behave almost identically on such treatment while clear flour dough and the same flour behave differently. Saline soln. peptization of doughs fermented varying lengths of time indicated no change in the proteins as fermentation progressed. Distd. water and buffer soln. peptization demonstrate the effect of H-ion concn. on the peptization of flour proteins. Acetone dehydration does not affect the proteins as the same results were obtained from acetone-dehydrated doughs as from frozen doughs. Addn. of small quantities of proteases effects no change in peptization of dough proteins with salt solns. $SnCl_2$ pptns. of the true proteins reveal no proteolysis during fermentation of an ordinary bread dough, but show slight cleavage of the gluten proteins in doughs to which Diamalt is added. Cu sulfate ppts. more protein material than $SnCl_2$ but does not reveal any proteolysis during fermentation of an ordinary bread dough. Substantial changes in doughs to which pepsin was added were revealed by this method. Alc. pptn. of the proteins in a water ext. yields a ppt. low in N content and this fraction is not altered by fermentation. The N fractions sepd. by Hausmann's method are not altered by ordinary dough fermentation of 5 hrs. Viscometric methods demonstrate changes in fermenting doughs but the method needs considerable standardization before it can be of any use in studying proteolysis in bread doughs. A pptn. of the native proteins with trichloroacetic acid and of the proteoses by Na sulfate reveal no changes in the gluten proteins with fermentation. Fermentation does not affect the chem. structure of the gluten proteins so far as can be detected by any methods used in this study. L. H. BAILEY

A method for testing for ropiness of bread. H. H. BUNZELL AND MARION FORBES. *Cereal Chemistry* 7, 465–72(1930).—Rope, an infection of bread by *B. mesentericus* whose spores survive baking temp., has long been a dread of the baking industry. Bread infected by this organism will, on hot damp summer days, develop a soft, sticky, clammy crumb, having a yellowish discoloration. These symptoms develop in 36–72 hrs. B. and F. have developed a method to det. with a fair degree of accuracy the extent to which active rope organisms are present in bread. Catalase is an enzyme present in certain animal tissues and more generally in plant tissues, capable of bringing about the rapid decompn. of H_2O_2 to water and O. The catalase activity may be measured by detg. the change in pressure as a result of liberated O. Illustrations are shown of the app., used in the authors' method, for detg. this increased pressure. While the enzyme catalase may be present in numerous microörganisms, it is believed that *B. mesentericus* or allied organisms are the only ones present which under practical conditions will survive baking temps. Hence, by detg. the catalase activity the authors believe that they have a reliable index of the presence of the organisms responsible for the development of rope. L. H. BAILEY

The A. O. A. C. gasometric method for the determination of carbon dioxide in baking powder. J. R. CHITTICK, F. L. DUNLAP AND G. D. RICHARDS. *Cereal Chemistry* 7, 473–80(1930).—The A. O. A. C. official gasometric method for baking powder gives remarkably concordant results in the hands of different operators, and results which are very closely in agreement with the actual total CO_2 present. The assertions of Hertwig and Hicks that a correction for vapor tension must be applied is not borne out by these authors' results. Whatever vapor tension effect is produced by the liquid in the reaction flask is closely compensated for (in those working temps. generally experienced in the lab.) by the CO_2 dissolved in the liquid. L. H. BAILEY

Freshness of milk. K. L. PESCH AND U. SIMMERT. *Milchwirtschaft. Forsch.* 8, 551–75(1929).—An indicator for the detn. of p_H is described. Reasurin is added to

milk, which is held at 20°; the longer the time of reduction to a red color the greater is the freedom from bacteria. GEORGE R. GREENBANK

Mobile milk laboratories. THOMAS PARRAN. *Am. J. Pub. Health* **20**, 1219–20 (1930). J. A. KENNEDY

Pasteurization of milk without cooling in India. C. E. MACGUCKIN. *J. Central Bur. Animal Husbandry & Dairying India* **3**, 67–75(1929).—Pasteurization by the holding method without cooling is a thoroughly practical, beneficial, economical and reliable method of handling milk in India, provided the factors necessary for success are strictly carried out. K. D. JACOB

A practical method for fat determination in milk. BALWANT SINGH. *J. Central Bur. Animal Husbandry & Dairying India* **3**, 76(1929).—The method previously described (*C. A.* **23**, 5514) is modified as follows: To 17.6 cc. of milk contained in a Babcock bottle add 5 cc. of Fehling soln. and 2 cc. of a mixt. of 4 parts of MeOH and 1 part of AmOH. Place the bottle in water at 80° and shake thoroughly every min. until the liquid is red. Finally, shake vigorously and allow the bottle to stand in the bath for 3 min. longer. Then add hot water slowly till the fat column rises sufficiently in the neck of the flask to be read. Twirl the bottle in the palms of the hand to disentangle any fat globules from the soln. below. The bottle should be cooled somewhat before the percentage of fat is read off. K. D. JACOB

Further work on the refractometer in milk analysis. G. D. ELSDON. *Analyst* **55**, 618–25(1930).—As the result of considerable comparative work, which is described, the conclusion is drawn that the $CuSO_4$ method of producing milk serum is, on the whole, as useful as any that has been devised. It is true that the milk must be fresh. The phosphotungstic acid method has the advantage that no rise in refraction occurs in the early stages of souring but the removal of the albumin results in a lowering of the value obtained, which may be a disadvantage. When the sour serum method is used, the souring should be carried out at a uniform temp. and the refraction should be taken as soon after complete clotting as possible. A list of further references to the use of the refractometer in milk analysis is given. W. T. H.

Viscosity of milk and milk products. W. MOHR AND F. OLDENBURG. *Milchwirtschaft. Forsch.* **8**, 429–61, 576–92(1929).—A study is made of different forms of viscometers, in which considerable variation is found. The authors prefer the Lawaczeck. Detns. were made with milk having acidity occurring naturally and that resulting from added acid. GEORGE R. GREENBANK

Determination of chlorine and sugar in small quantities of milk. F. MUNCHBERG. *Milchwirtschaft. Zentr.* **59**, 161–3(1930).—Cl is detd. by heating 1 cc. of the sample to boiling with 2 cc. of halogen-free HNO_3 (d. 1.40) and 1 cc. of 0.1 *N* $AgNO_3$ or 5 cc. of 0.02 *N* $AgNO_3$. A 10% soln. of $KMnO_4$ is added to the boiling liquid until it clears. The liquid is cooled by the addn. of 30 cc. of distd. water and the excess Ag titrated with 0.02 *N* NH_4CNS. The addn. of 0.5 cc. of satd. Fe NH_4 alum soln. before titration provides an indicator. Sugar is detd. by adding 1 cc. of 20% CCl_3COOH to 10 cc. of the sample, shaken well and filtered through a dry filter. The rotation observed by a Zeiss polarimeter multiplied by 2.2 gives the percentage of sugar. The results are lower than those given by the iodometric methods of detg. sugar. G. R. G.

The catalase of milk. I. Determination of milk catalase by potassium permanganate titration. I. ZAVKOVSKII AND P. ALEKSEEV. *Fermentforschung* **12**, 55–66 (1930).—In the detn. of the catalase content of milk by various forms of app. in which the vol. of liberated O is measured, the values obtained vary within rather wide limits and are not comparable with each other. The detn. can be made, however, with rapidity, convenience and great accuracy by the $KMnO_4$ titration method, as follows: To 2 cc. of fresh milk add 98 cc. H_2O and 5 cc. of 0.3% H_2O_2, mix thoroughly and allow to stand 30 min. at room temp. A 2nd sample of the same milk which has been boiled and cooled is given the same treatment for the blank detn. After 30 min. add to each mixt. 5 cc. of 10% H_2SO_4 and titrate with 0.1 *N* $KMnO_4$, until the rose color persists for 15 sec. A fading of the color after a longer time is not due to the action of $KMnO_4$ on H_2O_2 but to oxidation of other constituents of the milk. After deduction of the blank the catalase value of the milk may be expressed in mg. of O per 100 cc. On account of the inaccuracy of the gasometric method, the catalase values reported in previous investigations need revision. A. W. DOX

Alkali number of the ash of cow milk with special reference to fodder and lactation period. A. SCHNECK AND B. GORGEL. *Milchwirtschaft. Zentr.* **59**, 49–53, 65–70, 81–85, 97–101(1930).—There has been considerable variation in the analysis of the constituents of milk ash, especially the Na value. The alkali no. K_2O/Na_2O has been given anywhere from 3.85 to 13.02%. Earlier values range from 2 to 4, but more recent work

by Nottbohm (*C. A.* **23**, 4509) gives an av. value of 6 with a max. value of 10. This value was detd. on milk from stall-fed cows receiving special diets which had low, normal and high mineral values. The authors use the perchlorate method throughout which gives results in good agreement with those given by the platinichloride method. Mixed milk from 10 cows gave 2.2–2.4; colostral milk gave 1.2–1.5 and had a low K value. The Ca values for different animals varied considerably, in one case being 25–30% above the av. Studies on one cow during lactation showed normal compn. after 4 days with a gradual decrease in K as the lactation period progressed. Dosing with carbonates of Na, K and Ca showed nothing of value. No change in the Ca content was observed during lactation. GEORGE R. GREENBANK

Kohn's method of distinguishing pure cow milk from pure goat milk. A. JANOSCHEK. *Z. Fleisch. Milchhyg.* **40**, 93–5(1929).—The method consists of a comparison of the rate of soln. of the pptd. casein in H_2SO_4. The acid ppts. the casein of the goat milk in a finer state of division and it dissolves more rapidly. The method has been found reliable for fresh untreated milks, but cannot be applied to sour milk or to sour milk neutralized by soda, or to milk preserved by HCHO. GEORGE R. GREENBANK

The fluctuation of p_H in koumiss from mare's milk. Changes in the specific gravity and in the quantity of fat and amino nitrogen in koumiss. K. S. ARKHIPOV. *Arkh. Biol. Nauk* **30**, 475–85(1930).—"The p_H of the koumiss from mare's milk fluctuates between 4.3 and 3.4 according to the temp. and the duration of keeping. Adding 5% of Na_2CO_3 affects the p_H. The quantity of amino N fluctuates between 0.084% in strong koumiss or leaven and 0.064% in weak koumiss, according to the temp. and the duration of fermentation. The sp. gr. of the leaven fluctuates from 1.005 to 1.007; the sp. gr. of a non-fermented mixt. of milk and leaven is 1.020–1.016; the sp. gr. of a mixt. that had fermented for 24 hours at a temp. of 10° (weak koumiss) is 1.015–1.011, and of a mixt. that had fermented for 48 hrs. at the same temp. is 1.005–1.007. The quantity of fat in koumiss varies according to the quantity of fat in the milk and according to the duration of fermentation of the koumiss." W. A. PERLZWEIG

The effect of some oil cakes on milk secretion. N. S. AYYANGAR, CHOUDHURY KARM RASUL, S. KARTAR SINGH, D. B. KOLHE AND LALCHAND SIKKA. *J. Central Bur. Animal Husbandry & Dairying India* **3**, 77–91(1929).—In the first expt., linseed cake, country coconut cake and expeller coconut cake were compared. Linseed cake appeared to produce a slightly larger vol. of milk than either coconut cake, but the increase in vol. was due only to diln., the milk from cows fed on coconut cake being distinctly richer in fat. There was no pronounced difference in milk from cows fed on the 2 varieties of coconut cake. In the second expt., linseed cake, peanut cake and cottonseed cake were compared. Peanut cake and cottonseed cake produced equal amts. of milk, both being slightly superior to linseed cake. Cottonseed cake was slightly superior to the other cakes in fat production, and produced milk contg. consistently higher percentages of N. II. AJEET SINGH GILL, ALAM SINGH, A. GOPALAKRISHNAYYA NAIDU AND AYANNA KELAPANDA. *Ibid* **4**, 7–22(1930).—Results previously obtained were confirmed. K. D. JACOB

Xylene value of adulterated butter. E. HANKE AND F. DEUTSCHMANN. *Milchwirtschaft. Forsch.* **8**, 525–32(1929).—The min. permissible value of pure butter is given as 18.0 when the van Raalte xylene test is used. GEORGE R. GREENBANK

Variations in the component fatty acids of butter due to changes in seasonal and feeding conditions. THOMAS P. HILDITCH AND JOHN J. SLEIGHTHOLME. *Biochem. J.* **24**, 1098–1113(1930); cf. *C. A.* **23**, 1963.—The influence of added fat in the diet of cows is of a minor order compared with that due to other causes. Profound changes in fatty acid composition appear to be caused by conditions such as the change from outdoor to indoor life, the general character of the diet, and seasonal changes in temp. BENJAMIN HARROW

The value of hydrogen-ion concentration in the study of cheese, especially Tilsiter cheese. M. SCHULTZ. *Molkerei Ztg.* (Hildesheim) **44**, 527–8(1930).—A quinhydrone method of detg. the p_H is described. The rind decreases in acidity until in old cheese it is almost neutral. For a complete study samples must be taken from different zones. Mild ripe Tilsiter gave a p_H of 5.2–5.6 in the center; at 5.7–5.82 at this zone it had a bitter taste. A review of the literature on p_H measurement, kinds of cheese and the errors involved in these measurements is included. GEORGE R. GREENBANK

Do fu: An oriental food. JOSEPH S. HEPBURN AND KEUM SUNG SOHN. *Am. J. Pharm.* **102**, 570(1930).—The oriental food, known as *do fu* in Chinese and as *doo pu* in Korean, is a soy bean prepn. The beans are soaked with twice their vol. of cold water for 24 hrs., then ground with the water. The resulting mass is filtered through a coarse linen bag. The white milky filtrate is heated in a vessel, with occasional stir-

ring, until it begins to foam. Then a satd. soln. of NaCl is added until coagulation is complete. The coagulated mass floats on the brine, is collected, placed in a linen bag and subjected to pressure with a light wt. for 2 or 3 hrs. to remove the adherent liquid. The resulting cake is kept in an ice box or in cold water. A sample of *do fu* was found to have the following percentage compn.: total solids 13.37, moisture 86.63, ether ext. 4.65, crude fiber none, crude protein 4.22, ash 0.59 and N-free extractives 3.91. W. G. GAESSLER

A new method for the preservation of fruit juices, sweet must, etc. A. MEHLITZ. *Konserven Ind.* **1930,** 306–7, 321–2.—The juice is centrifuged 5 min. at 3500 r. p. m., decanted, clarified by digestion at 45° with a strong enzymic ext. of *Aspergillus oryzae* and then run through an asbestos pre-filter, filtered through a Seitz E K germ filter and preserved aseptically. F. P. GRIFFITHS

The effect of heat on chocolate pastes in causing caramelization of their component sugars. RAOUL LECOQ. *J. pharm. chim.* [8], **11,** 522–9(1930).—From complete analyses of 4 grades of com. chocolate before and after being treated in a heated mixer, it is concluded that heating of chocolate pastes at temps. from 50° to 120° causes very pronounced "caramelization" (*A*) of sugars, manifesting itself in increased proportion of reducing sugars, chiefly at the expense of the initial sucrose content. *A* seems to depend on the length of treatment and the temp. It is produced to a lesser extent during the prepn. of com. brands requiring lower temps., but is especially evident in superheated "fondant" chocolates. The quantity of reducing sugars in terms of invert sugar may here exceed 25% of the initial sucrose. S. WALDBOTT

Role of fiber in poultry feeding. E. T. HALNAN. *Fertiliser, Feeding Stuffs & Farm Supplies J.* **15,** 559–60(1930).—Fowls cannot digest pure cellulose but can digest a certain portion of the fiber in various plant products, the percentage varying from 5 for wheat to 21 for white cabbage. Approx. 7% of the fiber in uncooked peas can be digested while the fiber in cooked peas is completely indigestible. Fiber depresses the digestibility of the N-free ext. but has no effect on the digestibility of the protein and fat. The chief value of fiber-contg. foods is their utilization for the purpose of regulating the vol. capacity of the ration, and so automatically fixing the wt. of food consumed daily by birds on a free food system. K. D. JACOB

Feeding experiments at Hosur, 1926, 1927 and 1928. F. J. WARTH. *Mem. Dept. Agr. India, Chem. Ser.* **11,** 53–72(1930).—From extensive digestion trials, the nutritive values of the typical spear grass products—prime hay, mature hay, early cut hay and silage—have been evaluated and the starch equiv. values of the feeding test rations detd. The early cut hay and silage were much more digestible than mature hay and gave much greater increases in the live wt. of animals. K. D. JACOB

The ground nut. S. D. TIMSON. *Rhodesia Agr. J.* **27,** 15–38(1930).—Analyses of peanut seeds, shells, vines and oil cake are tabulated. A. L. MEHRING

Soy bean extraction residues from different methods of treatment (MALKOMESIUS, SCHRAMM) **27.** The oil-bearing royal palm tree seed of the West Indies (HEIM DE BALSAC, *et al.*) **27.** Chinese tung oil seeds (ANON.) **26.** The physical chemistry of starch and bread making (KATZ) **2.** Antiseptics and food-preservatives (Brit. pat. 331,274) **17.**

Apparatus for heating and cooling foods, etc. EDGAR B. NICHOLS (to Pfaudler Co.). U. S. 1,780,794, Nov. 4. Structural features.

Apparatus (with specially constructed heating or cooling-coils) for treating foods, etc. EDGAR B. NICHOLS (to Pfaudler Co.). U. S. 1,778,810, Oct. 21. Structural features.

Apparatus for agitating the contents of containers such as foods, paints, etc. WM. H. BROOKS and WALTER PAGE. U. S. 1,780,333, Nov. 4. Structural features.

Apparatus of the "holding type" for pasteurizing milk, etc. C. O. HOLMBERG and C. A. LÖFGREN. Brit. 331,783, Oct. 12, 1929. Structural features.

Apparatus for evaporating and deodorizing milk, cream, etc. CHRIS M. PETERSON (to Ward Dry Milk Co.). U. S. 1,778,959, Oct. 21. Structural features of an app. for spraying the liquid into contact with heated tubes.

Timing device for cream testers. PAUL L. COOL and BUOL F. COOL (52% to Howard McDaniel). U. S. 1,780,377, Nov. 4.

Margarine. A. K. EPSTEIN. Brit. 331,562, Feb. 5, 1929. See U. S. 1,707,800 (*C. A.* **23,** 2510).

Regenerating used cooking fats and oils. MILLARD BRANDT (to Darco Corp.). U. S. 1,781,661, Nov. 11. A batch of the used material in the liquid state is percolated through a body of coarse-grained, highly activated, adsorbent carbon, which during

the percolation is maintained at a temp. near that of boiling water, and the carbon is then exposed to the air while at about the same temp. and then reused.

Lactic beverage. WILLARD J. SCHOLL (to Malt-O-Matic Corp.). U. S. 1,781,249, Nov. 11. A lactic beverage is prepd. which at a temp. below 0° is of creamy consistency and contains minute bubbles of air and minute particles of ice, the beverage having a d. of about 0.5.

Chocolate. EARL B. WORKING. U. S. 1,781,672, Nov. 11. A small proportion of lecithin is incorporated in a chocolate mass to prevent "graying."

Incorporating condiments with ground meats. HUGH E. ALLEN (one-half to Albert G. McCaleb). U. S. 1,781,154, Nov. 11. The meat is treated with a minor quantity of essential oils of spices and oleoresins of peppers and with a major quantity of "semi-pulverulent" sugar acting as a carrier.

Storing fruits and vegetables. E. MILANI. Brit. 332,209, Feb. 16, 1929. Fresh, ripe fruits and vegetables are sealed in a container in the presence of CO_2 or other inert gas and the container is minutely vented prior to or very soon after the product generates its own gas and begins to sweat. The vented container is preferably stored at a low temp. (suitably about 0°). Examples are given of the treatment of strawberries, apricots and pears.

Pectin preparations. A. LEO. Brit. 331,295, April 15, 1929. Pectin and sugar are so combined that subsequent soln. of the pectin in water or fruit juice precedes the soln. of the sugar, *e. g.*, sugar particles may be sprayed with a pectin soln. and the coating dried on them, and if desired this prepn. may be mixed with powd. citric acid or the like, the soln. of which may be retarded by a thin coating of paraffin. Various details and modifications of compns. and procedure are described.

Apparatus for drying fish meal, beets, etc., by heated air currents. WM. H. HASLAM. U. S. 1,779,470, Oct. 28. Structural features.

Dehydrating vegetable materials such as root or surface crops. BRYNAR J. OWEN (to Sugar Beet and Crop Driers, Ltd.). U. S. 1,781,473, Nov. 11. Heated air of relatively low humidity is passed through a mass of the material and the temp., pressure and rate of flow of the air are so coördinated with the mass of the material that exothermic reactions will take place in the material and will furnish part of the latent heat of vaporization necessary for the drying, and so that the total heat available will suffice to prevent condensation within the material but will be insufficient to afford any substantial degree of superheat to the vapor discharged from the material.

Use of dried seaweed as a preservative packing material, etc. FISADCO, LTD., and W. H. HASLAM. Brit. 331,546, April 2, 1929. Finely divided dried seaweed such as that prepd. as described in Brit. 303,591 (*C. A.* **23**, 4513) may be sprinkled over fish, meat, fruit, vegetables or hides or other materials as a preservative, packing or deodorant. Fish offal or excrement thus treated may be used as *fertilizer*.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

The relation between chemical industry and research. RICHARD WILLSTÄTTER. *Chem.-Ztg.* **54**, 793–5(1930). E. H.

Solvent recovery by absorption in *m*-cresol, silica gel and activated carbon. FRITZ OHL. *Kunstseide* **12**, 239–41(1930).—Absorption methods for the recovery of solvents depending on the use of *m*-cresol (I), silica gel (II) and activated C (A-Kohle) (III) are compared and discussed. Methods using I or II are the most important for the *rayon industry*. I possesses the disadvantage of forming a resin with the solvents, which decreases the efficiency as the absorption proceeds. This difficulty may be partially overcome by adding tetralin to I. II gives a very pure solvent. Its absorption capacity is much better at lower temps. (0°). One of its disadvantages is the high water content of the solvent recovered. With III an absorption temp. of 35–40° is required and a high steam consumption is needed to drive out the absorbed solvent. Also, the use of a protective gas is necessary since at ratios of 2–3% C dust or 4–5% solvent self ignition may occur. Another disadvantage of the C process is its property of forming by-products such as aldehyde, mesityl oxide and pyranton, which are sepd. only with difficulty from the alc. or acetone. The degree of purity of the recovered solvent amounts to only 60–75%. The recovery of aliphatic, halogen derivs. by the C method is unsatisfactory because of the formation of condensation products with the liberation of HCl. FREDERICK C. HAHN.

Uniform description of graded materials and the evaluation of their fineness. M. SPINDEL. *Tonind.-Ztg.* **54**, 1385–6, 1401–3(1930). For a given fineness modulus the surface areas of the aggregates are const. and any change in modulus on grinding gives a direct measure of the work performed. Proposal is made to set up a metric fineness modulus with sieve openings of 1, 10, 100, 1000 . . . . 10^5 microns as a basis and divide each range into 5 divisions, the log. of whose openings shall be 1.0, 1.2, 1.4, 1.6 . . . 5.0 which correspond to the fineness moduli of gradings of aggregate whose av. size corresponds to that sieve opening. This system can then be applied to *cement* and other fine materials. F. O. ANDEREGG

Carbon monoxide concentration in garages. A. S. LANGSDORF AND R. R. TUCKER. *Heating, Piping and Air Conditioning* **2**, 695–7(1930).—The air in a large closed-door garage in St. Louis, Mo., was sampled during a winter cold spell and analyzed for CO by the I_2O_5 method. The concns. of CO varied between 1.34 and 2.71 parts per 10,000, depending on the location in the building. The highest concn. was from the office. During this period the workmen suffered more or less discomfort especially when the temp. fell below the usual av. The highest concn. of CO permissible for exposure for any length of time is not more than 1 part in 10,000. J. W. SHIPLEY

Intoxications caused by a homolog of aniline in a fly-paper plant. B. ROSENTHAL-DEUSSEN. *Arch. Gewerbepath. Gewerbehyg.* **1**, 380–96(1930); *Chimie & industrie* **24**, 586.—R.-D. observed numerous cases of intoxication produced by a homolog of $PhNH_2$, the clinical symptoms being the same as those of intoxication by $PhNH_2$. Women are apparently more sensitive than men, and all the cases observed related to women. As intoxication was more frequent in winter (less ventilation) it is recommended to increase the ventilation, and also to maintain the temp. at about 12°. But the intoxications can be prevented entirely only by suppressing completely the use of the toxic compd. in the fly paper. A. PAPINEAU-COUTURE

Mode of action of sodium peroxide in the isolation gas mask canister. G. STAMPE AND E. HORN. *Z. ges. Schiess-Sprengstoffwes.* **25**, 419–22(1930).—The decompn. of the contents of the canister of the isolation gas mask is discussed in detail. It is shown that certain used, hydrated Na_2O_2 prepns. give off O spontaneously for a long time before reaching an equil. A. L. KIBLER

Merits of carbon dioxide as a refrigerant. F. P. MACNEIL. *Power* **72**, 653–4 (1930).—A total heat diagram for CO_2 is given and its practical use explained. D. B. DILL

Testing physical properties of materials by oscillations of flexure of test pieces. O. FÖPPL. Brit. 332,299, April 24, 1929. App. is described.

Testing the flammable conditions of gaseous mixtures containing hydrocarbons and oxygen. NORMAN J. THOMPSON. U. S. 1,779,569, Oct. 28. In testing mixts. such as air contg. volatile solvent vapor, a sample is continuously withdrawn from the mixt. and is subjected to continuous combustion, and the increase in temp. produced by the combustion serves to indicate the fractional proportion of the amount of heat produced by the combustion relatively to the const. amount of heat produced by continuous combustion of any hydrocarbon gases at the lower limit of explosive strength of the hydrocarbon gases with air. App. is described.

Column-still operation for fractional condensation and use of vapors for generating power. A. LOSEV, P. GOTTLIEB and L. L. HAUPT. Brit. 331,485, Dec. 11, 1928. Vapors such as those of hydrocarbon oils are successively passed through chambers of a fractional condensing column with intervening reciprocating engine and turbines for generating power and assisting in the condensation. Numerous structural details are described.

Purifying air containing cyanogen chloride. PAUL O. ROCKWELL. U. S. 1,781,664, Nov. 11. Moisture is removed from the air and assocd. toxic gases (suitably by $CaCl_2$) and the gas is then passed through dry, granular, inorg., alk. material such as active C and NaOH. The process may be carried out by use of canisters, details of which are described.

Gas-protective or breathing filter. HERMANN STELZNER (to Otto H. Dräger). U. S. 1,781,254, Nov. 11. Structural features.

Temperature indicator for refrigerators, etc. EDWARD S. HALSEY. U. S. 1,779,066, Oct. 21. Structural features.

Use of methylene chloride as a refrigerant. WILLIS H. CARRIER (to Carrier Engineering Corp.). U. S. 1,781,051, Nov. 11. Evapn., compression and condensation of the methylene chloride is effected under a pressure at all times not materially greater than atm. pressure, in order to prevent leakage. App. is described.

Apparatus for detecting ammonia gas in refrigerating plants, etc. LOUIS A. HAVENS, JR. U. S. 1,780,483, Nov. 4. Structural features.

Insulating wires for electrical machinery, etc. I. G. FARBENIND. A.-G. Brit. 331,203, March 18, 1929. Details are given of the production of coatings of resinous condensation products obtained from other dicarboxylic acids or thioether dicarboxylic acids and polyhydric alcs. as described in Brit. 327,722 (*C. A.* **24**, 5173).

Sheathing cables with lead. KABELFABRIK A.-G. Brit. 331,301, Feb. 7, 1929. Sheathed cable from a lead press is cooled by winding on a drum at least partially immersed in cold water.

Fiber board. ROGER W. CUTLER and JOSEPH R. COOLIDGE, 3RD (to Montan, Inc.). U. S. 1,779,532, Oct. 28. Air is forced under pressure into the microscopic cells and pores of unvulcanized fibrous material such as fiber board and while the air is still held in the material under pressure it is impregnated with a melted waxy material such as Montan wax which remains hard and brittle at high atm. temps. but is sufficiently fluid at a temp. of 120° to be forced into the pores and cells of the material; the imprisoned air is then permitted to expand and thereby eject a portion of the impregnating material, followed by cooling and hardening. The product is suitable for *elec. insulation*, etc.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

London water supply (Annual Report, 1929). ALEXANDER HOUSTON. *Surveyor* **78**, 169–70(1930).—The bad taste of water in some places was eliminated by addn. of NH_4 sulfate and Cl. Prefiltration of water increased bacterial quality 100 to 1000 fold. The value of chem. tests was emphasized. Hot-water drinkers object to cloudiness of the boiled water. H. suggests that the water be heated just to boiling.
A. L. ELDER

Surface water supply of Hawaii, July 1, 1925, to June 30, 1926. MAX H. CARSON, *et al.* *U. S. Geol. Survey Water-Supply Paper* **635**, 145 pp.(1930). E. H.

The water purification system of Helsingfors. ALBIN SKOG. *Tekn. Foren. i Finland Forhandl.* **50**, 177–81(1930).—The purification system is based on sedimentation with Al sulfate, followed by rapid sand filters. Eight filters of the Jewell type with a total area of 21 sq. m. are used. The sand depth is 105 cm. and the grain size 0.5 mm. which is supported by a 20 cm. layer of coarse sand. These are washed once per 24 hrs. for a period of 10–15 min. The hardness has been kept at about 2.0° on the German scale, particularly since electricity has supplanted steam as power for industrial purposes. The optimum alum requirements are 55–100 g. of 17% Al_2O_3 per cu. m. In the summer a settling period of 2.3–2.9 hrs. is required and in winter 4.5–5.7 hrs. An addnl. 2 hrs. settling period is required to reduce the bacterial count. The settling takes place in 3 basins in series which are cleaned once a month. Liquid Cl has been used since 1928. Chlorophenol tastes occasionally cause trouble but their origin has not yet been detd.
H. C. DUUS

Water purification in factory operation. FRITZ HOYER. *Chem.-Tech. Rundschau* **45**, 842, 862(1930).—Air-cleaned filters are used chiefly for factory and boiler-feed water purification and the series is so connected that single elements can be cleaned without interrupting filtration. Filters adapted for cleaning water under pressure have thin filter layers and can be cleaned in 20–40 sec. Settling basins are applicable for waters contaminated by heavy suspensions which sep. readily. These are operated more economically when the water enters in a slow stream. Coagulating agents such as alum may be added. Removal of Fe from water consists of aerating to produce flocculation, production of contact action and removal of flocculent material by filtering. Hardness is reduced by filtration through artificial zeolites or Permutit, which permits reduction of hardness in uncontrolled hard waters to zero. The prepn. and recovery of *Permutit* after use are discussed. Dissolved gases are removed from boiler-feed waters by heating to reduce their soly. or by vacuum treatment in the cold.
E. PICKERING

Water purification with aluminum sulfate. W. PRANN. *Chem.-Tech. Rundschau* **45**, 881(1930).—The choice of coagulating agents for water purification prior to filtration requires exact investigation of the water if alkalies or Fe salts are to be used. The best coagulant is tech. $Al_2(SO_4)_3.18H_2O$. This is strongly hydrolyzed in aq. soln. with the pptn. of $Al(OH)_3$, and has an acid reaction. Its soly. in water between 0 and 100° is given. The amt. used should vary between 20 and 80 mg. per l. depending

on the character of the water. Alkali may be added soon or immediately after the $Al_2(SO_4)_3$. After settling the water is run through a gravel filter. E. PICKERING

Phenolphthalin and pyrocatechol-*o*-carboxylic acid reactions for the determination of the "activity" of mineral waters. L. FRESENIUS AND H. LEDERER. *Biochem. Z.* 226, 139–46(1930).—The reactions by these reagents in no manner indicate that the inorg. components of natural mineral waters are in a specially "active" condition, as these reactions are also obtained with artificial waters. S. MORGULIS

The salinity of the water of the bay of Palmo de Malorka in 1929 and new data on densimetry of ocean water. FRANCISCO DE P. NAVARRO AND FRUTOS A. GILA. *Inst. Espan. Oceanografia. Notas y Resúmenes*, Ser. 2, No. 44, 28 pp.(1930).—Assuming that the tables of Knüdsen are valid for oceanographic work and for work in marine biology, N. and G. propose to det. the salinity and density of sea water "in situ" by taking refractometric observations at 0°, instead of using the chlorovolumetric method. In conducting the studies of the salinity and densities of the water throughout the bay samples were taken through the year at different depths and detns. made. It is concluded that variations in the density of the bay water depend more upon temp. than upon salinity. Some cases of abnormal stratification were observed where the density of the upper layers was greater than that of the lower, although the difference seldom reached the fourth decimal. These cases of abnormal stratification are characteristic of homogeneous water and are due equally to factors of temp. and a salinity contributing to the production of the phenomenon of "sea calmness." B. S. LEVINE

Further studies on the thermophilic digestion of sewage solids. H. HEUKELEKIAN. *Sewage Works J.* 2, 219–27(1930).—Studies of the influence of temp., seeding and reaction control on the thermophilic digestion of fresh sewage solids indicate that liming accelerates decompn. and makes possible a reduction in the quantity of seeding material without prolonging the period of digestion; seeded mixts. can be digested in 12–14 days and if limed the amt. of seeding material may be reduced or the load of fresh solids may be increased without materially retarding digestion; the digestion of solids without seeding sludge requires about 25 days if the p_H values of the solids are controlled so as not to drop below 7.0; digestion is somewhat more rapid at 55–60° than at 45–55°. Above 60° the digestion is retarded; gas yield per g. raw volatile matter added, volatile matter reduction and decompn. of nitrogenous substances are greater under thermophilic conditions than at lower temps.; solids concentrate to a higher extent at high temps. than at lower. E. HURWITZ

Factors in sludge digestion. MARSHALL LUNDIE. *Surveyor* 78, 165–7(1930).—Results of investigations at Pretoria, South Africa, are reported. The optimum temp. for sludge digestion is about 27°. Most rapid digestion is obtained if fresh solids are seeded before acidity develops. Material contg. 18% solids digested most rapidly. It was found unnecessary completely to digest sewage sludge to produce an inoffensive sludge. Ash contents of raw sludge, partially digested sludge, and fully digested sludge were 19.6, 31 and 42–46%, resp. A. L. ELDER

Observations on two-stage sludge digestion. A. M. BUSWELL, G. E. SYMONS AND E. L. PEARSON. *Sewage Works J.* 2, 215–8(1930).—Observations made during the study of the effect of two-stage sludge digestion showed that fermentation is very rapid at first. It results in the decompn. of the simpler compds. and the production of a large quantity of gas. After fermentation is complete the sludge undergoes a ripening process during which it loses its water-binding properties. It is suggested that a complete digestion process can best be carried out in a sep. sludge digestion tank consisting of a relatively small primary tank designed to allow 6 to 8 days detention and equipped with devices to prevent scum and foam formation, followed by a secondary tank of sufficient size to permit the necessary ripening to a state where it will drain on sand beds. Such a design would result in economies in construction and operation. E. H.

Field experiments on the digestion of sewage sludge at Baltimore. C. E. KEEFER AND W. RUDOLFS. *Sewage Works J.* 2, 199–213(1930).—These expts. dealt with the effect of reaction control on the rate of sludge digestion. Daily charges of previously settled sewage solids, having a p_H of about 5.0, were added to an uninsulated, unheated sep. sludge digestion tank. The results of the expt. indicate that by raising the p_H from approx. 5.1 to 7.3 a much larger amt. of material can be digested in a given time. Sludge which had not been adjusted to proper p_H and which had not been seeded did not digest even over a period of time as long as 850 days. E. HURWITZ

The oxygen requirements of the activated [illegible]

AND E. W. [illegible]

of absorption of O by activated sludge, in the amts. and periods of aeration commonly used, is fairly uniform, and varies directly in proportion to the weight of the sludge; (2) the rate of absorption of O varies, further, in proportion to the content of org. matter in the sludge; (3) the rate of absorption of O by activated sludge from the North Side Treatment Works of the Sanitary District of Chicago averaged approx. 7.0 mg. of O per g. of sludge per hr.; (4) mixts. of sewage plus sludge absorb O in proportion to the weight of sludge, but with increasing amts. of sludge most of the O-demanding material is coagulated or adsorbed by the sludge so that very little O is required for the unadsorbed material in colloidal or true soln. The subsequent rate of oxidation of the coagulated material in the sludge is slow and comparatively uniform. The sludge passes through many cycles of aeration before it is removed, and during these successive aerations the org. matter is slowly oxidized; (5) based on the reduction of biochem. O demand the results obtained do not indicate that the period of aeration and amt. of sludge vary inversely, as has been claimed. Small quantities of sludge reduce the biochem. O demand of sewage as rapidly as large amts. Reaeration of sludge is indicated, however, when small quantities are used because of the shorter period of retention; (6) adjustment of the rate of air supply should be governed by the amt. of sludge in the aeration tanks. With large amts. a fairly uniform rate is desirable. Rates of aeration in proportion to the biochem. O demand of sewage, as has been recommended by some investigators, are greatly modified by the O requirements of the sludge. E. H.

Purification of sewage by the activated sludge process. Results obtained with Oviedo sewage in a laboratory installation. LUIS VALDÉS. *Anales soc. españ. fís. quím.* 28, 932–43(1930).—In a Sierp process (*C. A.* 20, 1292) lab. app. Oviedo sewage was mixed with activated sludge in a 4:1 ratio and aerated. With a treating period of 6 sec. and at 10 l. of air per l. of sewage the effluent was quite clear and innocuous. The biochem. O_2 consumption in 5 days was 10 mg. per l. The drop in bacteria count was almost 90%. A Cl addn. of 2 mg. per l. sufficed for complete disinfection. The activated sludge contained 96.22% H_2O and the compn. of dry material was mineral 48.3, org. 51.7, N 4.78, H_3PO_4 3.02%. E. M. SYMMES

Is the use of carbon tetrachloride dangerous from a sanitary standpoint? K. B. LEHMANN. *Zentr. Gewerbehyg. Unfallverh.* 17, 123–33(1930); *Chimie & industrie* 24, 587–8(1930).—From a general discussion of the question L. concludes that, while the use of CCl_4 as a fire extinguisher is subject to certain limitations, its other industrial uses do not give rise to any great hazards. A. PAPINEAU-COUTURE

Preventing the harmful action of gases and waste waters containing phenols in the operation of gas producers (FELDHAHN) 21. The determination of lime in sugar factory juices by Blacher's method (BÖTTGER) 28. Chemical characteristics of cement pipe lining (CHAPPELL) 20.

Purification of water with use of activated carbon. MILLARD BRANDT (to Darco Corp.). U. S. 1,781,314, Nov. 11. The C is disposed in a previous bed of highly activated, firm, elec.-cond., O-absorbing particles in a container such as iron or steel and the container is electrically insulated (as by a rubber or bakelite lining) from the bed in such a way as to prevent the C from forming galvanic couples with oxidizable metals when the app. is in use, thus to make O adsorbed by the C available for reaction with impurities in the water. Various details of app. are described.

Distilling boiler-feed water. P. JOHANNSSON. Brit. 331,778, Oct. 7, 1929. Boiler-feed water is evapd. by use of waste or exhaust steam which has been superheated in a pipe system by waste heat from the boiler furnace. App. is described.

Filter bed suitable for sewage disposal plants. ANDREW LENDBRINK. U. S. 1,780,791, Nov. 4. Structural features.

Drying sewage sludge. WM. W. HARRITT (one-half to Leavitt L. Keene). U. S. 1,779,810, Oct. 28. Various details of app. and procedure are described.

Incinerator for garbage, etc. SOLOMON SPECTOR. U. S. 1,778,919, Oct. 21. Structural features.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

The influence of chemistry on the development of agriculture. F. HONCAMP. *Landw. Vers. Sta.* 110, 133–55(1930).—An address. J. R. H.

Significance of p_H and calcium content of soil and simple laboratory methods for

their determination. F. LEMKE. *Deut. Zuckerind.* 55, 559–62(1930).—L. discusses sand, clay and loam, classifies soils as to lime content, treats of the colloidal chem. aspects and cites references.

J. F. LEETE

Determination of hydrogen-ion concentration of soils by the quinhydrone method. I. Some factors influencing the p_H values. A. ITANO, S. ARAKAWA AND A. MATSUURA. *Bull. Agr. Chem. Soc. Japan* 5, 73–4(1929).—A definite amt. of air-dried soil is placed in a flask, and an equal wt. of neutral distd. H_2O is added (with humic or volcanic soil 1.5 wt.). The stoppered flask is shaken for 5 min. and the soln. is filtered through neutral paper. To 15 cc. of the filtrate is added 0.05 g. of quinhydrone, and the detn. is made as usual.

W. D. LANGLEY

Information regarding the composition of Montenegro soil types. E. BLANCK AND H. KEESE. *Chem. Erde* 4, 157–66(1929).—The comparison of a no. of soil analyses shows that the presence of a red color is not always indicative of a typical "red-soil." A high humus content may produce an unexpected chocolate or brownish color in a true red soil. The SiO_2, Al_2O_3, Fe_2O_3 and humus contents of soils obtained from various localities are compared with those of a typical red soil obtained from North Montenegro.

A. E. MIX

"Single value" soil properties. A study of the significance of certain soil constants. III. Note on the technic of the Keen-Raczkowski box experiment. J. R. H. COUTTS. *J. Agr. Sci.* 20, 407–13(1930); cf. *C. A.* 24, 189.—A description is given of a modified technic for the Keen-Raczkowski box expt., which is believed to be as accurate as, and more convenient than, the one employed earlier. The results obtained for pore space by the new method are very nearly the same as those with the older method. The old and new results obtained for water retention and swelling are not the same, but are related to one another by simple linear expressions, and correlations with other soil properties deduced from the old data are applicable also to the new. **IV. A further note on the technic of the "box" experiment.** B. A. KEEN. *Ibid* 414–6.—Preliminary exptl. results suggest that, like the wt. per unit vol., the swelling is a function of the degree of packing to which the material is subjected during the filling of the box. The fact that such inert material as pptd. silica can show a "swelling" when satd. with moisture raises the question as to how far imbibitional moisture is concerned in the vol. expansion of soil.

P. R. DAWSON

Soil valuation and examination. A. VON NOSTITZ. *Landw. Jahrb.* 71, 837–54 (1930).—A study of the effect of the use of hard water for sedimentation, of a no. of methods of dispersion and the fluctuations of temp. during the process studied. The relationships between the mech. compn. and water relationships are also considered.

GEORGE R. GREENBANK

The indirect determination of various soil characteristics by the hydrometer method. G. JOHN BOUYOUCOS. *Soil Science* 30, 267–72(1930); cf. *C. A.* 24, 5405.—Exptl. results are presented which tend to show that soil material which the hydrometer method dets. at the end of 15 min. and designates as total colloids of the soil has a close relationship to moisture equiv. and unfree H_2O of soils. Fourteen soils with colloidal contents varying from 10.4 to 65% are studied. The close relationship between the phys. characteristics of the soils studied makes possible their rapid detn. by the hydrometer method. The wilting coeff. appears also to be determinable indirectly by the hydrometer method.

M. S. ANDERSON

Determination of soil acidity. A. H. ERDENBRECHER. *Deut. Zuckerind.* 55, 541–8 (1930).—The following detns. were made on various soils: p_H of suspension water, p_H of K chlorate ext., Ca need according to Daikuhara, Ca need according to Kappen, acid consumed when 30 g. was suspended in 75 cc. 0.1 *N* H_2SO_4, detn. of *Azotobacter* content.

J. F. LEETE

A new method of estimating total carbonates in soils. AMAR NATH PURI. Imperial Inst. Agr. Research, Pusa, *Bull.* 206, 7 pp.(1930).—Stir 10 g. of soil with 100 cc. water in a conical flask and add 0.2–0.5 g. $CaSO_4$. Heat the mixt. to boiling, add 10 cc. of 0.1 *N* $AlCl_3$, shake and add 10 drops of a 1% alc. soln. of bromothymol blue. After vigorous shaking, the suspension is allowed to settle and the color of the supernatant liquid is noted. A yellow color indicates the presence of less than 1% of carbonates, while a green to blue color indicates more than 1%. Ten drops of a 1% alc. soln. of bromocresol green is then added and the color again noted. A golden yellow color indicates the absence of carbonates. If carbonates are present the contents of the flask are heated to boiling and titrated with 0.5 *N* H_2SO_4. The titration is complete when the supernatant liquid assumes a golden yellow color which persists on boiling the suspension for 2 min. and allowing to settle for 1–2 min. The method is sufficiently accurate for routine field and lab. detns.

K. D. JACOB

Determination of carbonates in soil. C. J. SCHOLLENBERGER. *Soil Science* **30**, 307–24(1930).—See *C. A.* **24**, 4347. M. S. ANDERSON

The determination of the readily available phosphorus of soils. EMIL TRUOG. *J. Am. Soc. Agron.* **22**, 874–82(1930).—It is suggested that the terms readily available and difficultly available be used in place of available and unavailable in referring to the P of the soil in relation to its availability to plants. The former probably exists as Ca phosphate and the latter as basic ferric phosphate. A rapid analytical method is proposed in which a 0.002 *N* soln. of H_2SO_4, buffered with $(NH_4)_2SO_4$ to a p_H of 3, is used in the proportion of 200 cc. of solvent to 1 of soil to ext. the readily available P of the soil. This high ratio probably lessens refixation of dissolved phosphates and more closely represents plant removal of P. The soil is agitated in contact with the solvent for 30 min. The P is then detd. directly in the filtered ext. by means of the Denigès colorimetric method. For general farming in Wisconsin there should be a min. of 75 lb./acre of readily available P for the heavier soils and 50 lb. for the lighter sandy soils. For garden and special crops this limit should be raised to 150 lb.
J. R. ADAMS

Some carbon-nitrogen relations in soils. WILBUR R. LEIGHTY AND EDMUND C. SHOREY. *Soil Science* **30**, 257–66(1930).—Analytical data obtained from 176 samples of soils from 63 locations in 12 states show the C:N ratio is highly variable. With few exceptions the ratio is highest in the surface soil and becomes less at lower levels. The values found vary between the extremes 3.5:1 and 35.1:1, relatively few values lying outside the limits 7:1 and 15:1. The C:N ratio gives some indication of the availability of org. matter as food for microörganisms. A ratio as high as 20:1 is indicative of a fair supply of decomposable org. matter. while a ratio of 10:1 or less indicates org. matter in a well-advanced stage of decompn. The data show the futility of attempting to calc. the org. matter by multiplying the total N by the factor 20 as has been proposed. M. S. ANDERSON

Studies on the carbon and nitrogen cycles in the soil. I. Introductory. H. J. PAGE. *J. Agr. Sci.* **20**, 455–9(1930).—A résumé of previous work on soil org. matter, particularly "humic matter," introducing a series of papers to follow. **II. The extraction of the organic matter of the soil with alkali.** C. W. B. ARNOLD AND H. J. PAGE. *Ibid* 460–77.—The alkali extn. of the org. matter from the soils of certain plots of the permanent expts. on Barnfield and Broadbalk at Rothamsted, receiving resp. org. manure, artificial fertilizers and no fertilizer treatment, was studied, together with colorimetric examn. of the exts. for the comparison of the content of humic matter. In spite of the different cultural and fertilizer treatments which the different plots had received, there was a marked similarity in the properties of the org. matter of these soils, with respect to its behavior on extn. with cold and hot dil. NaOH, and the color intensity of the org. matter in the exts. For both soils the org. C values for the soils themselves and for the exts. are very markedly higher in the plots to which manure was applied, both in the surface soil and subsoil. The excess of org. matter in the subsoil of manured plots is shown to be due to carrying down from the surface soil. The greater part of the C sol. in cold alkali is extd. in 4 hrs., only a slight increase occurring after 8–16 hrs. Extn. with hot alkali dissolves about 2 times as much C as cold and prolongation of the hot extn. beyond 3 hrs. produces no appreciable increase. The results appear to indicate that the org. matter of these soils is present in 3 forms, 1 readily sol. in cold alkali, another only slowly sol. in cold dil. alkali, but rapidly sol. in hot alkali and a 3rd which is insol. in hot dil. alkali. The org. C extd. from the surface soils is more deeply colored than that of the corresponding subsoils and is most deeply colored in the exts. from the surface soils receiving annually heavy applications of manure. The org. C in the exts. from the subsoils of the plots receiving no manure or artificial fertilizers is the least intensely colored of all. The wet combustion method used for the detn. of org. C in the soils and their exts. is described in detail in an appendix. **III. The formation of natural humic matter.** M. M. S. DU TOIT AND H. J. PAGE. *Ibid* 478–88.—Expts. are described in which the decompn. of various plant materials (wheat straw, clover hay, corn cobs and sawdust) and of purified prepns. of plant constituents (lignin, cellulose, xylan, xylose, starch, glucose and protein) was studied during rotting under neutral aerobic conditions in the presence of soil organisms, with relation to the formation of humic matter. Decompn. was followed analytically by estg. the surviving constituents of the plant materials. The degree of humification was estd. indirectly by comparing the tint of a freshly prepd. hot strong NaOH ext. of the material with that of a fresh NaOH soln. of an estd. humic acid prepn. The relative order of rates of rotting, as measured by loss of total org. matter, was, for the plant materials, in descending order: clover, straw, corn cobs, sawdust, *i. e.*, in order of protein content.

There was no direct relation to the relative content of furfuroids, sugars or cellulosic materials. The formation of humic matter bore a much more const. relation to the change in "lignin value" than it did to the changes in content of the other groups of plant constituents estd. P. R. DAWSON

Normal magnesium carbonate in comparison with "light" and "heavy" oxides and carbonates in the soil. W. H. MACINTIRE AND W. M. SHAW. *J. Am. Soc. Agron.* 22, 919–34(1930).—Comparative lysimeter expts. were run for 4 yrs. on 5 magnesic materials at 8-ton and 32-ton CaO-equiv. rates. The cryst. carbonate, $MgCO_3.3H_2O$, gave the greatest Mg outgo for both rates. At the 8-ton rate the greater losses from the other materials came from the "heavy" forms of oxide and carbonate and the losses from each oxide approximated those from the corresponding carbonate. At the 8-ton rate the Mg outgo from the carbonate was greater than that from the 32-ton "light" carbonate but this in turn was smaller than the outgo from the 32-ton rate of the "light" oxide. All magnesic materials depressed the outgo of CaO, the 32-ton addns. being approx. twice as effective as those of the 8-ton addns. The annual and total carbonate-bicarbonate leachings were parallel to the relationships shown for total Mg. All addns. caused a material repression in K_2O outgo, the heavier ones producing the greater repression. Sulfate outgo was uniformly enhanced by every material at both rates. Nitrification was accelerated by the 8-ton addns. of oxides and pptd. carbonates especially during the first yrs., the carbonates being more effective. At this rate the cryst. carbonate showed no accelerative effect while at the 32-ton rate it was repressive. The nitrate leachings from the "light" oxide and carbonate at the 32-ton rate were only about 70% of the outgo from the untreated soil. Plants grown after magnesic addns. showed smaller assimilation of Ca and K. J. R. ADAMS

Base-exchange property of organic matter in soils. W. T. MCGEORGE. Ariz. Agr. Expt. Sta., *Tech. Bull.* 30, 181–213(1930); cf. *C. A.* 23, 1980.—Twenty soils collected from various parts of the U. S. were examd. chemically, particularly as to org. constituents. The exchange capacity of highly org. soils is approx. a linear function of the % of C in the soil. There is no relation between the N or N-C ratio and the exchange capacity of highly org. soils. Base exchange in highly org. soils takes place in chemically equiv. proportions. With H_2O_2 as a reagent for destroying org. matter in soils, the loss in exchange capacity is approx. a linear function of the amt. of org. matter destroyed. This loss in exchange capacity is due to a destruction of the org. matter which functions in base-exchange reactions, *i. e.*, the active org. fraction is not simply rendered passive as happens when it is treated with solns. of Al salts. Digestion with H_2O_2 does not affect the replacement capacity of natural bentonites but destroys a definite part of the exchange capacity of synthetic zeolites. H_2O_2 is of value for the approx. detn. of the exchange capacity of the org. matter of soils by a "difference method." Lignin, lignocellulose and lignohemicellulose or related bodies function largely as the exchange compds. of soil org. matter. Lignin from corncobs, lignin from soil (prepd. by extn. with alc. NaOH), synthetic humus and lignohemicellulose (prepd. by extg. the soil with aq. NaOH) all showed a definite chemical equiv. exchange capacity. The tervalent Al ions of $Al_2(SO_4)_3$ or $AlCl_3$ cannot enter the org. exchange complex and replace the bivalent or univalent ions absorbed by the lignin or lignin-like bodies. There is a partial loss in replacement capacity of lignin-like bodies when they are leached with a soln. of $AlCl_3$, which loss is restored by treating the soil with a basic hydroxide or the soln. of a salt, such as an acetate, which will yield OH ions by hydrolysis. The investigation is being continued. C. R. FELLERS

Relationship between soil reaction, distribution of meadow plants type and yield of meadows. KLAPP. *Landw. Jahrb.* 71, 807–35(1930).—Optimium ranges are studied for soil reaction using a no. of meadow plants. For the majority of the plants the growth p_H range is of such width that the characterization of soil reaction by classification of the natural flora is indecisive. Highest hay yields are obtained at a p_H of 5.0–6.8, with a preponderance of the better feeding plants in the less acid areas. G. R. G.

Interrelation of nutrients and soil reaction on growth and inoculation of alfalfa. M. C. SEWELL AND P. L. GAINEY. *Soil Science* 30, 297–305(1930).—Alfalfa grown in pots contg. quartz sand and nutrient solns. indicate that soil reaction within the range of p_H 4.5 to 7.0 is a minor factor in affecting the growth of alfalfa, provided all the needed nutrients are supplied. Reaction may be an important factor in symbiotic fixation under conditions of limited nutrients. M. S. ANDERSON

Local variation of soil acidity in relation to soy bean inoculation. GEO. Z. DOOLAS. *Soil Science* 30, 273–87(1930).—Greenhouse pots of Putnam soil are prepd. by treating certain zones of the soil with reagents such as NaOH, H_2SO_4 and $Ca(OAc)_2$. Soy beans are grown in these pots and the influence of the treated zones is studied as affect-

ing root growth and nodulation. Soil areas as acid as p_H 3.8 to 4.6 depress nodulation and produce root injury. Areas of about p_H 5.6 show healthy root segments but sparse nodulation. Apparently healthy plants grow in soil-contg. areas as acid as p_H 4. However, if the entire root system is in soil as acid as this, abnormalities of growth are observed. Nodule organisms retain their viability in all soil media with degrees of acidity ranging from p_H 3.8 to 8.3. M. S. ANDERSON

Determination of the nutrient requirement of soils by field and pot experiments. E. A. MITSCHERLICH. *Landw. Jahrb.* 71, 445–67(1930).—A comparison is made of the contents and fertilizer requirements of a no. of soils by pot and field expts. The errors of the 2 methods are discussed. The first approximation to the effect law offers a satisfactory means of examn. GEORGE R. GREENBANK

The Atterberg consistency constants: factors affecting their values and a new concept of their significance. L. D. BAVER. *J. Am. Soc. Agron.* 22, 935–48(1930).—The Atterberg consts., (*a*) upper plastic limit, (*b*) lower plastic limit and (*c*) plasticity no. are affected by a no. of factors. Plasticity increases with the content of disk-shaped, colloidal particles in the soil. Soils contg. a high percentage of clay or colloids possess high plasticities. A low SiO_2-sesquioxide ratio of the colloidal material extd. from soils is assocd. with a low plasticity range on the moisture scale. The bivalent cations tend to increase the plasticity by raising both plastic limits; the K ion decreases plasticity and lowers both plastic limits and the Na ion lowers both plastic limits but increases plasticity. Org. matter causes plasticity to occur at high moisture contents. Max. adhesion occurs at a moisture content close to that of the upper plastic limit and is proportional to the plasticity no. The moisture range over which adhesion takes place and the moisture content at which max. adhesion occurs appears to be functions of the plasticity no. The range of max. compressibility is approx. the same as the plasticity range on the moisture scale and this max. compressibility is a logarithmic function of the plasticity no. The max. resistance offered by a soil to the passage of chisels is a logarithmic function of the plasticity no. A double logarithmic relationship exists between the plasticity no. and that moisture content at which the resistance of a soil to the passage of chisels begins to increase rapidly. From this and previous work the Atterberg consistency consts. appear to be a means of predicting the values of the dynamic properties of any plastic soil. J. R. ADAMS

Nitrogen and organic matter as related to soil productivity. W. L. POWERS AND R. D. LEWIS. *J. Am. Soc. Agron.* 22, 825–32(1930).—N and total C show marked increases after 16 yrs. from irrigation, crop rotation or manuring. This increase does not change the ratio between the N and C. The nitrate-supplying power of the soil appears to increase. Soil N and total C are related to crop yield, net profit/acre and H_2O cost of dry matter. J. R. ADAMS

The liming of soils in Cis-Ural and Trans-Ural regions. G. A. MALANDIN AND V. N. KOTOVA. *Trav. inst. recherches biol. univ. Perm* 3, 1–64(in English 64–71)(1930).—The territory of U. S. S. R. taken as a whole, as well as its part—Ural region, with regard to the soil cover, exhibits a great variety, and therefore the liming requires special attention. The soils are in need of lime to a degree which varies not only with various soil belts, but also within the same belt. The need of soils for lime was detd. by the degree of satn. of the soil with bases (according to the value V). This last is detd. by the formula $V = S/T\ 100$, as it is understood by Kappen, where S stands for the sum of adsorbed bases and T, for the max. adsorption of bases by soil at its treatment by hydrolytic alkali salt. The value S was detd. by the method of Kappen (the treatment of soil by 0.1 N HCl). The results obtained by the method of Kappen were compared with those obtained by the method of Gedroits (the treatment of soil by 1.0 N NH_4Cl). The data compared show a definite dependence of the exactness of the method of Kappen on the value S. The interdependence of the methods of Kappen and Gedroits as regards S allows one to establish corrections for S values, obtained by the method of Kappen. L. JACOVLEFF

The use of the antimony electrode in the control of cane juice defecation and for measuring the hydrogen-ion concentration of soils. N. GALVEZ. *Philippine Agr.* 19, 219–27(1930).—A method of cane juice clarification by intermittent liming is proposed which requires an Sb electrode and an indicator but no potentiometer recorder. The Sb electrode in connection with a satd. HgCl cell has the advantage over other electrodes for cane juice and soil detns. of cheapness, strength, ease of cleaning, quick response and accurate results when used continuously for at least 3.5 hrs. The av. probable error in p_H is about 0.08. In a series of tests the max. deviation from the true p_H was 0.3, which was obtained with a tarnished electrode that had been used in many different solns. without cleaning. A. L. MEHRING

Seasonal variation in the number of two species of Rhizobium in soil. J. K. WILSON. *Soil Science* 30, 289–96(1930).—Studies were made of the occurrence of *Rhizobium trifolii* and *R. leguminosarum* in plats at different times of the year. The nos. of *Rhizobium* organisms varied from as few as one in 50 g. of soil to as many as 100,000 per g. The nos. tended to be greatest in June and in Oct., and least in winter. M. S. ANDERSON

Decomposition of superphosphate in the soil and the effect of superphosphate on the reaction of the soil. NEUMANN. *Das Superphosphat* 6, 149–51(1930).—Water-sol. P_2O_5 is fixed in the soil principally by reaction with $CaCO_3$ to form $CaHPO_4$ and $Ca_3(PO_4)_2$, which are pptd. in an extremely fine state of division and can be utilized readily by plants. Superphosphate has no effect on the p_H of the soil. K. D. JACOB

A comparison of some effects of blast-furnace slag and of limestone on an acid soil. F. H. CRANE. *J. Am. Soc. Agron.* 22, 968–73(1930).—From greenhouse and lab. tests it was found that on the gross ton basis 100-mesh limestone was somewhat superior to 100-mesh slag in its effects on red clover growth and soil reaction. On the basis of $CaCO_3$ equiv., as detd. by titration with phenolphthalein as indicator, the 2 materials had nearly the same effectiveness. The $CaCO_3$ equiv. computed from the contents of total Ca and Mg was a less satisfactory measure of relative effectiveness as compared with clover yields and effects on soil reactions than the $CaCO_3$ equiv. obtained by titration. Four-ton applications of granulated slag gave results approx. equal to those from 1 ton of 100-mesh slag. J. R. ADAMS

The effect on plant growth of treating soils with copper-carrying pyrite. H. V. SMITH. *J. Am. Soc. Agron.* 22, 903–15(1930).—The addn. of waste pyrite carrying 1.26 to 1.63% Cu to 9 different soils causes an increase in the sulfate content of the soils, a lowering of the p_H value of the acid soils, and little or no change in the p_H of the alk. soils. The pyrite in the quantities used causes no Cu toxicity but in certain soils causes too high concns. of sol. salts for the best growth. Soils not originally well supplied with CaO become too acid for optimum plant growth. The S in both the Jerome and Nacozari pyrites is capable of fairly rapid oxidation to sulfate. Pyrite, carrying small quantities of Cu, can be applied to calcareous soils in fairly large amts. Acid soils should be treated with care, unless CaO also is used. J. R. ADAMS

Further studies on the fixation of atmospheric nitrogen by Azotobacter. KEN IWASAKI. *Biochem. Z.* 226, 32–46(1930).—In fluid cultures of *Azotobacter* cell division is stopped in low O_2 tensions and N_2 fixation is stimulated. The energy yield of oxidation is thereby increased for brief periods of time. In the presence of NH_4 salts the N_2 fixation ceases. Humin solns. increase the rate of growth and of respiration extraordinarily. These humin solns. are prepd. as follows: 100 g. of garden soil washed 3 times with HCl is shaken for 2 hrs. with 10% KOH and centrifuged. On acidifying this scln. with strong HCl a ppt. is formed which is centrifuged off, redissolved in KOH and pptd. again with *N* HCl. After repeating this twice the ppt. is suspended in 100 cc. H_2O to which enough KOH is added to dissolve the humin. The soln. is exactly neutralized with acid. Expts. show that humin has a great influence upon the assimilation of N but not on the N fixation, as it continues to produce its typical effect also in the presence of NH_4 salts. S. MORGULIS

Time of seeding small grains after tobacco and saving of nitrate. P. E. KARRAKER. *J. Am. Soc. Agron.* 22, 890–5(1930).—After the tobacco was cropped the plats were seeded to barley or wheat. The soil content of the nitrate accumulated during the growth of the tobacco was very effectively reduced by a large growth of early-seeded barley. Wheat seeded at or after the usual time was comparatively ineffective in this respect. J. R. ADAMS

Rate of loss of replaceable potassium by leaching. O. C. MAGISTAD. *Soil Science* 30, 243–56(1930).—Synthetic K zeolites when leached with distd. H_2O and the successive portions of leachate analyzed for K give data which can be expressed by an equation of the type $\log [A/(A-Y)] = KV^p$, where A is the absorptive capacity in milliequivs., K is a const., Y the loss in milliequivs., V the vol. in liters and p a factor which may vary for different zeolite materials. For artificial zeolites and noncalcareous soils the value for p is about 0.6 to 0.7. Calcareous soils give somewhat higher values for this factor, indicating a much slower rate of loss of K. It seems probable that for soils of a particular series a single set of consts. may hold fairly well, and that the use of an equation contg. these consts. would enable one to est. the rate of loss of K over periods of several years. M. S. ANDERSON

Progress in the fertilizer industry (phosphoric acid fertilizers) in the years 1925–1929. G. WICHERN. *Chem.-Ztg.* 54, No. 84, *Fortschrittsber.* 81–6(1930). E. H.

Fertilizer problems and analysis of soils in California. D. R. HOAGLAND. Calif.

Agr. Expt. Sta., *Circ.* **317**, 16 pp.(1930).—A general discussion of phys. and chem. properties of Calif. soils. C. R. FELLERS

World conditions as to chemical plant foods. C. C. CONCANNON. *J. Chem. Education* **7**, 2634–44(1930); cf. *C. A.* **24**, 4884. E. H.

Laboratory determination of the phosphoric acid and potash requirements of plants according to Neubauer's method. K. SOLON. *Deut. Zuckerind.* **55**, 557–8(1930).—The method is a combination of vegetation expts. and soil analysis. The optimum vegetation time is 14–15 days. J. F. LEETE

The importance of the water-soluble phosphoric acid in superphosphate. DIX. *Das Superphosphat* **6**, 139–42(1930).—The superiority of water-sol. phosphates as fertilizers for certain crops, such as the sugar beet, is largely due to the fact that the P_2O_5 can be used immediately by the young plants, thereby stimulating the root development and increasing the ability of the plant to use the less sol. forms of P_2O_5. K. D. J.

Use of superphosphate, ammonia-superphosphate and potash-ammonia-superphosphate mixtures on winter crops. GERLACH. *Das Superphosphat* **6**, 135–7(1930).—Superphosphate and mixts. contg. superphosphate can be used for the fertilization of winter crops grown on light sandy soils, without danger of loss of the H_2O-sol. P_2O_5 by leaching. Application of lime or marl does not decrease the fertilizer value of the P_2O_5. K. D. JACOB

Potash shale as a source of potassium for growing plants. HARRY C. HEATH. *Bot. Gaz.* **90**, 121–50(1930).—The use of untreated shale showed that considerable benefit is derived from it by plants grown in potash-deficient soils, especially peats. Shale, roasted with limestone or gypsum, may prove a valuable fertilizer in applications of 2 tons or more per acre. BENJAMIN HARROW

The Neubauer analysis and its relation to field experiments. KARL HESSE. *Landw. Vers. Sta.* **110**, 1–31(1930).—The fertilizer needs ascertained by the germinating plant method on single culture beds agree well with the results of field expts. The agreement is better with K_2O than with H_3PO_4. Inconsistent results found at many expt. stations are due to variation in the methods of carrying out the Neubauer analysis. The exposure to light of the germinating plants and the prepn. of the soil are important factors. A N fertilizer does not change the absorption of food materials by the germinating plants. JOHN R. HILL

Fertilizing rubber trees. FIRMAN E. BEAR. *Rubber Age* (N. Y.) **28**, 25–6(1930).—The merits of NH_4 phosphate are reviewed and discussed. C. C. DAVIS

Winter cover crop experiments at the Pee Dee Experiment Station. E. E. HALL, W. B. ALBERT AND S. J. WATSON. S. C. Agr. Expt. Sta., *Circ.* **42**, 14 pp.(1930).—Field expts. showed the following yields in lb. of N per acre: hairy vetch 92, Monantha and Hungarian vetch 83 and 62, Austrian winter peas 53, Austrian winter peas, limed and fertilized 142 and Canada field peas 19. The latter proved unsuitable as a winter cover crop because of winter killing. C. R. FELLERS

The fungicidal properties of certain spray-fluids. VII. W. GOODWIN, H. MARTIN AND E. S. SALMON. *J. Agr. Sci.* **20**, 489–97(1930); cf. *C. A.* **20**, 2223; **24**, 1697.—The fungicidal properties of solns. contg. S in polysulfide form were tested by application to the conidial stage of *Sphaerotheca humuli* growing upon young hop leaves. When 2 samples of Na_2S_x solns. prepd. in the lab. and 2 samples of com. prepns. were applied with 1% soft soap as the spreader, solns. contg. 0.5% polysulfide S were fungicidal. With 0.5% gelatin as the spreader, fungicidal strength did not begin to be attained until the concn. of polysulfide S reached 0.11%. Two lab. prepns. of K_2S_x behaved like the Na_2S_x solns., when applied at the same concn. of spreader and polysulfide S. Four samples of CaS_x solns., including 1 com. lime-sulfur, and 2 lab.-prepd. BaS_x solns., proved almost or quite fungicidal at concns. of 0.11% polysulfide S when applied with 0.5% gelatin. Solns. of CaS_x differing widely in the relative amts. of total and thiosulfate S behaved as fungicides in accordance with the polysulfide S content only. The fungicidal efficiency of the polysulfide S is independent of the base with which it is combined. The results confirm the view that the polysulfide S content is a measure of the fungicidal power of spray fluids of the polysulfide class. P. R. DAWSON

Effect of certain hydrocarbon oils on the transpiration rate of some deciduous fruit trees. VICTOR W. KELLEY. Univ. Ill. Agr. Expt. Sta., *Bull.* **353**, 581–600(1930); cf. *C. A.* **24**, 4350.—Satd. (highly refined, white) and unsatd. (colored) petroleum oils retarded the transpiration rates of apple, pear, peach, plum and sour cherry about 50–75% of the normal. When oil emulsions were sprayed on the upper surfaces of leaves transpiration was not affected; when applied to the lower surfaces a marked retardation resulted. Spraying both surfaces had no more effect than spraying the lower surfaces. The effect was greater on old than on young leaves, and increased with increase of oil

concn. in the spray. The lowest concn. used (0.5% oil) caused a definite decrease in rate. The stomata of leaves which have been sprayed on the under surface with oil emulsions do not open as widely as those of unsprayed leaves, possibly because of a reduction of sol. carbohydrate in the sprayed foliage which lowers the turgidity of the guard cells. No const. difference in effect on transpiration between satd. and unsatd. oils was noticed; the effect is probably phys. rather than chem. The influence on transpiration rate is soon apparent and measurable 30 min. after application of the oil spray and continues a long time. *Conclusion:* Oil sprays should be used with caution. Highly refined (white) oils may not guarantee against injury. The under sides of leaves should not be sprayed unless it is essential for the control of insects. Oil sprays should not be applied when the humidity is very high. C. H. RICHARDSON

Seed-grain disinfection experiments with chemicals during the years 1925 to 1929 and hot water disinfection of barley. I. JØRSTAD AND A. E. TRAAEN. *Meldinger Norges Landbruks.* **1930,** 1–56; *Rev. Applied Mycol.* **9,** 638–9.—A full account is given of the use of a large no. of both liquid and dry chem. prepns. against wheat bunt, covered smut of barley, loose and covered smut of oats and barley stripe in the disinfection of seed grain in the official Norwegian expts. O. E. SHEPPARD

Investigation on the toxic action of copper-containing compounds on bees. BORCHERT. *Berl. tierärtz. Wochschr.* **1930,** 84; *Rev. Applied Mycol.* **9,** 664–5.—Cu-contg. plant protectives (Cu sulfate and basic Cu carbonate) plus sugar and honey water were fed to bees in varying concns. and the concn. at which 25% were killed was detd. The toxic dose of 5 Cu-contg. fungicides was 8.8 millionth g. Since these disinfectants are naturally bitter and not as a rule artificially sweetened, the danger to bees from their use may be considered negligible. O. E. SHEPPARD

Killing field weeds with chlorates. C. J. WILLARD. Ohio Agr. Expt. Sta., *Bimonthly Bull.* **146,** 158–68(1930).—From 1 to 4 lb. per sq. rod applied as a water spray was very effective in destroying such weeds as quack grass (*Agropyron repens*), Canada thistle (*Cirsium arvense*) and poison ivy (*Rhus toxicodendron*). Usually from 1 to 3 sprayings are required for complete eradication. The soil is only temporarily sterilized, and the following crops are usually uninjured. Because of the fire hazard, $NaClO_3$ must be handled very carefully. C. R. FELLERS

Moringa aptera seed from Egypt [as fertilizer] (ANON.) **27.** Determination of K in very dilute solutions and in soil extracts (WRANGELL.) **7.** Quantitative spectral analysis [of K in soils] by means of x-rays (v. HEVESY) **3.** Dhupa kernels from India (ANON.) **27.** Chinese tung oil seeds [as fertilizers] (ANON.) **26.** The utilization of the [world] over-production of molasses [as fertilizer] (CLAASSEN) **28.** Treating sulfate minerals such as alunite, etc. (Brit. pat. 331,552) **18.** Sulfonylchlorides [as insecticides] (Brit. pat. 331,596) **25.** HCN and its use in fumigation (U. S. pat. 1,780,196) **18.** Stable diazo compounds (Brit. pat. 332,227) **25.** Use of dried seaweed as a preservative packing material (Brit. pat. 331,546) **12.**

Fertilizer and sodium bicarbonate. SOC. CHIMIQUE DE LA GRANDE PAROISSE (Azote et produits chimiques). Brit. 331,451, Nov. 20, 1928. $NaNO_3$ and KCl are caused to react to form KNO_3 and NaCl and this mixt. is treated with CO_2, NH_3 and water to form $NaHCO_3$ and NH_4Cl (and, if untransformed $NaNO_3$ is present, also forming NH_4NO_3) and the $NaHCO_3$ is separately recovered from the other materials which form a mixed fertilizer. Various details and modifications of procedure are described.

"Double superphosphate." WM. B. KING (to Armour Fertilizer Works). U. S. 1,780,620, Nov. 4. A slurry of ground phosphate rock and dil. H_3PO_4 soln. is concd. by heat to a thick liquid only, the liquid is allowed to set to a solid condition after termination of the heating action, and the solid material is dried.

Apparatus and procedure for sterilizing, disintegrating and drying waste fish material, etc. W. H. HASLAM. Brit. 332,241, April 16, 1929.

_____ coating materials such as insecticides. JAMES R. NEILSON (one-half to Earl M. Morley). U. S. 1,781,188, Nov. 11. A plastic mixt. of a material such as Pb arsenate together with gum arabic and brown sugar and water is molded into forms such as thin blocks which provide a substantially constant surface area as they dissolve away, and the molded material is subjected to the action of water under pressure.

Disinfectant for control of seed and plant diseases. MAX ENGELMANN (to E. I. duPont de Nemours & Co.). U. S. 1,780,008, Oct. 28. A mixt. is used comprising a thiosulfate such as that of Na, together with ethyl mercuric chloride or other suitable

Hg compd. of the general formula R-Hg-X, in which R is an alkyl group and X is an acid group. Cf. *C. A.* **24**, 5928.

Organic mercury compounds suitable for use as seed disinfectants. E. I. DUPONT DE NEMOURS & Co. Brit. 331,494, Jan. 21, 1929. A Hg salt such as $HgCl_2$ or $Hg(OAc)_2$ is caused to react with Et_4Pb, Ph_4Sn, Et_3PbCl, tetrabenzyl-Sn or similar alkyl, aryl or aralkyl deriv. of a quadrivalent metal above Hg in the electrochem. series (or with the reaction products of a Na-Pb alloy and alkyl sulfate or the like). Several examples are given. Cf. *C. A.* **24**, 5928.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Production, application and detection of methanol and isopropyl alcohol. K. BODENDORF. *Apoth. Ztg.* **45**, 1141–4(1930).—An address dealing with both the earlier and present methods of manuf., their various uses and methods of detection.

W. O. E.

The influence of the p_H value of the medium on alcoholic fermentation. I. L. CASALE. *Ann. chim. applicata* **20**, 336–53(1930).—The max. velocity of fermentation occurs when the p_H value of the medium is between 3.3 and 4.0; the max. yield of EtOH is obtained with p_H 2.8 and 5. In all cases the sugars are completely utilized, except at p_H 2.8 initial value and 2.6 final value. In this case the enzymes multiplied as usual, but activity of the zymase is arrested. The yield of lactic acid is higher with high original p_H values, while the formation of volatile acids is fairly const. **II. Influence of the reaction products of fermentation on the velocity of multiplication of yeast cells.** *Ibid* 353–7.—Because the reaction products in fermentation are acids, they retard fermentation, except in cases where the medium is originally alk. **III. Alcoholic fermentation in liquids with high hydrogen-ion concentration.** *Ibid* 357–61.—At concn. of p_H below 2.5 cell multiplication and enzyme action are arrested, while the activity of other enzymes, as those of lactic and formic acids, as well as AcH, persists. The presence of AcH in strongly acid media is not, therefore, an intermediate product in alc. fermentation, but is, rather, the product of another enzyme; possibly it is derived from lactic acid, as suggested by Schade. A. W. CONTIERI

Selective fermentation. I. Alcoholic fermentation of glucose, fructose and mannose mixtures. HARRY SOBOTKA AND MIRIAM REINER. *Biochem. J.* **24**, 926–31 (1930).—All types of yeast preferred glucose to fructose at a rate of 2:1 or higher.

BENJAMIN HARROW

The economic significance of lowering the cost of yeast and alcohol production from molasses. H. CLAASSEN. *Deut. Zuckerind.* **55**, 935(1930).—A discussion.

J. F. LEETE

Electricity in fermentation and storage vats. A. HALLERMANN. *Wochschr. Brau.* **47**, 279–82(1930).—H. describes his experience on Al vats embedded in reënforced concrete, with a layer of pitch and wrapped in jute. Iron-coated and vat-varnished attemperating coils were used; the outlet pipes were made of bronze and were protected from the Al by insulation. Although the concrete remained entirely dry and the iron embedded therein was not rusted there are possibilities for galvanic currents to pass the fermenting vat. Measurements showed that there is no complete insulation between vat walls and attemperating coils and 8 milliamps. were recorded on the ammeter. According to Faraday's law but 100 g. Al would be used up per annum in a unit of 5 vats, compared with the total weight of 2200 kg. of the entire outfit. It has to be considered, however, that the 8 milliamps. recorded were detected under most favorable connections to the current since all connections were carefully cleaned when the measurements were made. The embedding, however, could be improved. S. JÓZSA

Electricity in vessels (in brewing). S. JAKOB. *Wochschr. Brau.* **47**, 285–9(1930).—Galvanic corrosion in metal vats is discussed. Data are given showing the amts. of Fe, Al and Cu used up by currents of different strengths (0, 1, 1, 0, 10, 20 and 100 milliamps.). Measurements on a 140 hl. vat with a surface of 26 sq. m. equipped with a Cu swimmer of 1.6 sq. m. surface showed about 2 milliamps. which would use up 48 g. Al per annum. Elec. currents can also be observed in other brewing vessels as, *e. g.*, in mash tubs, filter tubs and straining vats. The conditions for corrosion in a straining vat are very favorable, the iron floor being about 10 mm. below the bronze draining surface. The lifetime of the iron floor is much shorter than that of the draining floor. J. describes the Toat oxidimeter, advocating its application to corrosion studies. This instrument is also useful for the detn. of insulating efficiency of different types of pitch. S. J.

Influence of carbon dioxide on fermentation by yeast. HOFMANN. *Wochschr. Brau.* **47**, 228–30(1930).—There has been much uncertainty as to whether alc. fermentation is brought to a standstill by high concns. of CO_2. A brief review of the earlier works on this subject is given (Prandtl, Foth, Hansen, Stockhausen and Windisch; Kolkowitz, Lieske and Hofmann). The main difficulty in such expts. is the compulsory use of very high pressure, and under such conditions some other factors also may come into play. Parallel expts. with H showed that fermentation ceased at 150 atm. pressure. H. concludes that there is no doubt that CO_2 dissolved in high concns. inhibits fermentation. S. JÓZSA

Modification of the degree of fermentation and of the respiration quotient of yeast. O. MEYERHOF AND KEN IWASAKI. *Biochem. Z.* **226**, 16–31(1930).—The influence of the *z*-factor discovered by Euler in yeast ext. has been studied on the fermentation of live yeast in N_2 or O_2. Under conditions of opt. concn. the anaerobic fermentation of *Saccharomyces ludwigii* is 100–200% greater than in a sugar-phosphate soln., and 100% greater for pressed yeast. The effect of the yeast ext. can be detected even in a diln. of 1:1000. At the same time the oxidation quotient is greatly increased although the respiration is unchanged. The effect increases with a rise in temp. and is scarcely noticeable at 10°. The increase in fermentation activity is independent of the sugar concn. The *z*-factor is present in the live yeast and is given off to the medium, especially in the presence of sugar and O_2. For this reason the anaerobic fermentation is considerably increased in a yeast suspension shaken for several hrs. with an oxygenated sugar-phosphate soln. from which the yeast suspension has been centrifuged off. The expts. also indicate that this *z*-factor is continuously produced and given off to the medium by the yeast. S. MORGULIS

Germ-removing filter applied in brewing. F. HARDER. *Wochschr. Brau.* **47**, 305–9(1930).—The Seitz E. K. filter has been successfully used in the wine industry for several years and its application in the brewing industry is emphasized. The app. tested had 80 filter layers, each 30 cm. (1 ft.) in diam. The handling is very simple and easy. The pressure required varies according to the condition of the beer and ranges from 1.5 to 3.0 atm. A detailed filtering expt. on pale beer is described. The costs per hectolitre (about 25 gallons) are 0.5 R.M. (12.5 cents). The stability of beers was found to be greatly increased; even spoiled beers were improved remarkably. A beer filtered through this E. K. filter is, however, very sensitive to further infection probably because of certain protective substances removed by filtration. S. JÓZSA

Technology of malting. IV. Cold and warm flooring method. E. JALOWETZ. *Brau- und Malzindustrie* **1**, 1–5(1930).—The influence of temp. on the decompn. of carbohydrates and protein during malting has been studied. The malting of the same Hanna barley was carried on with proper operations in 2 different ways, (1) at cold (10–13°) and (2) warm (20–22°) flooring temp. The 2 resulting malts were mashed in the usual way in the lab. and the worts were investigated for ext., dextrin, sol. albumins, formol- and ammoniacal N, acidity and increase in color. The malt which was produced in the cold way was richer in all these constituents than the "warm" one. The same detns. were made on the germs and their compn. was found to be parallel with that of the corresponding malt. Thus decompn. of protein and carbohydrates progressed within certain limits with lower temp. More protein was made sol. in the "cold" malt and passed over into the germs. Accordingly the germs of the cold malt showed a higher content of total and sol. N. Conclusion: It seems partly possible by proper adjustment of temp. during malting to regulate the albumin content of malts being produced from barleys rich in protein. Tables showing detailed analysis are included. V. **Influence of the composition of steep water.** *Ibid* **2**, 25–7.—Steeping expts. were carried out on the same barley with 4 different waters, 3 of which had been artificially prepd.: (1) well water, (2) lime and gypsum water, (3) lime water and (4) gypsum water. Ext., acidity, sol. albumins, formol- and ammoniacal N and increase in color were detd. in the worts and in the germs. The results showed that the mineral compn. of steep water had no effect on the constituents and character of the malt. The only exception was a remarkable increase in color after boiling with hops in the malts treated with alk. water. Tables with analysis are given. S. LAUFER

The p_H value of wines: conservation and chalking. VALENTINO MORANI AND LUIGI MARIMPIETRI. *Ann. chim. applicata* **20**, 313–35(1930).—In a previous paper (*C. A.* **24**, 2541) it was shown that the curve of neutralization of wine acids, measured potentiometrically, shows a sharp inflection when mineral acids had been added. It is now shown that even when chalk is added to neutralize added mineral acids, that this addn. can be detd. by the variation in the p_H value, which is always low compared to that of unadulterated wines. The potentiometric method is thus useful here. A no. of

tables of p_H values corresponding to measured electromotive forces are included.
A. W. C.

Volatility of magnesium acetate in wines. W. E. PATTERSON AND J. W. BAWTENHEIMER. *Can. Chem. Met.* **14**, 287–8(1930).—De-acetization of wines of good quality but which are rendered unpalatable by acetic condition is studied. Sufficient $MgCO_3$ must be added completely to neutralize all acid, fixed and volatile. Fifty % excess of the $MgCO_3$ equiv. is required to reduce the total acidity to zero. A study of 3 types of wines with wide differences in acid content shows that Mg acetate, in the absence of a hydrolyzing agent, such as tartaric acid, is volatile to a relatively small degree.
W. H. BOYNTON

The protein-tannin compound (in beer). B. D. HARTONG. *Wochschr. Brau.* **47**, 295–7(1930); cf. *C. A.* **24**, 2233.—H. concludes that the beer contains a certain colloid composed of protein, tannin and silicic acid, which further contains adsorbed ions. These colloids will be pptd. if the colloid stability is disturbed for any reason. The ppt. has the same compn. as the colloid compd. This coagulated compd. is a combination of protein and tannin. H. found that the ratio protein : tannin is always the same in the coagulated ppt. for the same type of beer. The pptd. matter was analyzed; a high ash content was found; and the amt. of N obtained was much less than could be expected for pure protein.
S. JÓZSA

Seed grain disinfection experiments with chemicals during the years 1925 to 1929 and hot water disinfection of barley (JØRSTAD, TRAAEN) **15.**

Denaturing alcohol with butyl chloride. WM. J. BANNISTER (to Commercial Solvents Corp.). U. S. 1,779,687, Oct. 28. About 1–5% of the BuCl is added. Brucine sulfate also may be added.

Citric acid by fermentation. FRANZ KANHÄUSER (to Montan- und Industrialwerke vorm. Joh. Dav. Starck). U. S. 1,779,001, Oct. 21. For effecting the fermentation of carbohydrate material such as sucrose or other sugar by mold fungi such as *Aspergillus niger*, the mold stock is cultivated in alternate stages including cultivation in a solid culture medium such as gelatin or agar agar, cultivation in liquid culture media under conditions corresponding to industrial fermentation, and cultivation on vegetable culture media contg. org. acids and vitamins followed by use of the mold stock for the industrial fermentation.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

The lavender essence industry in Italy. PAOLO ROVESTI. *Industria chimica* **5**, 1116–25(1930).—An outline of the present status of this industry is given. A. W. C.

Simple preparation of anesthetic ether from commercial ether. L. M. V. D. BERG. *Pharm. Weekblad* **67**, 1029–33(1930).—Com. ether is shaken 1 min. with an equal vol. of tap water, the H_2O drawn off and the operation twice repeated. The Et_2O is then dried 24 hrs. over $CaCl_2$ and distd. over an elec. lamp. The yield is 52% of a product which meets all the Pharm. requirements of anesthetic ether. A. W. DOX

Copper contamination of some iron preparations. F. GRENDEL. *Pharm. Weekblad* **67**, 1050–2(1930).—Detns. of Cu in 16 of the Fe prepns. listed in the Dutch Pharm. gave values ranging from 0.01 to 0.80 mg. per 10 g., with the notable exception of Ferrum pulveratum, where the Cu content was 6.0 to 7.5 mg. per 10 g. The bearing of these traces of Cu on the treatment of anemia is discussed. A. W. DOX

The efficacy of commercial preparations of anterior lobe of hypophysis. S. JANSSEN, A. LOESER AND P. NOETHER. *Arch. exptl. Path. Pharmakol.* **151**, 175–87(1930).—The criteria used were the ability of the exts. to cause follicular growth, ripening and formation of corpora lutea in infantile female rats, and to inhibit ovulation in the hen. All the com. prepn. tried (11) were completely ineffective; moreover, all depressed the blood pressure of the cat, an effect not observed in fresh active aq. exts. H. EAGLE

Powdered anterior lobe of hypophysis and the ovary. II. Quantitative titration of the efficacy. S. JANSSEN AND A. LOESER. *Arch. exptl. Path. Pharmakol.* **151**, 188–96 (1930).—The criterion recommended in testing the efficacy of an ext. is the proportion of animals which give pos. results with a measured quantity. So measured, anterior lobe of cattle, dried in acetone and kept over P_2O_5, had practically the same efficacy as fresh glands.
H. EAGLE

Experiments in the physiological titration of belladonna extract and other drugs with atropine-like effect. L. JENDRASSIK AND G. WILL. *Arch. exptl. Path. Pharmakol.* 153, 94–108(1930).—The atropine content of any prepn. can be detd. by its effect upon the amplitude of contraction of surviving rabbit intestine kept in a fluid with const. pilocarpine concn. So titrated, *l*-hyoscyamine is twice as strong as atropine; homatropine is only $^1/_{10}$ as strong. On testing new exts., the physiol. method gives results closely approximating those obtained by chem. analysis. In old atropine or hyoscyamine exts. the physiologically demonstrable substances are only a fraction of the total alkaloid content. H. EAGLE

Chemical characterization of drugs. IX. Sinistrin and mucilage in bulbus scillae. L. ROSENTHALER AND R. KOHLI. *Apoth. Ztg.* 45, 1097–9(1930); cf. *C. A.* 24, 465.—An exptl. study showing that the sinistrin obtained exists in 2 forms; it is not split by enzymes nor pptd. by tannin, HBr or silicotungstic acid; it does not possess the characteristics of a mucilage. The latter substance does not occur in the parenchyma but occurs rather in the raphidiferous cells. For localization studies, sections of scilla are boiled several times in dil. alc., the solvent is evapd., $Sr(OH)_2$ added to the exhausted section and the section immediately observed under the cover glass, whereupon sinistrin-Sr will appear in the parenchyma cells. W. O. E.

Acidimetric estimation of theobromine in diuretin, calcium diuretin and other theobromine preparations. HEINRICH BOIE. *Pharm. Ztg.* 75, 968–9(1930).—Dissolve 0.5 g. of the sample in 100 cc. hot H_2O, and add 15 cc. 0.1 *N* H_2SO_4. Expel the CO_2 from the acid soln. by boiling, cool to 40°, add 1.5 cc. phenol red soln. as indicator, render distinctly acid with 2 to 3 cc. 0.1 *N* NaOH soln., then titrate to an acid reaction with 0.1 *N* H_2SO_4. To the resulting soln. add 20 cc. (an excess) 0.1 *N* $AgNO_3$ soln. and titrate the liberated HNO_3 with 0.1 *N* NaOH to a distinctly deep violet-red tone. From the no. of cc. of 0.1 *N* NaOH thereby consumed, calc. the amt. of theobromine Ag (or theobromine) formed. Only a few min. is required for the above operation on account of its simplicity and dependability. Similarly, other derivs. of theobromine can be detd. The results obtained in the examn. of some 23 different samples are reported. W. O. E.

Examination of surgical dressings for presence of germs. C. A. ROJAHN AND WALTER SCHILL. *Apoth. Ztg.* 45, 1183–6(1930).—Results obtained in this investigation indicate that the com. brands of surgical dressings examd. are practically sterile, this condition having been effected by an appropriate combination of antiseptic and aseptic sterilization. W. O. E.

Majoles. E. UBRIG. *Apoth. Ztg.* 45, 1186–9(1930).—This contribution to the standardization of vials (Majole being the term applied by manufacturers to the standardized type of vial) is an attempt to show the ideal type and character of the standard vial, and to describe (by illustration) the various operations of manuf., filling, sealing and labeling. W. O. E.

The problems of the pharmacopeia for the physician, apothecary and drug industry. E. STARKENSTEIN. *Pharm. Post* 63, 445–8, 453–6, 465–70, 477–83, 489–96(1930).—An address. W. O. E.

Adulteration of cortex granati. GUNDIS ROTTER. *Pharm. Monatshefte* 11, 173 (1930).—A recently observed adulteration of this drug is reported which involves manipulation of the genuine product with brick powder or red clay. W. O. E.

Examination of the active constituents of Asarum europeum from the chemical medico-legal standpoint. JULIUS ORIENT. *Pharm. Monatshefte* 11, 174–6(1930).—*Asarum* root contains 2 principal constituents, an aromatic deriv. asaron and asaron oil (several fractions) of undetd. constitution. Animal expts. show asaron does not possess a local action when applied externally, but exercises a narcotic effect when administered internally *per os* or subcutaneously, being non-toxic and eliminated from the body. The oil, however, is toxic, producing hyperemia in all the organs, inflammation of the kidneys and uterus, and finally death, a fact explaining its use to some extent as a popular abortifacient. In the event of possible intoxication from *Asarum* root, a histological and microchem. examn. should be made of any residual plant particles. Asaron oil can be detected in urine and stomach contents by chem. tests. W. O. E.

Reactions of morphine and other alkaloids of opium. LAD. EKKERT. *Pharm. Zentralhalle* 71, 550–1(1930); cf. *C. A.* 23, 2532.—The reagent employed is a soln. of 1 g. *p*-dimethylaminobenzaldehyde in 1 cc. concd. H_2SO_4; on treating 0.1 mg. morphine with 1 drop of this reagent, a blood-red color immediately develops. Codeine, ethylmorphine, heroine and cryptopine behave similarly. The artificial products eukodal, laudanon, narkofin and parakodin develop reddish brown tones at first, changing on diln. with H_2O to more decided red colors. W. O. E.

Reactions of sulfonal and trional. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 550 (1930).—On treating 0.01 to 0.02 g. of the sample (sulfonal) with a like amt. of resorcinol in 0.3 cc. concd. H_2SO_4 in a test tube, heating very carefully over a small flame, to the appearance of rose-red, red-brown, green, then dilg. the cooled soln. with 5 cc. H_2O, and rendering ammoniacal, a rose-red color will persist. Similar treatment of trional leads to a brownish yellow to reddish brown color. W. O. E.

Roumanian peppermint oil and the rise of this industry in Roumania. ELEMER KOPP. *Pharm. Zentralhalle* **71**, 577–82(1930).—A comprehensive study of the oils obtained over yearly periods beginning with 1925, the results thereby obtained being arranged for comparative purposes in tabular form. W. O. E.

Preparation of sulfureted balsam-like masses from wood tar. E. PALLAS. *Pharm. Zentralhalle* **71**, 609–11(1930); cf. *C. A.* **24**, 4382.—One of the 2 types of tar obtained in the destructive distn. of wood, notably that termed "Essigteer," yields on repeated extn. with hot H_2O, and subsequent treatment with SO_2 and $Ca(OH)_2$, with final evapn. to the desired sirupy consistency, a clear product possessing high antiseptic activity toward the lower organisms, notably bacteria. W. O. E.

Testing of ampoule glass for alkalinity. CONRAD STICH. *Pharm. Ztg.* **75**, 482 (1930).—Criticizing the official Ger. method, S. suggests a test involving treatment of the inner surface of the ampoules (80) with 0.01 *N* HCl and 1 drop of methyl red for 15 min. at 100° in a water bath. The liquid is then withdrawn and observed in a 100-cc. cylinder for retention of the red color. W. O. E.

New Brazilian Pharmacopeia. KARL MEYER. *Pharm. Ztg.* **75**, 941–7(1930).—A crit. review of this new revision, more particularly of the general and special divisions. W. O. E.

Keeping qualities of quinine. R. DIETZEL AND K. SÖLLNER. *Pharm. Ztg.* **75**, 955–7(1930).—The keeping qualities of quinine-HCl in aq. soln. have been studied when exposed for varying periods to diffused daylight, as also to that of short wave length when delivered by the quartz lamp. Short-time exposure effects little change; longer time (up to 60 days) produces more profound changes in the compn. as shown in the plotted curves. Continual exposure leads to the formation of a new, as yet undetd. *substance*, possibly a dimeric condensation product involving the union of 2 mols. of quinine through the ethylene bridge of the quinuclidine ring, in some way similar to the transition of cinnamic to truxillic acid. The new substance has a lower rotatory power than quinine. W. O. E.

Economic drug testing. II. Determinations. L. ROSENTHALER. *Pharm. Ztg.* **75**, 1087–8(1930); cf. *C. A.* **24**, 686.—The following procedure is suggested for estg. the alkaloids in powd. cinchona bark: Cover 0.2 g. of the sample in a 10-g. medicine bottle with 0.1 g. HCl and 1 g. H_2O, immerse in a boiling water bath, then shake the closed container 5 min. vigorously. When cold add 1.5 g. $CHCl_3$, again shake vigorously, add 0.5 g. NaOH soln., shake again 1 min. Now add 2.5 g. Et_2O and 0.2 g. tragacanth, shaking the mixt. 1 min. Pour 2.5 g. of the clear liquid into a 100 cc. flask, add 1 cc. 0.1 *N* HCl and 50 cc. of H_2O, then heat on the water bath to expel the Et_2O and $CHCl_3$. After cooling, fill to the mark with H_2O, withdraw 12.5 cc. of the liquid to a measuring cylinder, add 1 cc. Mayer's reagent, dil. to 20 cc. with shaking, pour into a test tube and compare with a test tube of like diam. contg. 1 mg. quinine treated as above. When the mixt. in the 1st test tube shows equal turbidity with the 2nd, then the sample of cinchona taken contains at least 6.5% of alkaloid. W. O. E.

Estimation of minute quantities of tannins. I. G. OBERHARD AND A. V. SCHALBEROWA. *Pharm. Ztg.* **75**, 970–1(1930).—The method employed involves the use of strips of specially prepd. gelatin-$FeCl_3$ paper, subsequently treated with varying amts. of a 0.1% soln. of gallic acid in a series of test tubes. A filtered soln. of the unknown is distributed in varying dilns. (1:5, 1:10, etc.) among 3 to 5 test tubes, into each of which is introduced a strip of the prepd. paper and allowed to stand for a period of 60 min.; preferably at the same time the control series is prepd. Comparison with the latter permits an estimate of the amt. of tannin in the sample under examn. W. O. E.

Pharmacological detection of poisons. P. PULEWKA. *Süddeutsche Apoth.-Ztg.* **70**, 517–8(1930).—The application of certain pharmacol. tests for poisons is advocated in pharmaceutical practice, notably in the detection of nicotine, veratrine, strychnine, morphine, atropine, etc., to which end suitable provision should be made in pharmaceutical curricula. W. O. E.

Examination of ergot. FISCHER AND HORKHEIMER. *Süddeutsche Apoth.-Ztg.* **70**, 518–9(1930).—The advisability of treating the drug with petr. ether for removal of the fats is emphasized as a preliminary to an estn. of the alkaloids. The authors' experience

in the examn. of certain samples of ergot is described, notably in cases of substitution. Of 15 different samples of the crude drug, 9 failed to conform with requirements of the DAB 6. W. O. E.

A chemical study of psyllium seed. JOSEPH S. HEPBURN AND THOMAS L. LAUGHLIN, JR. *Am. J. Pharm.* **102**, 565-8(1930).—Psyllium seed has the following percentage compn.: total solids 91.50, moisture 8.50, crude fat 6.40, total ash 3.16, insol. ash 2.95, sol. ash 0.21, crude protein 17.83, crude fiber 11.50, N-free extractives 52.61, pentosans 9.85 and galactans 0.31. Alky. of sol. ash, 6.48 cc. of *N* acid required to neutralize the ash yielded by 100 g. of total solids; alky. of insol. ash, 41.72. Reducing sugars were not present. The crude gum was tasteless and odorless and contained 16.45% pentosan and 0.02% galactan. The gum was boiled with 50 times its wt. of H_2O, filtered through linen and 5 cc. of the soln. used in each of the following tests: 1 cc. 25% $FeCl_3$ soln. produced a marked darkening in color which disappeared on addn. of 15 cc. of 50% alc.; no ppt. was formed; 1 cc. U. S. P. Pb subacetate soln. produced a curdy ppt.; 2 cc. 10% $CuSO_4$ soln. produced a transient mahogany color; further addn. of an excess of 5 cc. 5% soln. of NaOH produced a voluminous flocculent bluish green ppt. which did not dissolve on boiling; 2 cc. of 5% KOH soln. followed by shaking produced a yellow froth; several drops of Lugol's I soln. produced no change save the color due to the presence of I (starch and erythrodextrins therefore were absent); 10 cc. of 95% alc. produced only a faint turbidity on mixing; in a few moments a marked flocculent ppt. appeared, at first filling the whole tube and gradually depositing on the bottom; 5 cc. of 36% HCl and boiling darkened the soln. and imparted to it a faint purple tinge; 5 cc. of concd. H_2SO_4 and boiling produced only a caramel odor; the odor of org. acids was not noticed; 5 cc. of 85% H_3PO_4 produced, on boiling a darkening of color, and the evolution of a fragrant odor; the odor of org. acids did not appear; Fehling soln. was not reduced; 5 cc. of 2% borax soln. produced no change; repetition of this test with 5 cc. of 4% soln. of borax gave the same result; 5 cc. of 10% Pb acetate soln. produced a slimy, flocculent, voluminous, pale yellowish green ppt. A bibliography is appended. W. G. GAESSLER

The examination of cresyl-bearing extracts of ginger. PETER VALAER. *Am. J. Pharm.* **102**, 571–4(1930).—Examn. of adulterated fluidexts. of ginger which acted specifically on the lower motor neurons of human beings and caused paralysis showed the presence of a cresol compd. found to be in the ester form as tri-*o*-tolyl phosphate to the extent of about 2% by vol. When this adulterated ginger is evapd. at low temp. to a small vol. by a downward current of air there are formed 2 distinct layers: one a yellow upper layer in which was found some alc., water and diethylene glycol; the lower black layer contained principally tri-*o*-tolyl phosphate, rosin oil, oils and resins of ginger and a small quantity of an unidentified tar-like substance. No trace of the ordinary poisonous substances (mineral and alkaloidal) or of denaturants used in complete or specially denatured alc. was found. Tri-*o*-tolyl phosphate is obtained by washing the black lower layer described above first with water and then with approx. 5% NH_4OH. The residue is submitted to fractional distn. with high vacuum. The fraction coming off at the proper temp. is purified by redistn. and the phys. and chem. consts. are detd. Although it was certain early in this work that the tritolyl phosphate was present to the extent of about 2%, it almost escaped blame because reference books on therapeutics failed to list this ester as a poison or to mention that it would cause paralysis. A bibliography is appended. W. G. GAESSLER

Report of committee on drug market to the Pennsylvania pharmaceutical association annual convention. *Am. J. Pharm.* **102**, 575–82(1930).—A compilation of accumulated items of value and particularly those instances of adulteration and inferiority that are continually being met by those actually engaged in drug distribution, pharmaceutical mfg. and analytical research. W. G. GAESSLER

The tinctures of cinchona. I. A preliminary report. AARON LICHTIN. *Am. J. Pharm.* **102**, 583–90(1930).—The following method and menstruum are proposed as a result of studies in making a therapeutically active and stable prepn.: Moisten the bark with acetone and macerate for 24–48 hrs. Transfer the bark to a percolator and percolate with acetone until 5 cc. of the percolate mixed with 10 cc. distd. water and one drop of gelatin test soln. gives a faintly greenish, slightly opalescent liquid. Remove the bark from the percolator and dry it on a water bath at a temp. not exceeding 60°. Now prep. a tincture by the U. S. P. method using a menstruum of 4 vols. of alc. and one of water (78% alc.). In the receiving vessel place glycerol (7.5% of the vol. of tincture being prepd.) and complete percolation to the desired vol. Such a procedure, it is believed, yields a tincture with the cause of pptn. of the hydrolyzing tannins removed or almost completely so. A bibliography is appended. W. G. GAESSLER

Progress in tobacco chemistry and the production, manufacture and use of tobacco. RICHARD KISSLING. *Chem.-Ztg.* **54**, No. 84, *Fortschrittsber.* 95–8(1930). E. H.

Testing the efficacy of bactericidal and bacteriostatic reagents for use in specific chemotherapeusis. B. S. LEVINE. *J. Lab. Clin. Med.* **16**, 52–8(1930).—A review is made of the methods used in testing antiseptics for regulatory purposes and it is pointed out that in regulatory work specific conditions cannot be taken into consideration since these may be as variable and numerous as the individual cases to which any of the com. antiseptics is to be applied. In practical chemotherapeusis the investigator is concerned not so much with a particular reagent as with a definite set of conditions under which an infection flourishes. To meet such conditions rationally a generalized plan is outlined in which the isolation of the etiologic microörganism and the detn. of the p_H of the exudates of the infected area are of primary consideration. It is concluded also that for the present all application of an intravenous character, except in syphilis and the like, must be suspended until experimentation develops more hopeful prospects.

B. S. LEVINE

Pharmacognostic study on the cod-liver oil of Japanese Dorches ("Tara"). V. VI. K. KAWAI. *J. Pharm. Soc. Japan* **50**, 809–35, 843–50(1930); cf. *C. A.* **24**, 5427.

F. I. NAKAMURA

Chinese drug, "P'u-hwang." Y. KIMURA. *J. Pharm. Soc. Japan* **50**, 843–50 (1930); German abstr. 111–2.—K. isolated an oil (I) from *Typha angustata* (yield 10%). I (100 g.) when treated with 10% Na_2CO_3 soln., washed with Et_2O, and acidified with HCl gave (II) (yield 30 g.). II (20 g.) was dissolved in 3% alc. HCl (200 cc.), refluxed for 3 hrs., cooled, neutralized with Na_2CO_3 soln., washed with NaCl soln. and the alc. soln. removed and extd. with Et_2O, dried over $CaCl_2$, and fractionated at 12 mm., after removal of Et_2O, into the following constituents: **III** b. 193–6° (2 g.), **IV** b. 196–203° (9 g.), **V** b. 203–7° (2 g.), **VI** b. 207–210° (5 g.), **VII** b. 210° (1 g.), and residue (1 g.). III, IV and VI after sapon with 10% alc. KOH gave palmitic and stearic acids m. 62° and 69°, resp. The unsaponifiable part of I on treating with C_6H_5COCl gave *α-typhasterol benzoate* **VIII**, m. 148–8°, $[\alpha]_D^{15} - 23.56°$. **VIII** on hydrolysis gave *α-typhasterol*, $C_{27}H_{46}O$, m. 133–4°, $[\alpha]_D^{15} -59.83°$; *α-typhasterolacetate*, $C_{27}H_{45}OCOCH_3$ m. 119–20°, $[\alpha]_D^{15} -41.12°$.

F. I. NAKAMURA

Japanese peppermint oil. V. The high-boiling constituents of Japanese pepper mint oil (1). EINOSUKE SHINOZAKI AND T. NAGAZAWA. *Rept Osaka Ind. Research Lab. Japan* **11**, No. 9(1930); cf. *C. A.* **23**, 4298. -The high-boiling fraction (above 240°) was sapond. by the usual method and the following constituents were isolated: *l*-menthone, *l*-menthol, menthol, sesquiterpene and *dl*-sesquiterpene alc. **VI. The high-boiling constituents of Japanese peppermint oil (2).** *Ibid* No. 10.—The chief acid constituents of the high-boiling Japanese peppermint oil are, either in free or combined state, formic, acetic, isovaleric and caproic acids. Also in *J. Soc. Chem. Ind., Japan* **33**, Supp. binding 420,421 (1930).

F. I. NAKAMURA

Recent investigations on essential oils. ANON. *Bull. Imp Inst.* **28**, 281–4(1930). -*I. Petitgrain oil from Tanganyika.*—A sample of oil distd on Mkumbara Sisal Estate, Tanga, gave the following results: d_4^1 0.8957, $[\alpha]^{17.5} -5.95°$ n_D^{29} 1.460, acid value 0.7 ester value 159.4, esters (as linalyl acetate) 55.8%, soly. in 80% alc. at 15° turbid soln. even with 12 vols. These figures are generally similar to those of the com. S. American product, except as regards α which corresponds with that of French petitgrain. *II. Orange oils from South Africa.*—Three samples of oil of sweet (Valencia) oranges prepd. at Pretoria had phys. consts. corresponding to those of com. expressed sweet orange oils.

A. PAPINEAU-COUTURE

Sodium arsenate solution. E. V. CHRISTENSEN. *Arch. Pharm. Chem.* **87**, 327–34 (1930).—"Acidi Arsenicosi," 3.2 g. weighed to ±5 mg., and Na_2CO_3, 5.5 g., are dissolved in 500 cc. H_2O. To the cooled soln. is added 75 g. 3% H_2O_2, very slowly and with stirring. This is then brought to boiling and kept there for 15 min., again cooled and made up to 5 l. The prepn. contains 0.202% $Na_2HAsO_4.7H_2O$.

A. R. ROSE

Physicochemical analysis of a Eucalyptus globulus essential oil. T. BATUECAS, AND E. MORALES. *Anales soc. españ. fis. quím.* **28**, 1036–44(1930).—Eucalyptus oil is used as a flotation agent in Pb and Zn ore sepn. and in medicine. A Santander sample had d_4^{16} 0.9192, $d_4^{21.5}$ 0.9148, temp. coeff. of d. 0.00080, $n_D^{19.3}$ 1.4664, cineole content 56.5%, b. 168–190°, sol. in EtOH in all proportions, H_2O trace, f. p. below —20°, flash point 47.0°, heating value 9112–9705 cal., Engler viscosity between 20.8° and 52.6°, 1.18–1.06.

E. M. SYMMES

Tigogenin, a digitalis sapogenin. WALTER A. JACOBS AND ELMER E. FLECK. *J. Biol. Chem.* **88**, 545–50(1930).—Gitogenin from the crude saponin collected in the course

of the prepn. of cardiac glucosides from the leaves of *Digitalis purpurea* is contaminated by tigogenin. Sepn. of tigogenin is effected by petr. ether and proves to be $C_{28}H_{48}O_3$. It is a secondary alc. and yields ketone, $C_{26}H_{40}O_3$. It also yields monoacetate and monobenzoate. W. H. TIFFANY

Toilet creams and other toilet preparations. R. M. GATTEFOSSÉ. *Chemist and Druggist* **112**, 784-5(1930).—For superior face creams and face powders, naturally bleached, granular white beeswax is preferable to artificial compds., *e. g.*, stearates. Mix beeswax 5, starch 10, impalpably powd. kaolin 5, talc 5 parts, coloring and perfume to suit, then powder finely and sift. For cold cream a mixt. of beeswax 2, oil (a mixt. of white vegetable oil and petroleum oil) 20, glycerol 5–10, H_2O contg. a small quantity of powd. soap 10–20 parts may be used. Synthetic perfumes should be used only in conjunction with a more or less large % of natural essential oils or floral exts. S. W.

Ointment bases. Practical notes on the preparation of medicaments of this class and their absorption. HERBERT SKINNER. *Chemist and Druggist* **112**, 795(1930).—An ointment primarily suitable for *absorption* is the following modification of the Brit. Pharm. Codex *unguentum lanolini oleosum:* (*a*) Powd. tragacanth (No. 40) 2.5, (*b*) glycerol 20.0, H_2O 100.0, (*c*) hydrous wool fat 250, (*d*) oleic acid 30.0 parts. Stir *a* with *b* and H_2O to a smooth cream, heat to boiling and mix it into *c* previously mixed with *d*. Vegetable oils are good diluents, but coconut oil is regarded as a skin irritant. *Unguentum cetacei*, Brit. Pharm. **1914**, is an excellent *protective* ointment. As an ointment base for general use by the dermatologist, *unguentum paraffini*, Brit. Pharm. **1914**, in which white wax is replaced by twice its quantity of wool fat, may be employed. S. WALDBOTT

American indigenous drugs. S. B. PENICK, JR. *Chemist and Druggist* **112**, 846-7(1930).—The production, collection and marketing of botanical drugs in the U. S. are described; with photographs. S. WALDBOTT

Occurrence of kolacatechin in tormentilla root and in oak bark. II. P. CASPARIS AND K. REBER. *Pharm. Acta Helv.* **4**, 189-92(1929); cf. *C. A.* **24**, 5110.—Stabilized tormentilla root yields 0.14%, non-stabilized 0.08% of kolacatechin (*A*). Fresh stabilized oak bark yields 0.09%, com. official drug 0.06% of crystd. *A*. S. WALDBOTT

Examination and evaluation of urine in the apothecary shop (KAISER) **11B.** Some notes on lavender (ÉTABLISSEMENTS ANTOINE CHIRIS) **11D.** Cinchona (VAN DER WIELEN) **2.** Titrating Na arsenate solutions (CHRISTENSEN) **7.** Advancement in analytical investigation by means of ultra-violet rays (FRANK) **7.** Organo-antimony compounds. IV. Stibonic acids derived from certain local anesthetics (NIYOGY) **10.** Sulfonylchlorides (Brit. pat. 331,596) **25.**

Formulary of Manufactured Products and Industrial Specialties of Pharmacy. Paris Libraire Polytechnique de Ch. Béranger. 149 pp. F. 18. (Reviewed in *Bull soc. ind. de Mulhouse*, **96**, 552.)

Veterinary medicine. T. LEAHY. Brit. 332,464, Sept. 26, 1929. A remedy, stated to be suitable for hypodermic injection into cattle for the treatment of contagious abortion, rheumatism and "debility," comprises "lysol," liniment of iodine and turpentine.

Antiseptics and food-preservatives. T. SABALITSCHKA and NÄHRMITTELFABRIK J. PENNER A.-G. Brit. 331,274, March 28, 1929. See Fr. 678,165 (*C. A.* **24**, 3576).

Organo-arsenic compounds. PARKE, DAVIS & CO. Brit. 331,195, Dec. 22, 1928. Therapeutic products such as Na 3-amino-4-hydroxyphenylarsinic acid tetrathioglycolate, Na phenylglycinamide-4-arsinic acid tetrathioglycolate, Na 3-nitro-4-hydroxyphenylarsinic acid dithioglycolate, and the mono-cysteine derivs. of arsanilic acid and of phenylglycinamide-4-arsinic acid are prepd. by the interaction of an org. arsinic acid or salt with a mercaptocarboxylic acid or salt.

Imino ethers (intermediates for pharmaceutical compounds). K. F. SCHMIDT and P. ZUTAVERN. Brit. 331,947, April 19, 1929. Hydrazoic acid is allowed to act on carbonyl compds. such as cyclopentanone, acetone or cyclohexanone in the presence of catalytic acids such as HCl or H_2SO_4, P_2O_5, PCl_3, $POCl_3$, $ZnCl_2$ or thionyl chloride, and of ales., to produce imino ethers. Several examples are given.

Betaine thiocyanate. RUDOLF BERENDES and LUDWIG SCHÜTZ (to Winthrop Chemical Co.). U. S. 1,780,860, Nov. 4. This compd., colorless crystals m. 167° with decompn.) is suitable for use as a *therapeutic agent* in promoting elimination of urea and of NaCl and may be made by reaction of the base and acid.

Alkaline earth metal salts of arsenobenzene derivatives. RICHARD WERNER and ALBERT ROTHMANN (to Winthrop Chemical Co.). U. S. 1,779,649, Oct. 28. For the treatment of tumors and protozoan diseases, salts of Ca or other alk. earth metals are prepd. from starting compds. such as 3-ω-sulfomethylamino-3'-amino-4,4'-dihydroxyarsenobenzene, 3,3'-ω,ω'-disulfomethylamino-4,4'-dihydroxyarsenobenzene or other arsenobenzene derivs. contg. strongly acid groups, such as di-*p,p'*-glycinearsenobenzene or diformaldehydebisulfitearseno-(1-phenyl-2,3-dimethyl-4-amino-5-pyrazolone).

Skin cream for preventing sunburn. JACQUES RISLER (to Risler Corp. of America). U. S. 1,779,891, Oct. 28. Phosphorescent Zn sulfide is mixed with about 10 times its quantity of a cream base made by heating and mixing together stearic acid 170, glycerol 210, distd. water 569 and a 10% aq. NH_3 soln. 50 and adding to the mixt. when cold 1 part of violet essence.

Dentifrice. M. OGAWA. Brit. 332,142, Oct. 30, 1928. See Fr. 683,752 (*C. A.* **24**, 5113).

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Manufacture of chromic anhydride for electroplating. N. P. LAPIN AND L. N. GOLTZ. *Zhur. Prikladnoĭ Khim.* 3, 667–8(1930).—Dissolve 1 kg. $Na_2Cr_2O_7.2H_2O$ (technical) in 2.5 l. water, settle, decant and add 2.5 l. $H_2SO_4.H_2O$ with const. stirring. Leave for 24 hrs., decant the acid and dry the crystals by centrifuging. The yield is 82%, compared to 70% when HNO_3 is used. V. KALICHEVSKY

Manufacture of potassium nitrate and hydrochloric acid. V. I. NIKOLAEV. *Zhur. Prikladnoĭ Khim.* 3, 653–65(1930).—Chemically pure KNO_3 is obtained by mixing 74.56 g. KCl with 126 g. HNO_3 in 200–300 cc. water. The mixt. is distd. and the residue (101 g. KNO_3) dried at 110–20°. The fumes evolved can be used for conversion of further quantities of KCl into KNO_3 until the HCl/HNO_3 ratio is below 2.3 by wt. A com. installation is described, which permits complete utilization of HNO_3 and full recovery of HCl. V. KALICHEVSKY

Production of iodine from the red phyllophora of Black Sea. N. D. AVERKIEV. *Zhur. Prikladnoĭ Khim.* 3, 589–604(1930); cf. *C. A.* **17**, 3574.—The red phyllophora growing in the Black Sea contains more I than any other sea-weed in the world. The manuf. is described in detail and further development of the industry is urged. V. K.

Graphite in 1920. JEFFERSON MIDDLETON. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 41–9(preprint No. 4, published October 1, 1930). E. H.

Silica in 1929. ESTELLE R. PHILLIPS AND J. A. DORSEY. Bur. Mines, *Mineral Resources of the U. S. 1929*, Pt. II, 35–40(preprint No. 3, published September 30, 1930). E. H.

Inorganic and organic decolorizing agents. LEOPOLD SINGER. *Chem.-Ztg.* **54**, No. 84, *Fortschrittsber.* 98–108(1930).—A review. E. H.

The commerce of isinglass. HALE & SON. *Chemist and Druggist* **112**, 848–9 (1930).—A survey is made of the industry of which London is the com. center. With photographs. S. WALDBOTT

Desulfurizing gas (U. S. pat. 1,779,024) **21**. Fertilizer and $NaHCO_3$ (Brit. pat. 331,451) **15**.

Hydrocyanic acid and its use in fumigation. HANS LEHRECKE (to Roessler & Hasslacher Chem. Co.). U. S. 1,780,196, Nov. 4. A finely divided addn. product of HCN and iron chloride with an excess of the iron chloride is suitable for use by exposure to moist air for generating HCN. $CaCl_2$ or $MgCl_2$ also may be added. U. S. 1,780,197 relates to a similar mixt. with the further addn. of NaOCl which serves to generate cyanogen chloride as a warning agent. U. S. 1,780,198 describes stabilizing liquid HCN against polymerization or decompn. by adding $AlCl_3$ or other suitable inorg. compd. of a strong acid capable of hydrolysis under the conditions of storage of the material.

Evaporating caustic alkali solutions. R. M. WINTER and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 332,250, Jan. 16, 1929. Concn. is effected by evapg. in vessels formed of, or lined with, an alloy of Ni with Cu or Cr substantially free from Fe.

Alkaline earth molybdates. I. G. FARBENIND. A.-G. Brit. 331,472, Dec. 8, 1928. In the production of molybdates such as those of Mg or Ca, by treating fully roasted molybdenite with solns. or suspensions of the alk. earth hydroxides, the reaction is effected (preferably at the b. p.) in a soln. of but very slight alk. reaction, by gradual

addn. of the hydroxide. Excess of hydroxide (which causes formation of sol. molybdates) is avoided.

Cellular products from alkali metal silicates. J. W. BATTERSBY. Brit. 331,989, May 17, 1929. Readily sol. alkali silicates, in solid, colloidal, water-contg. form are heated to 200–500° to form cellular slabs or molded articles, the time of heating being regulated to produce the desired degree of expansion. Various fillers may be added and the operation may be effected in a mold and may be carried out in 2 stages with intermediate crushing.

Cyanamides. STICKSTOFFWERKE GES. (to N. Caro and A. R. Frank). Brit. 332,468, Oct. 1, 1928. In prepg. cyanamides of the alk. earth metals and of Mg as described in Brit. 279,812 (*C. A.* **22**, 3024) and Brit. 281,611 (*C. A.* **22**, 3497) by passing mixts. of NH_3 and CO over compds. of the metals which form oxides on heating, the reaction is carried out in the presence of substances which do not decompose NH_3 but act as catalysts for the water-gas reaction; Cu or Ag or their salts may be used for this purpose, and the reaction chamber may be formed of these metals. S compds. such as Na_2SO_4 may be added to avoid decompn. of NH_3 and the use of $CuSO_4$ with limestone or the like is mentioned.

Sulfates. O. KASELITZ and KALI-FORSCHUNGS-ANSTALT GES. Brit. 331,674, June 17, 1929. Concd. solns. of sulfates such as those of Na, Mg, Cd, Fe, Co, Ni or Mn, or the crystd. sulfates with or without addn. of previous mother liquors, are heated to temps. at which the soly. becomes practically nil (suitably about 200°), and the salt and liquor mixts. are sepd. without any appreciable reduction of pressure to obtain a product contg. little or no water of crystn. and the heat energy of the liquors is recovered.

Treating sulfate minerals such as alunite, etc. D. MAWSON. Brit. 331,552, April 4, 1929. Compds. such as alunite, jarosite, copiatite and carphosiderite are decompd. by treatment with NH_3, forming a sulfate soln. and leaving a residue contg. $Al(OH)_3$ or $Fe(OH)_3$. Free NH_3 in the soln. may be neutralized with H_2SO_4 or HNO_3 and sol. phosphate added if desired to produce *fertilizer salts* and alumina may be made from the residue.

Barium monoxide. G. T. SHINE. Brit. 331,878, Feb. 11, 1929. A retort construction is described suitable for the production of BaO from $BaCO_3$ and C.

Separating calcium and magnesium chlorides. ALBERT K. SMITH and CARL F. PRUTTON (to Dow Chemical Co.). U. S. 1,780,098, Oct. 28. In the purification of $CaCl_2$ contg. $MgCl_2$ in quantity less than that equiv. to a mol. proportion of 2:1, a soln. of the chlorides is concd. to effect crystn. of the hydrated double chloride $MgCl_2.2CaCl_2.6H_2O$ and the crystals formed are removed.

Slaking lime. WM. H. HENDERSON. U. S. 1,780,821, Nov. 4. An app. and mode of operation are described involving establishing an upwardly moving body of aq. liquid having a progressively decreasing regulated rate of flow, adding, countercurrentwise, quicklime contg. hydratable and sol. solids and an insol. residue in regulated amounts and at a regulated rate, thoroughly agitating and promoting hydration and soln. of the hydratable and sol. substances in a lower zone, effecting hydraulic segregation of the insol. residue and removing the latter at the base of the app. and removing aq. liquid and suspended solids at the top.

Carbon disulfide. IMPERIAL CHEMICAL INDUSTRIES, LTD., W. B. FLETCHER, T. S. WHEELER and J. MCAULAY. Brit. 331,734, Aug. 21, 1929. Hydrocarbons such as CH_4 are heated with S vapor at temps. above 1100°, at which no C oxysulfide is formed. Hydrocarbon-contg. gases such as coal gas, coke-oven gas or gases from hydrogenation of carbonaceous material may be used as starting material and may be dild. with H or other inert gas. Various details of procedure are described.

Cyanogen chloride. JOHANN P. SCHMITTNÄGEL (to National Aniline & Chemical Co.). U. S. 1,779,984, Oct. 28. NaCN is treated with Cl in the presence of an inert solvent such as CCl_4 or $C_2H_2Cl_4$ and EtOH. A temp. of about 0° is suitable.

Activated ferric oxide. G. E. SEIL. Brit. 332,259, April 15, 1929. Ferruginous material such as iron borings, iron ore or "aniline sludge" is mixed with an alk. material such as "fished salt" or Na or K carbonate, either dry or in concd. soln., and the mixt. is heated, the alkali ferrite formed is quenched and ground, the alk. soln. is filtered off and ferric oxide remains which may be used in *gas purification*, as a *filter medium*, *accelerator with rubber*, or as a *catalyst*, after washing out alk. compds.

Magnesium sulfate from waste water of artificial silk factories, etc. E. ROPOLFO. Brit. 331,648, May 21, 1929. Waste waters which may contain $MgSO_4$, Na_2SO_4, $ZnSO_4$ and H_2SO_4 are treated with milk of lime to ppt. $CaSO_4$, $Mg(OH)_2$ and $Zn(OH)_2$ (suitably after preliminary neutralization of free H_2SO_4 with dolomite or calcined dolomite); the soln., freed from the ppt., is evapd. to cryst. Na_2SO_4; the ppt. is dispersed in water,

treated with CO_2 at a temp. of 50–60° to form a soln. of $MgSO_4$ up to a concn. of 20° Bé., and the $MgSO_4$ is crystd. from the sepd. soln.

Potassium nitrate. P. HÖFER and KALI-FORSCHUNGS-ANSTALT GES. Brit. 332,359, June 13, 1929. KNO_3 is formed by reaction of KCl on the nitrate of a readilyhy drolyzable metal such as that of Al or Fe, and the hot mixt. may be cooled to sep. KNO_3. The mother liquor is evapd. with evolution of HCl, either until nitrous gases begin to escape or until most of the Cl has been expelled from the soln.; water, KCl and HNO_3 or N oxides are added to restore the original concn., the soln. is cooled, KNO_3 is sepd. and the operations are repeated.

Potassium nitrate and chloride and sodium nitrate. I. G. FARBENIND. A.-G. Brit. 331,236, March 25, 1929. Salt mixts. contg. these compds. are treated for their sepn. with liquid NH_3 which may contain NH_4NO_3 to avoid use of high pressures and to vary the soly. of the salts. Various details are given. Cf. *C. A.* **24**, 4361.

Purifying zinc sulfate solutions. ROYALE H. STEVENS, GERALD C. NORRIS and WM. N WATSON (to Rhodesia Broken Hill Development Co.). U. S. 1,778,087, Oct. 21. Metallic impurities such as Cu, Cd, Ni and Co are pptd. by treating the soln. with Zn xanthate or other compd. of a deriv. of dithiocarbonic acid of the type MS.CS.OR, in which M is a radical, the compd. of which is appreciably sol. in the Zn soln. under treatment, while R is an org. radical.

Purification of zinc sulfate solutions. SOC. MINIÈRE ET MÈTALLURGIQUE DE PENARROYA. Brit. 331,886, Jan. 30, 1929. See Fr. 683,810 (*C. A.* **24**, 5116).

Separating arsenic, antimony and tin from their mixed salts. CHARLES A. HEBERLEIN (to American Smelting and Refining Co.). U. S. 1,779,272, Oct. 21. In sepg. Na stannate from a mixt. with other salts including Na arsenate, the mixt. is treated with water in such quantity and at such temp. that only part of the Na stannate will dissolve to insure complete insoly. of the other salts. Cf. *C. A.* **24**, 1708.

Mercury recovery from aqueous sludges. R. RILEY, S. W. ROWELL and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 332,106, Aug. 21, 1929. Sludges obtained in prepg. acetaldehyde from C_2H_2 with Hg salts as catalysts are treated with water and Cl, the $HgCl_2$ soln. formed is sepd. and the Hg preferably is pptd. as oxide, which may be dissolved in dil. H_2SO_4 for further use as a catalyst. Hg remaining in the sludge may be recovered by sublimation.

Carbon black and lamp black. G. C. LEWIS. Brit. 331,821, April 4, 1929. A hydrocarbon-contg. gas such as natural gas is heated to a temp. (suitably 600–850°, depending on the character of the gas) at which the hydrocarbon constituents react chemically but without the production of free C, the resulting mixt. is cooled by expansion to a temp. not below that at which any constituent condenses out, and the resulting mixt. is subjected to incomplete combustion. The heating app. may have Ni or Fe walls, and various details of the app. and operation are described.

Substantially pure finely divided carbon. DANIEL GARDNER. U. S. 1,780,154, Nov. 4. In obtaining substantially pure impalpable C, impure material such as beech or oak wood charcoal is reduced to impalpability, boiled at ordinary pressure with caustic alkali soln. of high concn. to solubilize any silica in the material and to render lime, magnesia, alumina, Ti oxide and the like amenable to extn. with hot HNO_3, solids are sepd. from the alkali soln. and washed with water and the washed solids are further treated with strong HNO_3 at an elevated temp., the solid product is sepd. and again washed, again reduced to a state of impalpability and heated to about 1000–1300° to expel org. impurities and eliminate moisture. The product is suitable for use as a *pigment*.

Tunnel kiln suitable for activating carbon. OSCAR L. BARNEBEY and MERRITT B. CHENEY. U. S. 1,778,747, Oct. 21. Structural features.

Catalysts for ammonia oxidation. I. G. FARBENIND. A.-G. Brit. 331,728, Aug. 17, 1929. A Pt group metal (which may be deposited on a support such as porcelain balls) is provided with a coating of finely divided Rh or a mixt. of Rh with another Pt group metal.

Catalysts for oxidation of toluene, etc. GAS LIGHT & COKE CO., W. G. ADAM, W. V. SHANNON and M. CUCKNEY. Brit. 331,535, Jan. 29, 1929. Catalysts such as a mixt. of Fe vanadate and Fe oxide are formed into a coherent mass with a small proportion of asbestos fibers serving as a binder. The material may be formed into rods and then broken up into short cylinders.

Apparatus for exothermic catalytic gas reactions. HANS HARTER. U. S. 1,779,092, Oct. 21. An app. suitable for *synthesis of* NH_3 or oxidation of NH_3 to produce HNO_3 comprises a pressure-sustaining tube of considerable length enclosing a plurality of elongated reaction chambers having nearly the same cross-section as the tube and

arranged in a continuous row, with means for distributing the reagent gases over and withdrawing the reaction products from the chambers in parallel.

Apparatus for exothermic catalytic gas reactions. A. O. JAEGER (to Selden Co.). Brit. 331,468, Dec. 22, 1928. An app. suitable for the *production of* SO_3 and which also may be used in *org. oxidations*, NH_3 *purification, reductions, hydrogenations, condensations,* the *water-gas process* or *HCN synthesis* comprises one or more layers of catalyst cooled by the reaction gases, followed by one or more layers of catalyst cooled by means other than the reaction gases issuing from the first-mentioned layer or layers, as by an independent cooling medium or by preliminary contact with the reaction gases. Various structural details of outer and inner tubes, etc., are described. Cf. *C. A.* **24**, 532.

Condensation products from glycerol and sebacic acid, etc. HERMAN A. BRUSON (to Resinous Products & Chemical Co.). U. S. 1,779,367, Oct. 21. Condensation of glycerol with adipic or sebacic acids results in products of soft rubbery character suitable for use with nitrocellulose or other cellulose esters for forming compns. of good flexibility, elasticity and toughness. Other acids such as pimelic, suberic and azelaic acids yield similar condensation products with glycerol. Condensation is effected in three stages: (1) formation of a thin sirup, sol. in acetone; (2) formation of an intermediate product, a tacky, rubbery mass sol. in acetone or EtOAc but insol. in C_6H_6; and (3) a final product, a soft, flexible, elastic and very tough solid, insol. in the common org. solvents.

Slag product suitable for molded articles. SAMUEL F. WALTON (to Exolon Co.). U. S. 1,781,204, Nov. 11. Finely divided slag with a siliceous glaze including an oxide of definite color is used with a binder of phenolic resin.

Homogeneously porous meerschaum-like artificial products. KURT RIPPER (to Kunstharzfabrik Fritz Pollak G. m. b. H.). U. S. 1,779,047, Oct. 21. Condensation products such as those formed from urea and CH_2O are dild. with a large proportion of a dispersion medium but short of the quantity which would prevent gelatinization and gelatinization is then effected at a temp. not substantially above 50°, followed by volatilization of the dispersion medium which takes place without substantial diminution of volume so that a uniform porosity of the mass results.

Waterproof adhesive. JAMES B. MULLADY. U. S. 1,779,613, Oct. 28. Na silicate 6–10 oz. is mixed with water 3 bbls. and during the mixing there is gradually added a mixt. formed from casein 1 lb., hydrated lime 3.25 oz. and borax 2–4 oz.; the mixt. is stirred until it begins to thicken, allowed to stand for about 20 min and again stirred for about 10 min.

Adhesive or size. J. TAYLOR and A. V. KELLER. Brit. 331,428, Aug. 29, 1929. After condensing urea, thiourea or substituted ureas or their derivs. with a solid anhyd. polymer of CH_2O in the presence of water or steam, the resulting soln. is concd. at not above 90° to obtain a transparent gel which may be used in soln. or made into wafers or dried and powdered, with or without addn. of various auxiliary or modifying substances.

Causing adhesion of articles such as parts of shoes. JAMES CAVANAGH (to United Shoe Machinery Corp.). U. S. 1,779,368, Oct. 21. The faces of the articles to be united are coated with rubber-latex cement, the coatings are allowed to dry until they are non tacky and the coated faces are then pressed together.

Preparing a decolorizing clay. WALTER S. BAYLIS (to Filtrol Co. of Calif.). U. S. 1,781,265, Nov. 11. An initial batch of an activatable clay is treated with a highly ionized inorg. acid such as H_2SO_4 and after this a larger quantity of raw activatable clay is added and the mixt. is subjected to a temp. sufficient to eliminate substantially all water of crystn. and free acid from the clay.

Piezoelectric crystals. C. W. HANSELL and MARCONI'S WIRELESS TELEGRAPH CO., LTD. Brit. 332,451, Sept. 12, 1929. Wear of a piezo elec. crystal is reduced by passing a stream of gas between the crystal and its electrodes, thus reducing or eliminating contact and maintaining the temp. of the crystal const. by regulating the temp. of the gas. Various details of app. and procedure are described, and air, H or He may be used in a closed-circuit system.

Machinable composition nonconductive of electricity. MARC DARRIN (to F. N. Burt Co., Ltd.). U. S. reissue 17,867, Nov. 11. Reissue of original pat. No. 1,644,711 (*C. A.* **21**, 4036).

Tarnish-resisting silverware. DANIEL GRAY, RICHARD O. BAILEY and WM. S. MURRAY (to Oneida Community, Ltd.). U. S. 1,779,809, Oct. 28. A metal such as Sn, Al, Ca, Mg, Bi, Pd, Zn or Sb having a shielding action with regard to tarnishing is absorbed in the surface portion of the silver, as by alternate electrodeposition and heating together of the metals. Cf. *C. A.* **24**, 3207, 5119.

Dialyzing and pervaporating membranes. PHILIP A. KOBER. U. S. 1,779,942, Oct. 28. A cellulose deriv. such as nitrocellulose and a protein material such as gelatin

are dissolved in a common solvent, *e. g.*, glacial HOAc, and a membrane is formed from the soln. by removing the solvent, and the membrane is treated with a liquid such as water.

Film-forming surfaces. G. FRENKEL. Brit. 332,254, Feb. 18, 1929. A film-forming surface is prepd. by coating a drum or band (which may be formed of metal) with a plastic compn. such as a cellulose acetate compn., synthetic resin, rubber or gelatin and applying over this a smooth metal coating (which may be produced by spraying). Various details and modifications of compns. and procedure are described.

Opaque films. NON-INFLAMMABLE FILM CO., LTD., and D. J. P. PHILLIPS. Brit. 331,214, March 25, 1929. Two films are superposed, one of which contains finely divided metallic powder such as Au or Al while the other contains an ordinary filler or opaque coloring material such as ZnO. Cellulose esters or ethers or regenerated cellulose may be used and various details and examples are given.

Films for wrapping, etc. G. FRENKEL. Brit. 332,256, Feb. 18, 1929. A metal film is formed or placed between layers of cellulose acetate compn or similar dielectric material. Various modifications of manuf. are described.

Transfers. E. HENTSCHEL. Brit. 331,761, Oct. 18, 1928. A transfer for use with dry heat to effect detachment of the design from its backing with simultaneous rendering of a coating on the design adhesive from the heat has the design formed with a film of cellulose ester which may be used with a backing of paper coated with wax, printed with a collodion bronze powder mixt. or the like or overlaid with a stamped-out colored cellulose ester film. A thin film of resin such as dammar or mastic, which becomes adhesive when heated, is then applied.

Transfers. ARTHUR J. LAWS. U. S. 1,780,021, Oct. 28. A removable base sheet of paper is coated with a water-sol. adhesive substance and a nitrocellulose material is applied to the coated surface, the material is printed upon and the film and printed matter are coated with a second soln. such as a varnish and pigment mixt. having no solvent properties with respect to either the first film or printed matter, to cause ink pigments to be engaged between the transparent first coating and the substantially opaque second coating (the second coating forming a permanent part of the transfer).

Sugar solutions derived from peat. I. G. FARBENIND. A.-G. Brit. 332,235, March 11, 1929. Sugar solns. obtained by acid hydrolysis of peat are freed from humous substances by treating the solns. with voluminous non-alk. agents of large superficial area such as inorg. oxides or hydrates having a gel structure or charcoal or metal salts which decompose with water only partially and give water-sol. salts with humic acids such as Fe chlorides or Mn salts or Al sulfate, Pb acetate, active carbon, colloidal silicic acid or alumina. The material may be adjusted to a p_H of 5 to 8 and odorous substances may be removed by Cl, SO_2, CH_2O or "chloramin." The purified solns. may be used for *cultivation of microörganisms.*

Etched printing surfaces. J. DREYER and J. MYKLEBUST. Brit. 332,045, July 1, 1929. In forming flat positive printing forms for offset printing, an impression is made in greasy ink upon a thin Zn, Al or other suitable metal plate, which is then etched and may be used either for offset printing direct or as a master plate for making transfers for producing duplicate plates.

Intaglio printing surfaces. R. KLINGER. Brit. 332,276, April 16, 1929. Parts of a metallic surface to be etched are provided with a granulation which is etched into the depth by protecting the sides of the grain while leaving the apexes as well as the bottoms of the spaces between the individual grains exposed to the action of the etching medium. Various details of procedure involving use of an Fe chloride soln. as etching medium are described.

Printing plates. A. R. TRIST. Brit. 331,220, March 25, 1929. A plate with mercurized non-printing areas is prepd. from a plate with an electrolytically deposited Ni layer on Cr over a Cu base, a colloidal resist being formed on the Ni, the exposed parts of which are dissolved by an etching fluid adapted to harden the colloidal layer, followed by dissolving the exposed Cr by a fluid which will not affect Ni, replacing the Cr by an amalgam of a noble metal, and final removal of the remaining Ni and colloidal material. Numerous details and modifications of procedure are described

Pastel receiving surface. HERMAN E. BRAEG (one-third to Bernard J. Preston). U. S. 1,780,113, Oct. 28. A base of fibrous material such as paper, cloth or cardboard is provided with a coating of a monochromatic mixt. comprising SiC, garnet and quartz powder of uniform depth.

Backing for stencil sheet. SHINJIRO HORII. U. S. 1,780,391, Nov. 4. A backing sheet for a dry-process stencil sheet is formed of a firm stiff paper treated with a coating

compn. including a non-drying oil and a hardening material such as a wax, copal or ester gum.

Emulsified compositions such as those for making waterproof sheets, etc. LESTER KIRSCHBRAUN. U. S. 1,781,645, Nov. 11. Fibrous pulp is mixed with a normally adhesive bituminous waterproofing material dispersed in an aq. vehicle contg. soap and rendered non-adhesive by incorporation with an agent such as colloidal clay in quantity less than would substantially impair the waterproofing properties of the bituminous waterproofing material; a sheet is formed from the mixt. and is dried to cause the bituminous material to resume its adhesive condition and waterproof the fibers.

Sound records. RADIO CORP. OF AMERICA AND GRAMOPHONE CO., LTD. Brit. 331,278, April 3, 1929. A master, carrying ink or other material, is prepd. from a sound record to be duplicated and is used for printing a duplicate sound record upon a suitable carrier by a printing process which may involve transfer of the ink, etc. Various details of compns. and procedure are given.

Detergent. WARREN T. REDDISH (to Twitchell Process Co.). U. S. 1,780,144, Oct. 28. An oil-sol. mineral oil sulfonate is chemically combined with a stable water-sol. amine such as triethanolamine.

Liquid of low freezing point suitable for use in automobile cooling systems. OTTO JORDAN (to I. G. Farbenind. A.-G.). U. S. 1,780,927, Nov. 11. A monoalkyl ether of a glycol such as the methyl ether of ethylene glycol is mixed with water. Glycols, glycerol, alcs., etc., may also be added.

Liquid for use in hydraulic brake systems. ROBERT M. BAGLEY (to R. M. Hollingshead Co.). U. S. 1,779,460, Oct. 28. Ethylene glycol mono-ethyl ether is used with about an equal quantity of a relatively inert oily substance sol. therein, such as castor oil and glycerol.

Composition for making lines on tennis courts, roads, etc. W. T. BELL and J. F. BENNETT. Brit. 331,207, March 23, 1929. A filler of ground porcelain or pottery is mixed with a binder of white cement, plaster of Paris and water to form a plastic paste, or a dry mixt. may be formed and moistened after rolling in place.

Preserving cut flowers. I. G. FARBENIND. A.-G. Brit. 332,278, April 17, 1929. There is added to the water used a sol. salt of Ag or Cu such as the nitrate, sulfate or acetate of Ag, which acts as an antiseptic, and a sugar or polyhydric alc. and other nutrients and porous materials such as silica gel also may be added, and mixts. for addn. to the water may be prepd. in tablet form. Lactic acid, dihydroxyacetone, asparagine and salts of K, NH_4 and Mg are among the nutrients mentioned which may be used.

Device for distributing fire-extinguishing foam. HANS BURMEISTER (to Pyrene-Minimax Corp.). U. S. 1,780,168, Nov. 4. Structural features.

Apparatus for producing fire-extinguishing foam from two dissimilar liquids such as aluminum sulfate and sodium bicarbonate solutions. PAUL W. PRUTZMAN. U. S. 1,781,298-9-300, Nov. 11. Various structural features of app. adapted for mounting on a motor vehicle.

Devices for producing fire-extinguishing foam from water and pulverulent chemicals. JAMES A. MCCRACKEN. U. S. 1,781,292-3-4-5, Nov. 11. Al sulfate, $NaHCO_3$ and licorice may be used with water in the app.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E BARTON, C. H. KERR

Specific heat, thermal conductivity and adiabatic temperature change in the softening range of glasses. G. TAMMANN AND H. ELSNER V. GRONOW. *Z. anorg. allgem. Chem.* 192, 193–209(1930).—The specific heat of Se glass increases sharply at 30° from 0.09 to 0.13, and that of rosin not so sharply in the interval 26–30° from 0.3 to 0.4. The thermal cond. of Se glass diminishes rapidly from 29° to 34°, that of rosin at about the same range, and salicin at 44–47°. The change in temp. on rapid compression and expansion was measured at several temps.; the difference between the observed and calcd. values was interpreted as showing that slow processes are at work in the highly viscous substances. T. H. CHILTON

The dependence upon temperature of some elastic properties in the softening range of glasses. G. TAMMANN AND R. KLEIN. *Z. anorg. allgem. Chem.* 192, 161–78 (1930).—The rebound of a ball dropping on a plate changed sharply in the softening range of rosin, salicin and phenolphthalein, but the temp. of sharp change was not

identical with that for the change of other properties, and varied with the height of fall. The hardness measured by observation of the width of the depression caused by a loaded sphere also changed, but the temp. where it begins to decrease was lower than that at which brittleness disappears. The appearance of cracks produced by scratching with a steel point is characteristic, and may be used to det. the change from a glass to a viscous liquid, but the effect is dependent on the angle, speed and loading of the point. T. H. CHILTON

The behavior of glasses in their softening interval. G. TAMMANN. *Z. Elektrochem.* **36**, 665-75(1930); cf. *C. A.* **24**, 4908.—A summary of previous work. L. W.

Chemical and mineralogical composition of stalactites from two glass factories. D. S. BELYANKIN. *Bull. acad. sci. union rep. soviet. social*, Classe sci. phys.-math., **1930**, 257–65(summary in French); cf. *C. A.* **24**, 477.—Stalactites from the Vélikodvorsky and the Droujnayat-Gorka plants were studied. Chem. analyses of the furnace lining (Dinas brick), the glass and the stalactites, resp., of the former were: SiO_2 93.82, 71.87, 90.35; (Al, Fe)$_2O_3$ 2.43, 2.03, 2.33; MnO —, 0.13, 1.19; MgO 0.09, —, 0.15; CaO 2.38, 14.69, 3.19; (Na, K)$_2$O 0.12, 11.58, 2.79%. For the latter the values were: SiO_2 93.73, 73.18, 88.01; (Al, Fe)$_2O_3$ 4.75, 1.84, 2.76; CaO 1.48, 8.20, 6.77; (Na, K)$_2$O —, 16.78, 2.19. The stalactites from the former were composed of tridymite, cristobalite and monoclinic pyroxene; those from the latter were composed of tridymite and pseudowallastonite. Four photomicrographs are reproduced. W. L. HILL

Color tinge of glass without decolorizing agent. HANS JEBSEN-MARWEDEL AND ALFRED BECKER. *Sprechsaal* **63**, 874-8(1930).—The color tinge of glass, so far as it depends upon the Fe content, is principally a function of the O_2 pressure of the batch. C. H. LORIG

The solubility of bottle glass in water as a function of time and temperature. CARL SCHMID. *Sprechsaal* **63**, 759-62(1930).—The soly. in H_2O of a bottle glass contg. SiO_2 62.2, CaO 13.3, Al_2O_3 9.8, Fe_2O_3 0.9, Mn_3O_4 0.3, Na_2O 9.8, and K_2O 3.6% was detd. over a temp. range of 25–90°. No marked soly. of the glass was observed after 3 days in H_2O at 90°. Variations in soly. were observed from changes in elec. cond. of the H_2O. Glass of the above compn. is highly resistant to H_2O. C. H. LORIG

The determination of the limiting temperature for the cooling of machine-made bottles during the annealing in the Simplex-Lehrs system. A. I. SHILIN. *Sprechsaal* **63**, 893-9(1930).—The temp. drop during processing on the foretable of the Lynch machine on the av. amounts to 12° per sec. at the bottom and 23° per sec. at the upper part of the bottles. The actual temp. drop on the conveyor is never more than 2° per sec. A large amt. of data and 15 curve diagrams are given. C. H. LORIG

An improved method for determining the tensile strength of unfired clays. STUART M. PHELPS AND VANCE CARTWRIGHT. *J. Am. Ceram. Soc.* **13**, 845-9(1930).—The test piece, which is cast or pressed, is cylindrical and has a collar of low-melting alloy cast around each end for proper gripping. C. H. KERR

Transverse strength of ball clay-sand and ball clay-flint mixtures. L. P. COLLIN. *J Am. Ceram. Soc.* **13**, 876-83(1930).—Tests of dry transverse strength on 30 ball clays, with 50% each of ball clay and flint, and ball clay and standard silica sand showed that flint mixts. gave the more consistent results. Flint or other fine-grained non-plastic should be used instead of standard silica sand in a revised tentative method of detg. dry transverse strength. The method of forming test bars should be improved and the rate of applying load should be further studied. C. H. KERR

Altering the properties of heavy clays by the use of electrolytes. TAJAMUL HUSAIN. *J. Am. Ceram. Soc.* **13**, 805-16(1930).—Tannic acid, HCl, Na_2CO_3 and $CaCl_2$ were tried. The results varied greatly with different clays. Data are given in great detail. C. H. KERR

Stiff-mud die troubles. ELLIS LOVEJOY AND H. B. HENDERSON. *J. Am. Ceram. Soc.* **13**, 787–93(1930). C. H. KERR

The relation of Brinell hardness and transverse strength to the compressive strength of building brick. J. W. MCBURNEY. *J. Am. Ceram. Soc.* **13**, 823-30(1930).—Neither relationship is sufficiently exact to permit calcn. of compressive strength. C. H. KERR

Recent patent literature on the manufacture of silica brick. FRIEDRICH REINHARDT. *Tonind.-Ztg.* **54**, 1373(1930). F. O. A.

A unit analysis of feldspar. E. E. PRESSLER. *J. Am. Ceram. Soc.* **13**, 850–5 (1930).—The sample is sintered at 850° for 2 hrs. The alkalies are detd. on the filtrate from the insol. group. C. H. KERR

Correcting tenderness of a shale by chemical treatment. HAROLD E. SIMPSON. *J. Am Ceram. Soc.* **13**, 817-22(1930).—Use of H_2SO_4, up to 10% concn., increased the

dry modulus up to 250% but the color was bleached. Use of 0.25% HCl and 0.25% tannic acid increased the dry modulus 42 and 72%, resp. Org. binders, as Bindex and glutrin, gave 100% increase. Na_2CO_3 (2%) and $BaCO_3$ (1%) showed 60 and 45% increase, resp. Molasses plus yeast improved machining and green strength. Finer grinding (to pass 28-mesh) and aging (1 week) increased the dry modulus 76%. Bush Creek Shale was used in the tests. C. H. KERR

Vapor glazing and color flashing of Pre-Cambrian shales. H. L. LONGENECKER. *J. Am. Ceram. Soc.* **13**, 794–804(1930).—Pre-Cambrian shales will take a satisfactory Zn vapor glaze and are suitable for color flashing to produce brown, purple and black bricks. Procedures at the Seaboard Shale Brick and Tile Co., Monroe, N. C., are described. C. H. KERR

Discoloration in burnt kaolin. BERNHARD NEUMANN. *Sprechsaal* **63**, 757–8 (1930).—Discolorations appear as light gray-blue, shell-like zones and yellow to brown-like bands. The former results from the pptn. of C during the decompn. of CO penetrating the kaolin; the latter results from the concn. of Fe_2O_3 in these areas. C. H. LORIG

The use of waste gypsum molds. PETER P. BUDNIKOV AND V. M LEZHOEV. *Sprechsaal* **63**, 717-21(1930).—See *C. A.* **24**, 3336. C. H. LORIG

Body calculations by graphical means. JOSEPH WOLF. *Sprechsaal* **63**, 657–9, 679-81, 697-700(1930).—Mineral compns. of ceramic bodies are calcd. graphically by (1) rectangular coördinates or (2) equilateral triangles. C. H. LORIG

A study of pan grinding. J. W. MELLOR. *Trans. Ceram. Soc.* (England) **29**, 271-9(1930). H. F. K.

Progress in ceramics in the year 1929. M. MIELDS. *Chem.-Ztg.* **54**, No. 84, *Fortschrittsber.* 86 95(1930). E. H.

Air conditioning in ceramics. H. B. MATZEN AND C. E. PARMELEE. *J. Am. Ceram. Soc.* **13**, 856 64(1930). C. H. KERR

The modern porcelain and china plant. HEINZ TIVES. *Sprechsaal* **63**, 737–41 (1930). C. H. LORIG

The cause and prevention of certain brown stains on semivitreous tableware. G A. LOOMIS. *J. Am. Ceram Soc.* **13**, 871 3(1930).—Stains were due to reduction of Fe in the sand in which the ware was imbedded during the bisque burn. C. H. KERR

Forming pressure of dry-pressed refractories. II. The effect of pressure variations on fired properties. RAYMOND E. BIRCH. *J. Am. Ceram. Soc.* **13**, 831–44(1930); cf. *C. A.* **24**, 2565. C. H. KERR

Woodall-Duckham continuous circular tunnel kiln. ARTHUR N. TARRANT *Trans. Ceram. Soc.* (England) **29**, 280-7(1930). H. F. K.

A rapid-fire tunnel kiln designed for small production. A L. DONNENWIRTH. *J. Am. Ceram. Soc.* **13**, 865–70(1930).—The firing time is 2 hrs. The temp. is cone 17. C. H. KERR

Methods for the determination of the firing range of vitreous enamels used in wet-process enameling. C. J. KINZIE. *J. Am. Ceram. Soc.* **13**, 896–9(1930). C. H. KERR

Observations of causes of inconsistent results in commercial fineness tests of porcelain enamels. H. G. WOLFRAM. *J. Am. Ceram. Soc.* **13**, 884–6(1930). C. H. K.

Causes for hair crack formation in iron enamel. R. WEINIG. *Sprechsaal* **63**, 723 4(1930). C. H. LORIG

Aluminum fluoride in cast iron enamels. ALAN L. GORMLY. *J. Am. Ceram.* 13, 900-2(1930).—AlF_3 can be used to replace cryolite. C. H. KERR

A comparison of results obtained with an impact machine [for sheet iron and cast iron enamels]. RICHARD H. TURK. *J. Am. Ceram. Soc.* **13**, 887–93(1930).—The old method of striking the enamel with or against a hard object is unreliable. A pendulum type of machine, able to deliver a 4 ft.-lb. blow, was used. The reverse side, not the test side, was subjected to the blows. Data are given. C. H. KERR

The development and use of a simple consistency pipet for use in the adjustment and control of enamel slips. C. J. KINZIE AND C. H. COMMONS. *J. Am. Ceram. Soc.* 13, 894–5(1930).—The pipet is described with structural details. C. H. KERR

Notes on casting slip. LESLIE SAMPLE. *J. Am. Ceram. Soc.* **13**, 874–5(1930).—Viscometer control proved unreliable. The "cup" casting test was used instead. C. H. KERR

Physiological and chemical experiments with ultra-violet rays through glass (VALENTIN) **11A. Electrical porcelain** (GILLETT) **4.**

Apparatus for feeding mold charges of molten glass. WM. T. BARKER, JR. (to Hartford-Empire Co.). U. S. 1,780,550, Nov. 4. Structural features.

Apparatus for feeding mold charges of molten glass. KARL E. PEILER (to Hartford-Empire Co.). U. S. 1,781,340, Nov. 11. Structural features.

Apparatus for delivering mold charges of molten glass. LEONARD D. SOUBIER (to Owens-Illinois Glass Co.). U. S. 1,778,775, Oct. 21. Structural features.

Apparatus for delivering mold charges of molten glass. UNITED GLASS BOTTLE MANUFACTURERS, LTD., and T. C. MOORSHEAD. Brit. 332,053, July 9, 1929. Structural features.

Apparatus for sheet glass manufacture. ENOCH T. FERNGREN (to Libbey-Owens-Ford Glass Co.). U. S. 1,781,452, Nov. 11. Structural features.

Forming blown glassware. ROBERT J. BEATTY (to Federal Glass Co.). U. S. 1,781,565, Nov. 11. App. and various details of operation are described.

Forming stemmed and footed glassware. WILBERT S. WILLIAMS and DAVID L. MIDDENDORF (to Federal Glass Co.). U. S. 1,778,743, Oct. 21. Mech. features.

Conveyor for passing bottles or other glassware through annealing leers. PERCY Q. WILLIAMS. U. S. 1,778,742, Oct. 21. Structural and elec. control features.

Forming and annealing glass sheets. CHARLES HEUZE (to American Bicheroux Co.). U. S. 1,780,590, Nov. 4. Mech. features.

Roller-way leer for annealing glass sheets. SIMPLEX ENGINEERING CO. Brit 331,927, April 13, 1929. Structural features.

Glassware-annealing leer. RICHARD LAFRANCE (to Owens-Illinois Glass Co.). U. S. 1,778,763, Oct. 21.

Glass transmitting ultra-violet rays of sunlight. BERNARD LONG (to Soc. anon. des manufactures des glaces & produits chimiques de Saint-Gobain). U. S. 1,779,176, Oct. 21. Glass is formed contg. less than 0.02% ferric Fe and contg. Mn 0.05–0.50%.

Colored glass. F. WEIDERT (to Deutsche Gasglühlicht-Auer-Ges.). Brit. 320,946, Dec. 15, 1928. See Fr. 684,705 (*C. A.* **24**, 545).

Glass insulators. DAVIDGE H. ROWLAND (to Locke Insulator Corp.). U. S. 1,780,246, Nov. 4. In making insulators of glass with permanently attached metal suspending devices, the glass is molded about the suspension device and an elec. current is passed through the latter to heat it during the molding and until the glass has set. Various structural details are described.

Laminated glass sheet material. H. A. GARDNER. Brit. 332,234, March 11, 1929. Sheets of glass are united by a non-brittle binder comprising a synthetic resin of the toluene-sulfonamide-aldehyde type. Various details and examples are given.

Uniting sheets of glass and cellulose derivatives. T. W. HOLT. Brit. 332,385, July 4, 1929. Mech. features.

Uniting glass sheets with sheets of celluloid or similar material. JAMES H. SHERTS and ROBERT E. HAMILL (to Duplate Corp.). U. S. 1,781,084, Nov. 11. The assembled sheets are submerged in a bath of pyroxylin solvent and the temp. is raised to a point at which the plastic sheets are softened and pressure is applied to the bath. App. is described.

Glass-tank furnace. GEORGE W. BATCHELL. U. S. 1,780,164, Nov. 4.

Recuperator furnace for glass tanks, etc. W. A. MORTON. Brit. 331,315, May 3, 1929.

Glass furnace heated by oil burners, etc. A. A. LAMBERTI and A. E. J. HOOPER. Brit. 331,881, March 11, 1929. Structural features.

Tunnel kilns for ceramic ware. H. M. ROBERTSON. Brit. 331,224–5, May 9, 1928. Structural features.

Applying coatings to porcelain vases or other articles. G. M. BROWN and H. T. WYSE. Brit. 331,201, Feb. 19, 1929. Various details are given of the use of floating films of coating materials which may include a pigment in a vehicle such as boiled linseed oil thinned with a volatile solvent, cellulose deriv. lacquers, printers' ink, ox-gall and water, etc., as in the manuf. of paper with marbled effects.

Refractory material. JEGOR I. BRONN. U. S. 1,780,114, Oct. 28. A highly refractory material adapted to form blocks when heated is formed by mixing Ca aluminate cement and a Cr ore such as chromite. Cf. *C. A.* **24**, 479.

Corrugated refractory bricks for lining hot blast stoves, etc. VEREINIGTE STAHLWERKE A.-G. Brit. 332,092, Aug. 9, 1929. Structural features.

Enamel ware. OSCAR HOMMEL. U. S. 1,779,273, Oct. 21. Iron or steel ware is coated with Co carbonate, the coating is transformed to Co oxide on the surface (suitably by heating) and an enamel coating is applied over the film of Co oxide. Oxides of Ni or Mn also may serve as the preliminary coating.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Portuguese standard specifications for cement. ANON. *Tonind.-Ztg.* **54**, 1319 (1930).—Similar to the German specifications. For use in contact with the sea water, specimens stored in sea water must meet the standard specification and after 84 days such storage must have 23 kg./sq. cm. tensile and 350 compressive strength. F. O. A.

A suggested method for proportioning and determining the compositions of cement slurries. TYRRELL B. SHERTZER. *Rock Products* **33**, No. 21, 70–1(1930).—The method consists of computations of chem. analyses in terms of lime equivs. R. W.

Slag cement. P. P. BUDNIKOV. *Stroitelnuie Materialui* (*Building Materials*) No. 2, 18–22(1930).—In fusing cast iron, slags are obtained which consist of double silicates of lime and alumina. When these slags are cooled suddenly hydraulic granular slags are obtained. The prepn. of hydraulic cements from slags is based on the fact that amorphous silicic acid contained in slags forms insol. hydrates of silicates and aluminates when mixed with lime and water. The lime content of slag is very important as the greater it is, the better is the cement. Slags poor in lime must have a high content of alumina to produce good slag cements. A high content of silica makes slag inert for the reaction. Ca sulfate always contained in slag changes into gypsum on hardening and is not injurious. Slag cements have a great advantage over portland cement as they are less affected by salts. Slag concrete is also less affected by salts as this concrete contains only very little uncombined lime. The resistance to pressure of portland slag cement after 28 days is 600–650 kg./sq. cm. and its resistance to breaking is about 38 and more kg./sq. cm. M. V. KONDOIDY

Slate as a raw material and fuel in cement industry. RAKOVSKII. *Stroitelnuie Materialui* (*Building Materials*) No. 4, 23–8(1930).—R. describes investigations made to det. whether Russian slates (compn. given) may be used as raw material and fuel for the prepn. of clinker. Data on the clinker obtained are given. It is noted that the solidity of this clinker is somewhat lower than the solidity required by standards for clinker. M. V. K.

Ashes absorbed by cement clinker. H. MOSCHITZ. *Tonind.-Ztg.* **54**, 1430–1 (1930).—The dust removed from a cement kiln was about 3% of the total charge of raw materials plus ash. Almost all of this dust was ash and most of it escaped from the chimney. The clinker, made from thickened slurry, takes up about 40% of the ash. F. O. A.

The chemistry of portland cement manufacture. II. Effect of sulfur and its compounds. ALTON J. BLANK. *Concrete* (*Mill Section*) **37**, 81–3, 89–90(1930); cf. *C. A.* **24**, 5962.—S in raw materials or absorbed from fuel leads to difficulty in burning and unsoundness of cement if the amt. becomes sufficiently large. R. W.

German standard specifications for portland cement, iron portland cement and blast-furnace cement. ANON. *Tonind.-Ztg.* **54**, 1292–6(1930).—The tensile strength test is given less weight than previously. Specifications for high early strength cements are 25 and 250 at 3 days with water storage and 40 and 500 at 28 days combined storage in kg./sq. cm. for tensile and compressive, resp. The 3 cements are on a par except as to definition. F. O. ANDEREGG

Methods for calculating raw pastes in the production of portland cement. I. A. ALEKSANDROV. *Stroitelnuie Materialui* (*Building Materials*) No. 1, 8–16(1930).—A discussion and review of different methods for calcg. pastes of portland cement illustrated by tables and diagrams. M. V. KONDOIDY

Influence of sand additions on the mechanical properties of portland cement. A. V. FILOSOFOV. *Stroitelnuie Materialui* (*Building Materials*) No. 1, 16–21(1930).—Tests were made to obtain a "sand cement" contg. 0–30% sand, portland cement clinker and gypsum (2% of the weight of the clinker). The chem. compn. of these materials is given and tests are described. The results are tabulated and show that addns. of up to 20% of sand to portland cement do not lower its resistance to pressure and that addns. of sand do not influence the setting time of cement. M. V. K.

Influence of clay additions on the mechanical properties of portland cement. A. V. FILOSOFOV AND F. A. SOROMITIN. *Stroitelnuie Materialui* (*Building Materials*) No. 1, 21–3(1930).—Investigations were made on portland cement with addns. of 0–30% clay. Data on the fat brick-clay used and clinker with an addn. of 4% gypsum are given and tests described. The results are given in tables and showed that the setting time is not influenced by the quantity of clay although pastes with clay set quicker than pure cement contg. 4% gypsum. The mech. solidity of cements is lowered

in proportion to the clay content, but on the other hand, the density of cement is increased. Unfired clay cannot be used as addn. to portland cement. M. V. K.

Dusting of portland cement clinker. KATSUZO KOYANAGI. *Rock Products* **33**, No. 24, 66–8(1930).—Dusting of clinker takes place in segregated portions rich in $2CaO.SiO_2$. RAYMOND WILSON

Chemical characteristics of cement pipe lining. E. L. CHAPPELL. *Ind. Eng. Chem.* **22**, 1203–6(1930).—The protection of iron water pipes by linings of cement depends upon alky. of the lime in the cement next the iron wall and upon the blanketing effect of the cement layer. Protective layers made of northern natural cements in contact with city water for some 50 years were found to have lost all lime, which had been replaced by Fe hydroxide to give complete protection. The corrosion rate of Fe can be reduced by covering with a layer of silica sand which becomes cemented together by the Fe hydroxide. This protective effect varies with the thickness of the silica layer. Lime leaching out increases the hardness of the water and so a cement has been developed high in Fe and silica and low in lime for this special purpose. F. O. A.

Analyses of complicated concrete mixes. J. L. HEITZMAN. *Rock Products* **33**, No. 23, 62–4(1930).—Methods for the analyses of cinder, slag and other portland cement concretes are described. RAYMOND WILSON

Shrinkage and expansion of concrete while hardening. P. FILOSOFOV AND A. M. SHCHEPETOV. *Stroitelnuie Materialui* (*Building Materials*) No. **2**, 22–9(1930).—The authors review tests made to det. the shrinkage and expansion of concrete while hardening and describe their own tests which showed that: (1) The properties of the cement, sand and aggregates used are of great importance for the shrinkage of concrete; quick setting cements and cement of high qualities have a greater shrinkage. (2) The fatter is the concrete the greater is the shrinkage. (3) A damp environment weakens the phenomenon of change of vol. of concrete during hardening. M. V. KONDOIDY

Waterproofing of concrete structures. H. R. LORDLY. *Trans. Soc. Eng.* (London) **1929**, 55–93.—Tarry solns. should be applied to the surface when warm. A processed artificial gypsum acting as a carrier for tannin is added to portland cement to make it waterproof. It also acts as a catalytic agent to promote hydration of the silicates and aluminates. Mixts. are given for cement laid under water, used to stop leaks from the inside, and repairing underwater damage to ships. ANN NICHOLSON HIRD

Trass of Karadag. C. SHCHUKIN. *Stroitelnuie Materialui* (*Building Materials*) No. **2**, 29–35(1930).—The deposits of trass in U. S. S. R. are found only in Crimea. It is a volcanic tufa contg. the so-called "active silicic acid" which gives trass its hydraulic properties. The results of the chem. analyses of trass are tabulated and compared to German and Italian trass. They showed that the green Russian trass contg. 71% silicic acid is especially appropriate for use in cements. Tests made with such cements showed that after hardening 3 years, the solidity of trass cements was much greater than that of portland cement and it continued to increase. The most valuable property of trass is that it prevents the injurious action of sea water on concrete by the action of its "active silicic acid" which absorbs the surplus lime and forms cryst. silicates of Ca insol. in water. The compn. of Russian trass portland cement and its properties are tabulated.

M. V. KONDOIDY

Emulsifying action of asphalt fillers. A. R. EBBERTS. *Rock Products* **33**, No. 24, 53–5(1930).—Silica, Fe oxide and gypsum promote the formation of asphalt in water emulsions. Limestone, $MgCO_3$, $Ca(OH)_2$, $Mg(OH)_2$ and portland cement promote the formation of water in asphalt emulsions. The latter class of fillers is best suited for paving mixts. RAYMOND WILSON

Use of the filtration method in volumetric analysis, particularly in the analysis of portland cement (BUCHERER, MEIER) **7**. Basic slags from blast furnaces and their utilization for manufacturing cement (BUDNIKOV, LEZHOEV) **9**. Study of colonial wood from Spanish Guiana (BATUECAS) **21**. Uniform description of graded materials and the evaluation of their fineness (SPINDEL) **13**. Colloidal nature and water content of clays (BERRIDGE) **2**.

Cement. J. C. G. SPERNI. Brit. 332,282, April 18, 1929. A magnesian cement (such as one produced by finely powdering together burnt magnesite and dry unburnt clay or by burning magnesite and clay together) is mixed with 5–25% by volume of Mn oxide, to produce a hard-setting cement. Fillers such as sand, sawdust, "fiber," cork, leather waste or pigments may be added.

Portland cement. FREDERICK W. HUBER. U. S. 1,781,232, Nov. 11. A raw material such as phosphatic marl, which contains Ca phosphate in substantial amounts

and in which the mineralizing components are in too small quantity to produce good cement by burning with argillaceous material at the usual cement burning temp. followed by pulverizing, is mixed with argillaceous material and with an Fe oxide material to bring the total Fe content up to above the chem. equiv. of the phosphate radical present, and the mixt. is burned at a temp. which will convert all the phosphate into Fe phosphate, leaving an excess of Fe oxide, and the product is ground to a fine powder.

Portland cement. F. S. WATT. Brit. 332,322, May 7, 1929. A fine spray of slurry is caused to pass through the hottest part of the flame in a kiln to produce a clinker in a fine state of subdivision. App. and various details of operation are described.

Portland cement. BRITISH PORTLAND CEMENT MANUFACTURERS, LTD., S. G. S. PANISSET and W. S. HANNAH. Brit. 331,584, April 6, 1929. In order to produce a white cement, the raw materials, immediately after the calcining process, are treated with a reducing agent (such as coal dust or paraffin oil spread on a surface onto which the hot clinker is allowed to fall), followed by immediate cooling to prevent reoxidation.

Cement for cementing off oil wells, etc. RICHARD BUHMAN. U. S. 1,781,267, Nov. 11. A usual cement mix is treated with $CaCl_2$ to serve as a dehydrating agent and with $FeCl_3$ which will react with the cement to form addnl. $CaCl_2$ and a hydroxide which acts as an initial set-retarding agent.

Rotary kiln suitable for burning cement. ROBERT W. P. HORN and JACOB H. NISSLEY. U. S. 1,779,626, Oct. 28.

Porous concretes. MOSLER SAFE CO. Brit. 332,356, June 11, 1929. A heat insulation suitable for use in safe linings is prepd. by mixing a vermiculite material such as jeffersite, kerrite or maconite (which preferably has been heated to open out the scales) with a binder such as portland cement or plaster of Paris, with or without addn. of diatomaceous earth or a similar material.

Waterproofing and permitting hydrolysis in concrete. GEORGE C. MARTIN. U. S. 1,779,481, Oct. 28. Neat concrete is poured and while still wet there is applied to its surface asphalt heated sufficiently to cause steam in the concrete to promote quicker soln. of the retarding substances in the cement of the concrete.

Bituminous concrete pavement. DONALD M. HEPBURN (to Amiesite Asphalt Co. of America). U. S. 1,779,067, Oct. 21. Mineral aggregate comprising clean, graded broken stone is coated by agitating it with a bituminous cement in fluent mobile condition and in excess of the quantity which would remain on the aggregate if it were not for the agitation, and, while continuing the agitation, clean sandy fines are added insufficient appreciably to reduce the voids in the finished pavement but sufficient to prevent running off of the fluent bituminous cement on cessation of the agitation, thus producing a loose material suitable for transporting and subsequently compacting on a roadway. Cf. *C. A.* **24**, 706, 3341.

Surfacing roads with concrete and bituminous material. S. J. L. ROBINSON and J. C. MANN. Brit. 332,388, July 6, 1929. Small fragments of pitch, bitumen, asphalt or the like are distributed in an open mosaic fashion over the surface of concrete before setting, and are tamped or rolled flush with the concrete. The bituminous material may be mixed with screened cement applied for finishing if desired.

Asphalt paving composition. JAMES S. DOWNARD. U. S. 1,781,105, Nov. 11. A cooled granulated mixt. of asphalt and sand is treated with a $CaCl_2$ soln. in order to prevent adhesion of the granulated mixt. during storage or transportation and the material is subsequently rendered adhesive by treatment with NH_4 oxalate before application to a roadway.

Paving material. ERNEST A. YOUNG and GLENN H. ALVEY (to Uvalde Rock Asphalt Co.). U. S. 1,779,954, Oct. 28. A mass of crushed rock asphalt of graded sizes proportioned to give a minimum of voids is treated with a flux, and there is added to the mixt. a crushed rock which is harder than the rock asphalt and is of sizes and quantity to create voids in the total mixt. U. S. 1,779,955 (ERNEST A. YOUNG) describes a method of laying a pavement comprising spreading a loose layer of crushed asphalt rock, sized and proportioned to give a balanced mixt. with a minimum of voids, spreading over this layer a scattered layer of crushed stone harder than the first layer and comprising a one-sized aggregate substantially the size of the coarser rock asphalt aggregate, the layers being then compacted together. Cf. *C. A.* **24**, 4373.

Blocks and walls of x-ray-proof material. DAVID H. BARRY. U. S. 1,780,107–8, Oct. 28. Structural features.

Laminated wall board. PHILIP W. CODWISE (to Certain-teed Products Corp.). U. S. 1,780,743, Nov. 4. A pulp is formed by beating with water a mixt. of paper waste about 35%, wood flour 35% and ground wood 30%; the pulp is formed into plies.

several plies are compressed between plies of sized wood-pulp screenings and sawdust to form a coherent layer with rough surfaces and a thickness of about 0.08 in. and several layers thus formed are cemented together to form a rigid board suitable for use as a plaster-base board.

Sheet material for panelling, etc. D. SINCLAIR. Brit. 331,573, April 2, 1929. Sheet material such as "Celotex" formed by pressing or rolling bagasse or similar fibrous material is impregnated with shellac or artificial resin varnish, compressed to expel excess liquid and baked under pressure (suitably at about 200° for 45–60 min.). Material for elec. shielding may be similarly formed with interposition of Cu gauze or other suitable cond. material between two sheets of the impregnated board. Various details and modifications of manuf. are described.

Laminated soundproof, fireproof and waterproof sheet material. R. ARNOT. Brit. 331,561, Feb. 4, 1929. One or more layers of balsa wood or other suitable fibrous material are provided with outer coverings such as thinner asbestos sheets, cement, metal, parchmentized fireproofed fiber or canvas and synthetic resins, sol. silicate or portland cement may be used in uniting the materials.

Asphalt-impregnated roofing. LOWELL F. LINDLEY. U. S. 1,779,175, Oct. 21. A heavy felt is impregnated with an asphaltic waterproof compn. stiff at summer sun temp., the impregnated felt is coated with a layer of adhesive asphalt, grit is embedded in the coating and the sheet is corrugated lengthwise into arcuate corrugations and is cut transversely. App. is described.

Apparatus for saturating sheet material such as roofing felt with asphalt, etc. HILDING A. SJODAHL (to Patent and Licensing Corp.). U. S. 1,778,733, Oct. 21. Structural features.

Veneering lumber with a film of heat-curable material such as bakelite. LOUIS T. FREDERICK (to Continental Diamond Fibre Co.). U. S. 1,779,426, Oct. 28. A film of an adhesive such as glue is interlaid between a surface such as lumber and a roughened veneer sheet such as laminated paper and bakelite with a cured surface, and the materials are united under pressure.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The inorganic constituents of fuel and their importance for modern furnace technic. W. REERINK AND K. BAUM. *Die Wärme* **53**, 746–51, 766–71(1930); cf. *C. A.* **23**, 5301.—Recent expts. concerning the inorg. constituents of fuel ash indicate a clear distinction between coal ash and lignite ash with regard to their compn. and fusion characteristics. The detn. of the m. p. of both types of ash by the use of Seger cones yields unreliable results. The method of Bunte and Baum (*C. A.* **22**, 1457) offers in contrast the possibility of obtaining fusion curves which are reproducible and which allow the initial softening and course of the fusion process to be distinguished clearly. It is important that the ash for testing be prepd. in a uniform manner. The ashing temp. should not exceed 800° for coal and 700° for lignite. The atm. should be strongly oxidizing and the combustible content should be reduced to less than 0.5%. As the result of several hundred tests, it is shown that essentially 3 different types of fusion curves appear. The effect of Fe oxide in the ash is discussed. It is shown that with the conditions of the mixed atm., a low-melting ferrosilicate, fayalite, is formed. The principal cause of ash fusion at low temps. must be regarded as the Fe oxide content which, if it amounts to more than 15–20% and if a corresponding amt. of free silica is present, is responsible for slag formation in the conditions of the mixed atm. An ash of higher Fe oxide content but low silica may not melt at a low temp. (below 1200°). Further expts. indicate the influence of alkali and alkali earth salts on the fusion process of lignite ash. The question of grate-bar attack is briefly considered. The relationships between type of furnace and ash and between the type of coal and its ash is as yet largely unexplained.

ALLEN S. SMITH

Determination of the calorific value of solid substances. W. A. ROTH. *Brennstoff-Chem.* **11**, 46–7(1930).—Paraffin oil is suggested as a secondary standard in detg. the water equiv. in calorimetric measurements. If it is added to substances difficult to ignite or to use in pellet form, combustion is easily effected. It is also of value in inorg. oxidations and reductions in calorimeter bombs. Volatile substances are sealed in glass capsules and covered with paraffin oil. The paraffin oil for calorimetric purposes is obtainable from Schering-Kahlbaum A.-G. Berlin with a heating value of 10,990 ± 2 cal./g.

F. W. JUNG

Refining of benzene. Action of chlorine on crude benzene. T. RABEK. *Brennstoff-Chem.* **11**, 189–92(1930); cf. *C. A.* **24**, 4923.—For satisfactory motor-fuel uses, it is not necessary to remove all constituents barred by the H_2SO_4 test and Br no. from light-oil fractions of coal-tar and scrubbings of coal gas. Discoloration in the H_2SO_4 test is shown to be also due to constituents other than unsatd. compds., *e. g.*, S compds. of the thiophene type and showing the isatin reaction. It was not proved that resin-forming constituents which lower the heat value also give the test. The Br no. actually gives unsatd. compds. When the benzene is treated with Cl, the unsatd. constituents are attacked first and then the S compds., while the benzene itself remains unchanged. The distribution of unsatd. compds. is shown graphically with distn. and chlorination data. The absence of unsatd. compds. and impurities in intermediate fractions suggests refinement by simple fractionation. F. W. JUNG

The hydrogenation of fuels. M. G. LEVI, C. PADOVANI AND A. MARIOTTI. *Ann. chim. applicata* **20**, 361–404(1930).—An outline is given of the Bergius process for hydrogenating liquid and solid fuels. Several expts. in hydrogenating Italian fuels by this method are described. The authors find that Fe_2O_3 and Ni_2O_3 catalyze the reaction, but note that Bergius discards the use of catalysts. A. W. CONTIERI

Plassmann process of low-temperature carbonization. D. BROWNLIE. *Brennstoff-Chem.* **11**, 44–6(1930); cf. *C. A.* **24**, 4376.—The Plassmann-C. T. G. plant under construction at Barking near London is described. Three units of the type at the Prosper plant but with revolving parts interchanged are each to give a daily throughput of 65–67 tons of washed coking coal of 25–35% volatile content and 5–6% ash. This is to be carbonized at 500–600° in 4.5–6 hrs., giving 26–3400 cu. ft. gas per ton, 40% of which is to be used in heating, and a dust-free tar. Anthracite fines washed by the Lessing process to 1.5% ash may be added up to 25%. "Colconite" of 7.5% ash is to be sold unsized as a smokeless domestic fuel. F. W. JUNG

Low-temperature carbonization [of coal] in thin layers. H. MANTEL. *Brennstoff-Chem.* **11**, 150–1(1930); cf. *C. A.* **23**, 4329.—The app. of Brit. pat. 301,907 (*C. A.* **23**, 4329) is described with diagram. A large throughput of pulverized or fine coal or lignite is carbonized in 1–2 mm. layers at 350–80° by rapid heat transfer from a rotating annular hearth plate heated from below. A dust-free and undiluted gas and an uncracked truly low-temp. tar are produced. F. W. JUNG

Analyses of coals and other solid fuels. J. H. H. NICOLLS AND C. B. MOHR. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 36–56(1930).—Analyses of 181 samples of solid fuel are given. ALDEN H. EMERY

Observations concerning organic and other forms of sulfur in coals containing large amounts of sulfur. J. H. H. NICOLLS AND E. SWARTZMAN. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 28–35(1930).—Extn. of coal with 3% HCl or H_2O shows: (1) oxidation of pyritic S to form sulfates of Fe takes place in regular increments in successive treatment; (2) aq. extn. promotes more oxidation than HCl; (3) CO_2 over the extn. retards oxidation; (4) temp. increase retards oxidation; (5) inorg. sulfide S is evolved from certain coal samples following addn. of HCl; (6) dil. HNO_3 may dissolve a little org. S; (7) S described as "pyritic" is better described as "sulphide"; (8) coal will not promote reduction and so inhibit the oxidation of pyrite; (9) variations of the usual method for detg. sulfate brought distinct changes, none of particular magnitude. Digestion with HNO_3 (sp. gr. 1.12) showed (1) org. S is often lost during digestion so the most suitable method for its estn. is by subtraction of inorg. S from total S; (2) the originally proposed method for detg. humus S is probably unreliable. A. H. E.

Distribution of sulfur in the combustion of coal and coke. I. TRIFONOV AND E. RASHEVA-TRIFONOVA. *Brennstoff-Chem.* **11**, 165–9(1930).—Analytical data are presented showing the distribution of S in various inorg. compds. in coal and coke before and after combustion. The inorg. S-free coal and coke used were prepd. from a Bulgarian coal which was pulverized, washed by a flotation treatment with a CCl_4-xylene mixt. of sp. gr. 1.30 and shaken with HNO_3 of sp. gr. 1.20. The effects of combustion at different temps. upon various ash constituents, inorg. S compds. and combinations of these in 10 and 15% mixt. with the coal and coke are given. F. W. JUNG

Effect of addition of dolomite on carbonization and combustion of coal (sulfur distribution). I. TRIFONOV AND E. RASHEVA-TRIFONOVA. *Brennstoff-Chem.* **11**, 185–8 (1930); cf. preceding abstr.—By means of 10% mixts. of dolomite with representative coals, S distribution before and after carbonization and degasification, at 900° in a Krupp-steel retort, and combustion have been further studied. No specific influence upon carbonization yields was found but the difference noted in distribution was greater than that obtained with equiv. mixts. of dolomite constituents. The retention of S by the ash is attributed to a protection by $CaCO_3$ upon $MgSO_4$ formed, $MgCO_3$ alone not

retaining S on combustion. In slow coking, $MgCO_3$ retained less S than did $CaCO_3$, the reverse being true in rapid coking; this is explained by the greater alky. of $CaCO_3$ in reaction with H_2S. In many instances, the coke was strengthened by the dolomite addn.; this was attributed to cementation. The S content of ash was the same whether produced by coking followed by ashing or by direct ashing. F. W. JUNG

Iodine content of coal. E. WILKE-DÖRFURT AND H. RÖMERSPERGER. *Z. anorg. allgem. Chem.* **186**, 159–64(1930).—Ignition of a mixt. of powd. coal and K_2CO_3 results in loss of I_2 by volatilization. Good results are obtained by heating 30 g. of finely powd. coal with 1.5 g. of K_2CO_3 and 400 cc. of 50% alc. for 8 hrs. at 270–80° in an autoclave, whereby all the I_2 is rendered sol. The soln. is filtered and evapd. to dryness, the residue heated gently to carbonize org. matter and extd. with water, and the C sepd. by filtration; this procedure is repeated until a colorless filtrate is obtained in which the I_2 is detd. volumetrically by Winkler's method (*C. A.* **11**, 3070). The I_2 contents of 12 mid-European coals were found to vary from 0.85 to 11.17 mg. per kg., but no relation could be established between the age of a coal and its content of I_2. It is calcd. that, based on a consumption of 1200 million tons of coal per annum, about 7 million kg. of I_2 is returned to circulation on the earth's surface. B. C. A.

Heat evolved on the treatment of different varieties of coal with concentrated sulfuric acid or nitric acid. D. J. W. KREULEN. *Brennstoff-Chem.* **11**, 41–3(1930).—The Burstin-Winkler type of calorimeter was used to det. the heats of oxidation of various coals, coal constituents and forms of C, 0.5 g. of 50-mesh dry coal being treated with 10 cc. of 95% H_2SO_4 or 50% HNO_3 and the results were calcd. ash-free. With HNO_3, values increased 30–130 cal./g. with increase in volatile content of the coal but with H_2SO_4 results were less uniform perhaps because of oxidation of substances other than volatile constituents. Preheating the coal to 125–150° increased the heat of oxidation but preheating to 175° decreased it. The heats of oxidation of vitrain and clarain were the highest of the banded constituents; durain was next, while those of fusain were very small and similar to those obtained with wood charcoal. F. W. JUNG

Effects of prolonged weathering on the friabilities of certain coals. J. H. H. NICOLLS AND E. SWARTZMAN. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 27–8 (1930).—Samples of 4 Alberta domestic coals and 1 Scotch semianthracite were exposed for 3 years. None underwent any great disintegration The first year showed most change. ALDEN H. EMERY

A comparison of pulverized coal and stokers in industrial plants. SAMUEL M. GREEN. *Power* **72**, 722–5(1930). Installation costs and manufacturer's performance guarantees are compared. D. B. DILL

Production of fuels from brown and waste bituminous coals in the Lurgi plant. O. HUBMANN. *Brennstoff-Chem.* **11**, 219–22(1930).- The American and Canadian Lurgi plants with improved carbonizing units capable of 200 tons per day uninterrupted throughput at temps. increased from 800° to 900° are described. By use of small coal from which fines have been screened for boiler fuel a coke of lower ash is obtained The tar which has been reduced in free C to 0.5% yields an oil rich in phenols and 30–50% pitch which can be increased by oxidation of the tar. Reenforced when needed with coal-tar or asphalt pitches, the hot atomized pitch is used in briquetting the pulverized coke, the amt. necessary having been decreased from 9–10% to 6.5–7.5%. The rectangular briquet has been found easier to make than the egg-shaped and possesses many advantages as a domestic fuel. Because of the method of carbonizing in a vertical stack by direct contact with the heating gases which contain SO_2 formed from the H_2S in the coal gas, the S content of the coke is 2% but this is 70% non-combustible. The larger sizes may be sold directly as fuel. Coke analyses for various carbonizing temps. and a schematic diagram of the process are given. F. W. JUNG

Distribution of carbon, hydrogen, nitrogen, sulfur and oxygen in the hydrogenation products of an eocene brown coal. I. VON MAKRAY. *Brennstoff-Chem.* **11**, 61–4(1930).—Analytical data for original materials and resulting gas, oil, liquor and residue are given showing the distribution of these elements in combinations in the hydrogenation of coal ' in presence of Fe_2O_3. Distribution is also shown diagrammatically. F. W. JUNG

Brown coal as a raw material for gas production. W. HAUSWALD. *Brennstoff-Chem.* **11**, 151–2, 172–4(1930).—The practicability of domestic gas production from brown coal by various methods is examd. The use of existing, *e. g.*, vertical, high-temp. ovens involves actions of alk. ash on retort walls, flash-back tendencies of coke on discharging and the expensive cracking of the tar over the briquetted coke to raise the gas B. t. u. Low-temp. methods mean the subsequent cracking of the gas over the coke,

giving a gas too high in sp. gr. and CO for safety. Satisfactory gas production is possible in generators of suitable design. F. W. JUNG

Acids of montan wax. II. D. HOLDE, W. BLEYBERG AND H. VOHRER. *Brennstoff-Chem.* **11**, 128–32, 146–8(1930); cf. *C. A.* **23**, 5561.—The fatty acids previously sepd. and believed to be iso-acids of octocosoic acid have been subjected to further purification, by repeated recrystns. from benzine, acetone and chloroform, and by fractional micro distn. under 0.04–0.2 mm. Hg pressure. The m. p. after correction agrees closely with that for octocosoic acid ($C_{28}H_{56}O_2$, m. 89°); this is confirmed by the x-ray analysis. From the mother liquor of the montan acid crystns. hexacosoic acid (m. 85.9°) was isolated; this, while not agreeing in m. p. with synthetic hexacosoic acid ($C_{26}H_{52}O_2$, m. 88.2°), was identified by a mixed-m.-p. detn. Behenic ($C_{22}H_{44}O_2$) and tetracosoic ($C_{24}H_{48}O_2$) acids were also believed to be present. The acids derived from montan wax are all believed to contain an even no. of C atoms and normal C cha ns; the penta-, hepta- and nonacosoic acids are concluded to be equimol. mixts. of these. This agrees with previous observations with peanut oil, beeswax, etc. F. W. JUNG

Naphthalene removal by means of tetralin. ZUMBUSCH. *Gas u. Wasserfach* **73**, 977–8(1930). - A discussion of the phys. laws underlying naphthalene removal from gas distribution systems by means of tetralin. Statements made by Weissenberger (*C. A.* **24**, 5464) are qualified to read: (1) For quick removal of old naphthalene deposits the quantity of tetralin used should be increased in summer. (2) For avoiding the formation of new naphthalene deposits the tetralin installation should be operated in winter, but may be shut down during the summer, after old deposits are removed. R. W. R.

Saskatchewan lignite. J. P. DE WET. *Canadian Mining J.* **51**, 1012–4(1930).—A new mining plant at Estevan gives a cheap clean fuel for Saskatchewan and Manitoba. W. H. BOYNTON

Under-water storage of Saskatchewan lignite. J. H. H. NICOLLS AND E. SWARTZMAN. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 25–6(1930).—Lab. tests of various exposures of lignite and anthracite are given. As long as the lignite was under water it was apparently unchanged. On exposure to the atm. it behaved like a fresh sample and rapidly checked. Analyses show little change. ALDEN H. EMERY

Report of preliminary carbonization and briquetting tests on lignite from northern Ontario. R. A. STRONG. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 7–12(1930).—Lignite analyzing moisture 39.9, ash 7.3, volatile matter 26.8, fixed C 26.0 and S 3.0% with a heating value of 6170 B. t. u. (10,265 on dry basis) was carbonized at 600°. The char yield was 37% and analyzed ash 16.5, volatile matter 7 4, fixed C 76.1, S 4.2% and heating value 12,860 B. t. u. The gas yield was 3430 cu. ft. per ton; it had a density of 0 91 and a heating value of 444 B. t. u per cu. ft. The tar yield was 5.5 gals. per ton, sp. gr. 1.065 1.3 lb. $(NH_4)_2SO_4$ per ton was also obtained. Tar analyzed as follows: 0–225°, 40.5%, 1.015 sp gr.; 225–255°, 28.4%, 1.033 sp. gr.; pitch, 27.7% Fraction I analyzed: phenols 74.0, bases 1.3, neutral oil 24.7, unsatd. substances 44.0%. Fraction II analyzed: phenols 63.0, bases 0.0, neutral oil 37.0 and unsatd. substances 33.0%. Gas analyzed: CO_2 35.3, illuminants 0.5, CO 11.6, CH_4 32.0, H_2 14.4 and N_2 6.2%. Briquets made with 9% asphalt stood handling well. A. H. E.

A new proposal for the determination of moisture in peat burned under the steam boiler. A. P. KOSMIN. *Die Wärme* **53**, 775–7(1930).—A method for detg. the moisture in peat by analysis of the gaseous combustion products is theoretically treated. The practical importance of this method can only be proven through direct expt. ALLEN S. SMITH

Lignins of some peat-forming plants of a sphagnum peat. II. G. STADNIKOV AND A. BARISHEVA. *Brennstoff-Chem.* **11**, 169–71(1930); cf. *C. A.* **24**, 5463.—The compn. of lignins isolated from sphagnum mosses and cotton grass, *Eriophorum vaginatum*, is compared with that from depths of 0.5–2.0 m. from a peat bog. That obtained at 1.5 m., supposedly pure sphagnum peat, has a greater C content because of the action of coal-formation processes. Structural formulas of similarity have been detd. for the lignins of cotton grass and peat from 1.5 and 2.0 m. depths. Sphagnum lignins are transformed into humic acids more rapidly than that of cotton grass because of their greater reactivity as shown by their behavior in water. The resistance of wood and cotton grass lignins is due to the colloidal nature rather than to antiseptic action of resins, the C_6H_6-alc. extn. of *Sphagnum parvifolium* being greater than that of *E. vaginatum*. The theory of the transformation of wood substances in coal fossils is strengthened by data showing loss of $-OCH_3$ groups with increasing bog depth and peat age. F. W. J.

Study of colonial wood from Spanish Guiana. T. BATUECAS. *Anales soc. españ. fis. quim.* **28**, 944–58(1930).—Moisture, ash, elementary analysis, heating value and apparent d. of *Aucoumea klaineana* (okume), *Risophora mangle* (mangle), *Lophira*

procera (palo de hierro), *Saccoglottis gabonensis* (osuga), *Disthemonanthus benthanianus* (oguemina) and *Musanga smithii* (palomero or parassolier) were detd. C. and H were detd. by the H. ter Meulen and J. Heslinga method. Apparent d. was detd. by a volumeter (*Physikalisch-chemische Praktikumaufgaben*, 1928), slightly modified. Detns. on *Eucalyptus globulus* are included. E. M. SYMMES

Formation of methane from carbon monoxide and hydrogen by bacteria. R. LIESKE AND E. HOFMANN. *Brennstoff-Chem.* **11**, 208–12(1930).—Sludge of sewage, ditches and stagnant water contains long, Gram-positive, non-spore forming, sometimes incompletely stained, bacilli without cilia of the lactic acid type which bring about the reaction, $CO + 3H_2 \longrightarrow CH_4 + H_2O$ and which are believed to be those of Söhngen (*C. A.* **4**, 2954). The CO and H of pure gas mixts., illuminating gas and fuel gas have been converted to CH_4 in closed vessels at temps. of 16–33° with yields of as high as 97% in 2–3 weeks. Sludge or a colloidal medium is needed in the process which also produces some N and removes the O in the gas as H_2O. No nutriment is necessary when org. matter is present in the sludge. Passing the gas over the cultures in a continuous stream trebled the CO content instead. F. W. JUNG

(Gas) generator supervision. F. KRETZSCHMER AND J. MÖLLER. *Die Wärme* **53**, 763–5, 784–7(1930).—Generator resistance, charge resistance, steam flow, gas temp., gas pressure and gas analysis are discussed and explained with reference to the importance in gas generator operation. The principles of the measurement of the quantities are given. ALLEN S. SMITH

Natural gas in Saskatchewan. G. S. HUME. *Can. Mining J.* **51**, 991–4(1930).—Four conditions considered necessary for the presence of natural gas in com. quantities are: (1) presence of a source rock that might yield natural gas; (2) presence of suitable porous rocks in the strata assocd. with the source beds; (3) presence of a suitable geological structure to cause the accumulation of natural gas in local concns. such as would yield com. supplies when the gas-bearing horizon is encountered by the drill; and (4) presence of a suitable cover over the natural gas-bearing horizon to prevent the escape of the gas after concn. Dirt Hills, south of Moose Jaw, and an extension of the Ribstone area into Saskatchewan are regarded as a favorable area. W. H BOYNTON

The Munich method for determining heat distribution inside a gas oven. HERMANN KOELSCH. *Gas u. Wasserfach* **73**, 998–9(1930).—Drawing paper coated by brushing with a soln. of 120 g. $Na_2CO_3.10H_2O$ per l. of distd. water and dried under tension may be used to indicate the temp. variation in gas-heated (baking) ovens, at temps. between 140 and 250°. Before using the paper is fastened in a frame. Details of the test are given. Other heat-sensitive materials were tested but the above was found to give the best results. R. W. RYAN

The new horizontal (small) chamber oven plant at Waren (Müritz). G. O. EICHNER. *Gas u. Wasserfach* **73**, 950–2(1930).—Details are given of the new gas plant at Waren, which uses 6 small vertical chamber ovens, of the Pintsch and Otto type, 3500 mm. long, 1000 mm. high and with an av. width of 300 mm. The charge is 650 kg. and the coking time 12 hrs. R. W. RYAN

Physical basis and method of operation of the Progas-Union (gas) governor of 1929. E. FREI AND C. BARCKMANN. *Gas u. Wasserfach* **73**, 967–73(1930).—The design and phys. basis of the Progas-Union governor are discussed with a mathematical analysis. Curves are given which show the gas-pressure variations before and after the governor. R. W. RYAN

Temperature control in exothermic gas reactions. O. ROELEN. *Brennstoff-Chem.* **11**, 68–70(1930).—A discussion. F. W. JUNG

Chemical reactions in the Petit process (of gas purification). W. TER-NEDDEN. *Brennstoff-Chem.* **11**, 67–8(1930).—A description is given of the operation, with equations and equilibrium data, to explain the reactions occurring in the various stages of the process whereby K_2CO_3, H_2S being removed from the gas as KSH, is satd. with CO_2 to expel H_2S, the resulting $KHCO_3$ being decompd. with heat to the original K_2CO_3. A flow-diagram is given. F. W. JUNG

Preventing the harmful action of gases and waste waters containing phenols in the operation of gas producers. FELDHAHN. *Zentr. Gewerbehyg. Unfallverh.* **17**, 122–3 (1930); *Chimie & industrie* **24**, 587.—In the heating of large furnaces (for metallurgy, ceramics, etc.) with purified lignite producer gas, the tar must be removed from the gases and then cooled in a scrubber with a counter-current of water. The scrubber waters contg. phenols are generally cooled in a reflux condenser by being finely subdivided in direct contact with the air. This results in harmful action when the waters are discharged into water courses, and moreover their odor is disagreeable to the neighborhood. To overcome these drawbacks, F. suggests that the waters from the scrubber

be cooled in tubular coolers and then returned to the scrubber for the purification of the gas, while the tubular coolers are surrounded by fresh water which is passed through a reflux condenser. The scrubbing and cooling waters are thus kept entirely sep., which prevents the escape of bad odors as the waters contg. phenols are no longer cooled in the reflux condenser; moreover, they cannot contaminate the cooling water and can be withdrawn from the cycle when the phenol content has reached a given point.

A. PAPINEAU-COUTURE

Position of activated carbon process for benzene recovery from coke-oven and illuminating gas. E. REISEMANN. *Brennstoff-Chem.* **11**, 226–9(1930); cf. *C. A.* **15**, 1031, 2540.—Details and a schematic diagram of the Bayer process are given with exptl. data of a recent English installation. The outlook for this method of recovery is discussed.

F. W. JUNG

Removal of sulfur dioxide from flue gases. A. THAU. *Brennstoff-Chem.* **11**, 222–6(1930).—The necessity and various methods of combustion- and flue-gas analysis are discussed. An exptl. app. working with the gases of a Northumberland (3.9% S) and a Scottish (1.23% S) coal, the S content of whose gases varied from 1 to 5 mg. per cu. m. expressed as H_2SO_4, is described. The treatment completely removed SO_2 and SO_3 with a H_2O scrubbing of 12–14 sec. contact duration corresponding to H_2O requirement of 45–58 tons per ton coal. With hot water, oxidation of SO_2 to SO_3 takes place and the wash water does not later give off SO_3. Neutralization methods using lime, because of cost and dust, were not studied. Ests. of SO_2 production at the Battersea power station near London are given together with diagrams of suggested scrubbers.

F. W. JUNG

Use of coal-tar oil for heating industrial furnaces. H. LUHN. *Brennstoff-Chem.* **11**, 192–3(1930).—A discussion and answer of objections against substitution for other fuel oils. Analytical, combustion and cost comparisons are made in favor of coal-tar oil as used in the latest installations employing preheating of both fuel and atomizing air.

F. W. JUNG

Nature of the coking process. F. FISCHER. *Brennstoff-Chem.* **11**, 64–6(1930).—A description and discussion of the effects upon the coking of coal by humic substances and solid and oily bitumens. Primary (decompn. of bitumen) and secondary (coking of tar) carbonization are defined. The comparative effect upon coke structure using hot-oven charging and the reheating to 1100° of semi-coke as well as the coking of non-caking coals under pressure to overcome the effect of insufficient oily bitumen are also discussed.

F. W. JUNG

Heat economy of coke ovens. K. BAUM. *Brennstoff-Chem.* **11**, 47–51(1930).—The heating efficiency of coke ovens obtained by both the detn. of heat losses and sectional heat concns. is discussed together with the influence of end temp., heating rate, coal moisture content, etc., upon the heat of carbonization. The heat of carbonization for an oven, while useful, should not be taken as an absolute index of heating efficiency. Improvements in design and operation technic are recommended to increase the heating efficiency. Isothermal diagrams are given showing variations in the progression of heating in various sections of the charge and differences in end temp. in 2 types of ovens.

F. W. JUNG

Heat economy of coke ovens. O. PEISCHER. *Brennstoff-Chem.* **11**, 112–13 (1930).—The factors detg. heat efficiency and economy in coal carbonization as given by Baum, (cf. preceding abstr.) are discussed. In regard to uniformity of heating, to prevent undue cracking of gas and tar and decompn. of NH_3 in upper section of oven, a vertical temp. gradient is desirable. Quality of the product should also be considered. Reply. K. BAUM. *Ibid* 113–14.

F. W. JUNG

Determination of the reducing power [of coke, etc.] by Agde and Schmitt's method. W. J. MÜLLER AND W. COURARD. *Brennstoff-Chem.* **11**, 125–8(1930).—Improvements and refinements in app. and procedure, such as a const.-head device for uniformity of CO_2 flow, a combustion tube designed to reduce dead spaces and permit truer temp. control, and a more accurate analytical buret system are described. Curves for various cokes, wood- and activated-charcoals are given showing reducing power and residual gas vols. for different particle sizes.

F. W. JUNG

Beet sugar molasses prices and molasses utilization [as power fuel] (CLAASSEN) **28.** Progress report on waste sulfite liquor (HOWARD) **23.** Refining light oil from coal distillation (U. S. pat. 1,779,944) **22.** Activated ferric oxide (Brit. pat. 332,259) **18.** Plastic coating materials from tars, etc. (Brit. pat. 331,846) **26.** Separating waxy materials from distillates, etc. (U. S. pat. 1,779,287) **22.** Apparatus for demulsifying oils and tars containing water by heat, baffling and gravity (U. S. pat. 1,781,257) **22.**

Fuel briquets. HENRY F. MAUREL (to Maurel Investment Corp.). U. S. 1,780,205, Nov. 4. Fuel suitable for use in furnaces is prepd. by subjecting carbonaceous materials such as pulverized coal to froth-flotation concn., reducing the moisture in the concentrates to form a heavy paste, mixing the latter with a suitable liquid hydrocarbon material such as a heavy asphalt base oil and finally baking the mixt.

Mixed liquid or semi-solid gelatinous fuels. AMERICAN COALINOIL CORP. Brit. 332,343, May 25, 1929. Mixts. consisting of finely divided solid fuels suspended in liquid fuels are stabilized by a material obtained by neutralizing with alkali all the product formed by blowing an oxidizing gas through a hydrocarbon oil heavier than kerosene in the presence of a catalyst such as an oleate, stearate or palmitate of a metal such as Al, Mn, Co or Zn. Numerous details and examples are given

Motor fuel. H. MENZ, W. STEFFEN and E. JAAKS-MÜNCHFBERG. Brit. 331,966, April 30, 1929. Tetrahydronaphthalene 50–55, sulfonated castor oil 10 and water 35–40 contg. sulfite lye 5 parts, or similar mixts. are stated to be suitable for use with a "hot spot" vaporizing device.

Fuel for internal-combustion engines. PHILIP S. DANNER and JOHN E. MUTH (to Standard Oil Co. of Calif.). U. S. 1,779,061, Oct. 21. A fuel suitable for use under high compression comprises a hydrocarbon material such as gasoline and a metal amino carbonyl compd. such as Fe diethylaminopentacarbonyl.

Operating internal-combustion engines with still hot pulverized coking products as fuel. HANS WAHL and ALBERT FISCHER (to I. G. Farbenind. A.-G.). U. S. 1,781,485, Nov. 11. An app. is described for pulverizing hot freshly coked material such as that derived from brown coal and feeding the pulverized material to an engine.

Use of inert gases in crank cases of internal-combustion engines to prevent explosions. ALLGEMEINE ELEKTRIZITÄTS-GES. Brit. 332,137, Oct. 20, 1928. An inert gas such as N or exhaust-engine gas may be used, with or without admixt. with a gas of distinctive odor such as NH_3 or mercaptan, to serve as a warning in case of leakage

Air filter for internal-combustion engines, etc. H. AUSTIN Brit. 331,718, July 31, 1929. Structural features.

Destructive hydrogenation. C. F. R. HARRISON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,548, April 2, 1929 H for use in destructive hydrogenation of coal, oils, etc., is heated under pressure by converting a portion of it into CH_4 by an exothermic reaction with CO in the presence of a catalyst A gas mixt. obtained from water gas by partial oxidation and removal of CO (leaving about 3–5% of the CO) may be used and the CH_4 formed may be removed from the gas by washing with oil. Numerous details of procedure are described.

Destructive hydrogenation. C. F. R. HARRISON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,817, April 2, 1929. Vapors produced from the destructive hydrogenation of carbonaceous materials such as coal and oils in the liquid phase are superheated in the absence of hydrogenating catalysts, and then passed, together with H, over a hydrogenating catalyst at a temp. lower than that of the superheating stage The superheating may be effected by contact with heating masses such as Al or Zn or their compds. and the catalysts for the final stage may include Fe, Ni, Mo, Cr, Sn or their compds. Various examples and details of procedure are given.

Destructive hydrogenation. C. F. R. HARRISON, H. W. STRONG and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 332,246, April 17, 1929. In destructive hydrogenation of coal or the like under high pressures, an aq. soln. of the catalyst such as Ni nitrate or NH_4 molybdate is sprayed over the material, which may then be mixed with oil and hydrogenated in the usual manner. Various details of procedure are described.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 331,916, April 11, 1929. Products leaving a destructive hydrogenation chamber in gaseous form are washed and the vapors simultaneously condensed by contact, while still under pressure, with a washing oil such as a hydrocarbon oil of high b. p., destructive hydrogenation products or the like. An example is given of the destructive hydrogenation of a middle oil fractionated from a brown coal low-temp.-distn. tar at a temp. of 450–70° under 200 atm. pressure in the presence of a catalyst prepd. from molybdic acid and ZnO, a washing oil b. about 200° being sprayed into the gaseous mixt. leaving the reaction chamber.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 332,251, Jan. 17, 1929. Heating of the material in reaction tubes or chambers is effected by external gaseous heating media having temps. at least 100° higher than the reaction temp. but below 800° and a uniform flow of heat to the charge is obtained either by scraping off coke deposits from the interior of the reaction tubes or chambers or by surrounding the tubes with a baffle or mantle to effect uniform heat distribution. Various details of app. and operation are described.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 332,336, May 15, 1929. Substances of high mol. wt. are removed from carbonaceous liquids such as middle oils, by adsorbents such as silica gel or alumina gel, and are destructively hydrogenated at elevated temp. and pressure while assocd. with the adsorbent. The adsorbent preferably carries a catalyst such as molybdic acid. Various details of procedure are given.

Thermal decomposition of finely divided carbonaceous solids. FRIEDRICH BARTLING. U. S. 1,781,659, Nov. 11. The material is subjected to destructive distn. while held in surface adhesion on a device such as a metal conveyer by an electrostatic charge. App. is described.

Apparatus for low-temperature carbonization. J. E. HACKFORD. Brit. 331,193, Dec. 21, 1928. A series of travelling carbonizing tubes is lined with paper pulp or other suitable medium to prevent sticking of the charge. Various details of construction and operation of the app. are described.

Low-temperature carbonization of solid fuels. C. PAMART. Brit. 331,497, March 2, 1929. For the production of semi-coke in granular or pulverulent state, the fuel is preheated to 300–350°, then partially oxidized and finally carbonized at 500–600° in a retort such as described in Brit. 268,613 (*C. A.* **22**, 1461).

Rotary retort for low-temperature carbonization, drying, etc. I. G. FARBENIND. A.-G. Brit. 331,879, Feb. 11, 1929.

Retort for carbonizing coal. T. M. DAVIDSON. Brit. 331,906, April 8, 1929. A tapered hollow structure extends into the fuel space so as to form a cavity in it through which the gases are withdrawn, and so as to cause arrangement of the charge in thin layers; this structure is arranged to be lowered for discharge of the coke, and various structural features are described.

Carbonizing non-bituminous or anthracite coals. G. M. F. F. MASCART. Brit. 331,850, April 8, 1929. Coal contg. not more than 14% of volatiles, agglomerated with not more than 7% of pitch, is subjected to a progressive carbonization for 9–10.5 hrs. at temps. rising from about 500° to about 900–930° (suitably in an externally heated retort) with injection of steam or with gas freed from by-products circulated upwardly through the material to generate H from the CH_4 present.

Carbonizing coal, etc. WALTER E. TRENT (to Trent Process Corp.). U. S. 1,781,613, Nov. 11. The material is passed through a distg. zone in individual charges in sep. containers attached to a conveyer and each container is provided with a heat-storage element such as a cast iron block which is preheated and supplies sufficient heat for the carbonization of the charge in the container. App. is described. U. S. 1,781,614, relates to distn. of finely divided coal by introducing it to a stream of combustion-supporting gas such as air and effecting partial combustion of the coal in the gas to generate sufficient heat to remove volatiles from and carbonize the comminuted coal; the carbonized coal particles are sepd. by discharging a portion of the lighter carbonized particles in suspension in the gas stream and withdrawing the remaining portion of the carbonized particles substantially undild. by the gas. App. is described. Cf. *C. A.* **24**, 4377.

Wet separation of coal, etc. C. W. H. HOLMES and BIRTLEY IRON CO., LTD. Brit. 331,841, March 8, 1929. Preliminary to sepn. of coal, ore, etc., from assocd. shale or other gang by immersion in a liquid of intermediate sp. gr. such as $CaCl_2$ soln. or $ZnCl_2$ soln., the material is sprayed with paraffin oil, crude varnish or other suitable coating substance to minimize wetting of the mineral by the sepg. liquid.

Gravity separation of coal with a calcium chloride solution. RUDOLF LESSING. U. S. 1,780,830, Nov. 4. Various details of app. and operation are described.

Improving the appearance of discolored coal. ERNEST V. COLLINS, JR. (to Delaware, Lackawanna & Western Coal Co.). U. S. 1,781,102, Nov. 11. The coal is treated with a soln. of NH_4 persulfate. U. S. 1,781,103 specifies the use for the same purpose of a soln. of HCl and $TiCl_3$. Cf. *C. A.* **24**, 1961.

Apparatus for "clouderizing" powdered fuel with air for combustion in furnaces or internal-combustion engines. C. H. VERITY. Brit. 331,221, March 12, 1929. Structural features.

System for conjointly burning relatively high-grade pulverized coal and relatively coarse low-grade fuel in furnaces. ARTHUR V. ADAMSON (to International Combustion Engineering Corp.). U. S. 1,778,744, Oct. 21. The different fuels are admitted to the furnace in alternately arranged streams of flattened configuration.

Preheating coal for coking. FRANZ PUENING (to Koppers Co.). U. S. 1,781,079, Nov. 11. Coal is subjected to preheating at a temp. in excess of 100° and which may be up to about 315° and the sensible heat of the preheated coal within the temp. range

mentioned is used for evapg. moisture from wet coal supplied for subjection to the preheating medium in advance of treatment with the latter. App. is described.

Bleached montan wax product. WILHELM PUNGS and MICHAEL JAHRSTORFER (to I. G. Farbenind. A.-G.). U. S. 1,780,633, Nov. 4. A bleached montan wax comprising esters and salts of the acids contained in the wax (the salts being present in quantity less than 25% the wt. of the wax) is prepd. by esterification with glycol or glycerol and is suitable for use in "shoe creams," etc. Cf. *C. A.* **24**, 2276.

Desuperheating steam. BRITISH ARCA REGULATORS, LTD., and T. LINDSAY. Brit. 331,361, June 12, 1929. Water which is to be brought into direct contact with steam to be desuperheated is first preheated by indirect contact with the steam.

Apparatus for purifying distillation gases such as those from coal, lignite, peat or tar. ALFRED JOSEPH (to Compagnie internationale pour la fabrication des essences et petroles). U. S. 1,780,159, Nov. 4. Various details are described of an app. in which purifying material such as Ni on a porous carrier for treating the hot gases is placed in an annular chamber, the inner and outer walls of which both serve for radiating heat.

Desulfurizing fuel gases. S. G. WATSON, D. M. HENSHAW and W. C. HOLMES & Co., LTD. Brit. 332,147, Oct. 15, 1929. Before removal of S by use of reagents such as suspensions or solns. of metallic oxides in alkalies, the hot gases are preliminarily treated with hygroscopic substances such as $CaCl_2$ soln. (which may have been previously used for removing moisture from purified gas) under such conditions as not to reduce the gas temp. below that at which the S-removing reaction proceeds satisfactorily, *e. g.*, 35–40°. Various details of treatment are described.

Desulfurizing gas. FREDERICK W. WERNER and ERNEST T. JOHNSTON. U. S. 1,779,024, Oct. 21. Producer or by-product coke gas or other gas contg. H_2S and N is purified by *forming Ca sulfide* and *synthesizing* NH_3 by bringing the gas into contact with CaO at a reacting temp. of dull redness. App. is described.

Gas-producer operation. H. J. F. PHILIPON. Brit. 332,366, June 15, 1929. In an ash-melting gas producer, the proportion of fixed C to the wt. of the charge is about 30%, and slag is formed from high ash content fuels or by addns. of substances having a base of silica, alumina or lime, a fusible slag being formed with a SiO_2 to CaO ratio of 0.9. The blast may be varied to produce temps. of 400–800° and low-grade cast iron may be added and transformed into siliceous cast iron free from S. Fe ores also may be added, as may also those of other metals, and various details and modifications of procedure are described.

Gas producer and boiler furnace operation. T. R. WOLLASTON. Brit. 331,488, March 27, 1929. Gas from a water-jacketed gas producer such as described in Brit. 316,749 (*C. A.* **24**, 1962) passes to one or more eccentrically arranged burners for heating a steam generator which is adapted to be heated by radiant heat and convective heat, various details of construction and operation being described.

Producer gas. REID POWER DEVELOPMENT CO., LTD., and J. W. HINCHLEY. Brit. 332,007, May 30, 1929. In production of a gas high in CO, gases from a lime kiln are passed through a producer and the quantity of gas or air or both admitted to the kiln and the quantity of air admitted to the producer are controlled according to the temp. in the kiln or in the producer. Various details of app. are described

Mixed oil and water gas. H. G. TERZIAN (to Humphreys & Glasgow, Ltd.). Brit. 331,756, Jan. 3, 1929. In operation of a carbureted water-gas set, after the air blast, oil is vaporized in the carburetor and superheater and passed back through the fuel bed, which is subsequently steamed, deposited carbon being removed. Various details of plant construction and operation are described. Cf. *C. A.* **24**, 2584.

Water gas. SYDNEY J. MCAULIFFE (to Fuller Lehigh Co.). U. S. 1,780,759, Nov. 4. Various details of app. and operation are described for gasifying pulverized coal and steam in admixture and suspension as a thin vertical sheet heated on both faces and the bottom edge.

Apparatus and heat-exchange system for liquefying gases such as constituents of natural gas. LEON B. STRONG (20% to Frank G. Campbell). U. S. 1,780,250, Nov. 4.

Waterless gas holder. W. BLAKELEY and FIRTH BLAKELEY SONS & CO., LTD. Brit. 331,266, March 25, 1929.

Waterless gas holder. FREDERICK H. WAGNER (to Bartlett Hayward Co.). U. S. 1,781,256, Nov. 11.

Cracking coal-tar constituents. MICHAEL MELAMID. U. S. 1,779,486, Oct. 28. Coal tars contg. both high b. p. constituents and lighter oils which can be cracked at comparatively low temps. are atomized with a H-contg. gas into a zone contg. a liquid metallic catalyst such as molten Sn, Bi or Sb and brought into contact with the catalyst at a temp. of about 300–400° to effect vaporization and cracking; unvaporized con-

stituents of high b. p. are continuously removed from the cracking zone and the gaseous products of the cracking are separately removed.

Centrifugal tar separator for separating tar from oil and steam, etc., under vacuum. GEORGE W. WATTS (to Standard Oil Co. of Ind.). U. S. 1,781,618, Nov. 11. Structural features.

Coke oven. ARNOLD BECKERS. U. S. 1,780,992, Nov. 11. Structural details.

Coke-oven battery. JOSEPH VAN ACKEREN (to Koppers Co.). U. S. 1,780,803, Nov. 4.

Vertical coking retort. JOSEPH BECKER (to Koppers Co.). U. S. 1,779,958, Oct. 28.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

Sources and distribution of major petroleum products, Atlantic Coast states, 1929. E. B. SWANSON. Bur. Mines, *Information Circ.* **6396**, 9 pp.(1930).—Atlantic Coast states received 177,063,000 bbls. of crude petroleum in 1929, an increase of 2,542,000 bbls. over 1928. This was from the following sources: tankers from Gulf Coast ports 56.38, tankers from foreign ports 38.97, tankers from California ports 0.38, withdrawal from foreign crude stocks 0.18, by pipeline from Illinois and Appalachian fields 3.30, and by pipeline from Mid-Continent fields 0.79%. This material was used as follows: domestic crude run to stills 59.97, foreign crude run to stills 37.41, burned directly as fuel 0.87, added to stock 0.38, exported 0.50%. These states received 133,831,000 bbls. of gasoline in 1929, an increase of 13,479,000 bbls. over 1928. The source of this material was as follows: Atlantic Coast refineries 43.23, tankers from Gulf Coast 31.99, tankers from Calif. ports 16.73, foreign ports 5.29, from Appalachian refineries 2.53, by tank cars from other areas 0.23%. Of this 92.17% was consumed in the Atlantic Coast states. ALDEN H. EMERY

The cracking of petroleums. ANDRÉ GRAETZ. *Chimie & industrie* **24**, 271–9, 526–43(1930).—A review dealing with the theory of cracking phenomena (effects of temp., time of treatment, pressure, reaction medium, chem. constitution of the hydrocarbons and their thermal dissocn.), describing the more important cracking processes which have found com. application, and discussing the probable evolution of the cracking industry in the near future. A. PAPINEAU-COUTURE

Crack Mexican stock at low pressures. G. EGLOFF AND E. F. NELSON. *Oil and Gas J.* **29**, No. 25, 38(1930).—In a com. run a Dubbs unit cracking Mexican kerosene was operated continuously for 23 days. The plant produced 64.9% of motor fuel of 60% benzene equiv., at 300 lb. pressure and 892°F. The same type of cracking units is handling residual stocks and heavy crude oils, with only minor changes in operating conditions. The cracked distillate is treated by the "split-plumbite" process, using 4% by wt. of acid. J. R. STRONG

A study on the oxidation phenomena of insulating mineral oils. I. S. MIZUSHIMA AND T. YAMADA. *Researches Electro-Tech. Lab., Tokyo, Japan* No. **291**, 18 pp.(1930).—A slight portion of S amounting to 0.1% was added to a refined white transformer oil and the oil was then tested for oxidation during 100 hrs. under the pressure of 86 cm. of Hg at 120°. The test of the oil without S was carried out parallel with this test. The oil without S oxidized readily, but the one with S added did not appreciably. Alkyl sulfides and mercaptans, when added to the oil, give the same antioxidation effect, while thiophene does not. Therefore M. and Y. consider that the stability toward oxygen of oils that are not highly refined must be attributed to the influence of S compds. contained in them. It is, however, another problem how the addnl. S influences the oils which are not highly refined and which produce sludge when oxidized There are 2 conflicting opinions with respect to the effect of S upon the sludge-forming character of the oil; namely, that it is acceleration, and that it is retardation. The authors' expts. made with 7 different kinds of oil show that in all cases the oil with 0.2% of S added formed more sludge than the oil without S added. Transformer oils that produce a large amt. of sludge always contain certain amts. of S and unsatd. compds. The authors also investigated the role of these S and unsatd. compds. in the oil in the formation of sludge. To obtain the oil with some unsatd. compds. but free from S, highly refined transformer oils were submitted to cracking at high temp. With the oils thus treated oxidation tests were carried out with and without addn. of S. In the cracked oil without S, sludge did not form, whereas acidity formation and the other phenomena which prove that oxidation has taken place remained nearly the same as in the un-

cracked oil; the cracked oil to which S was added gradually darkened in color, though its acidity did not increase, and finally the oil pptd. a remarkable quantity of sludge. The authors consider, therefore, that both the S and the unsatd. compds. are essential for the formation of sludge in the oil. W. OGAWA

Equipment and processes of crude oil dehydration. M. E. GARRISON. *Petroleum World and Oil Age* **27**, No. 10, 66–70, 137–8(1930).—The use of the Cottrell treater for de-emulsifying crude oils by passing the emulsion down through the elec. field between the shell and the central rotating shaft, bearing horizontal disks, involved serious fire risk and heavy losses of light oil fractions. The Petreco "H.F." (horizontal field) treater is closed and the oil enters at the bottom, clean oil collecting and being taken out at the top. The cone-shaped electrodes on the central shaft are moved up and down a short distance. A. c. is used and the water particles, becoming oppositely charged, coalesce. EMMA E. CRANDAL

Precautions necessary for cleaning sour crude storage tanks. R. B. ROAPER. *Natl. Petroleum News* **22**, No. 43, 47-B(1930). —All lines into the tank are blanked. The oil and some residual matter are floated out by a high-pressure stream of H_2O. The tank is steamed for 36–72 hrs. before the tank tester takes a sample for H_2S and combustible gases. Bottom plates are removed and the bottom settling is scraped out. The tanks are finally sand-blasted if necessary to remove FeS. R. W. KELLY

Physical analysis of oil sands. P. G. NUTTING. *Bull. Am. Assoc. Petroleum Geol.* **14**, 1337–49(1930).—A new form of precision pycnometer and new methods, together with a simple method of measuring permeability, are described. Common sources of error and the interpretation of results are discussed in some detail. A. H. E.

Oil shale from Picton County, Nova Scotia. A. A. SWINNERTON. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 13–24(1930). —Oil shales from 6 beds were assayed. Yields in gal. per ton, analyses of oil shale, shale oil, gas, spent shale and a products balance are given for each sample. ALDEN H. EMERY

Disintegration of kukkersite in organic liquids. K. LUTS. *Brennstoff-Chem.* **11**, 148–50(1930).—This and other oil shales exhibit swelling tendencies, gas evolution, and subsequent disintegration of structure upon immersion in various org. solvents. Gas pressure produced by penetration into capillaries, the size of which has been calcd., is believed responsible. The compn. of sieved residue fractions is given. The speed of disintegration is proportional to the heat of wetting and also depends on the surface tension. Russian, Estlandish and Scottish shales and bituminous limestone have been investigated with ether, acetone, $CHCl_3$, C_5H_5N, CS_2, EtOAc, MeOH, EtOH, aniline, benzine, petroleum, acetophenone, nitrobenzene and C_6H_6. F. W. J

Some characteristics of absorption oils and factors governing their use. C. D. GARD. *Petroleum World and Oil Age* **27**, No 10, 82–6, 93, 95(1930).—It can be shown by calcn., with the aid of a Kremser absorption factor, that, for the same gasoline production, only 64.5% as much absorption oil of 42° A. P. I gravity is necessary as if the oil were of 35° A. P. I. gravity. It is very important for efficiency of absorption that operations be so conducted as to leave no C_4H_{10} fraction in the lean oil. When high-pressure and low-pressure absorbers are used in combination, the high-pressure oil-gas ratio can be so adjusted by expt. as to give max. absorption of C_4H_{10}. E. E. C.

Gasoline survey for 1928. P. V. ROSEWARNE AND R. J. OFFORD. Can. Dept. Mines, Mines Branch, *Rept.* **712**, 57–68(1930). —Analyses are given of 77 samples of gasoline collected from 13 Canadian cities in Aug., 1928. The quality was superior to that sold in the 3 previous yrs. The variation in quality was slightly less than that in 1927. The quality was also superior to that of gasoline sold in the U. S. in July, 1928. ALDEN H. EMERY

Gas flow charts for the calculation of main line capacities. M. V. COUSINS. *Petroleum Eng.* **2**, No. 2, 186, 188, 189(1930).—Three simplified charts for the calcn. of pipe line characteristics are presented. CHAS. WIRTH

Inorganic lubricants. III. Mixtures of aqueous liquids with non-reacting solids. WILLIS A. BOUGHTON. *J. Am. Chem. Soc.* **52**, 4335–6(1930); cf. *C. A.* **24**, 4382.—Successful lubricants for ground-glass surfaces can be made by suspending finely divided non-reacting solids in aq. solns. of hygroscopic salts. Kaolin or graphite suspensions in a $CaCl_2$ soln. gave the best results. EMMA E. CRANDAL

Vegetable oils (as lubricants) for airplanes and automobiles. N. CHAMPSAUR. *Chimie & industrie* **24**, 519–25(1930).—A discussion of the merits of vegetables oils (more particularly olive, colza and peanut) for the lubrication of airplane and automobile engines, from both the technical and the (French) national standpoints. Following a review of the theory of the lubricating power of oils, to show the superiority of vegetable over mineral oils, results are given of preliminary bench and road tests with

olive oil which showed, among other advantages, that the motor developed more power than with mineral oil; this oil is also more unctuous, has a better viscosity-temp. curve (lower ratio of viscosities at low and high temps.), and has better decarbonizing properties. The only drawback noted was the relatively high solidifying pt., which requires special precautions when starting up the motor in cold weather. A. P.-C.

The manufacture of soluble cutting compounds. S. J. CAPLAN. *Petroleum Eng.* 2, No. 2, 95(1930).—Formulas for a sol. cutting oil and a sol. cutting paste are given. CHAS. WIRTH

The estimation of gritty constituents in greases. EWALD PYHÄLÄ. *Petroleum Z.* 26, *Motorenbetrieb und Maschinen-Schmierung*, No. 9, 3-4(1930).—A grease of excellent quality appears, when molten, as a clear, homogeneous, viscous liquid that contains no suspended matter. No gritty material should be present. No method for the detn. of solid impurities in greases has been included in the report by the German Assocn. for Testing of Technical Materials; a method has, therefore, been devised for the quant. estn. of all the important constituents. The grease (20 g.) is thoroughly shaken with petr. ether (I). A part dissolves, the soaps are suspended in another layer while the grit, lime and sand settle out. This layer is sepd. by decantation and filtration, washed, dried and weighed. The soln. layer and filtrate are refluxed with alkali and the free acid content is detd. Distn. of the soln. leaves the mineral oil originally in the grease as a residue. The soaps are taken up in warm 96% alc. The sol. soaps are retained when the alc. is distd. off. The alc.-insol. soaps, removed by filtration, washed, dried and weighed, are suspended in I. Upon acidification, an inorg. sludge, SiO_2 or H_2SiO_3, settles out. The wt. of the sludge is subtracted from that of the insol. soaps to obtain the true content of the latter. A com. grease so analyzed contained 3.8% SiO_2, signifying that a soap contg. Na_2SiO_3 or a silica-gel residue was used in its manuf. The grit was observed when the grease was rubbed between the fingers. I. M. LEVINE

***l*-Rotatory turpentine from Pinus sylvestris.** V. KRESTINSKIĬ AND L. BAZHENOVA-KOZLOVSKA. *Zhur. Prikladnoĭ Khim.* 3, 681-9(1930).—The turpentine had the following compn.: α-pinene 69%, camphene 5, carene fraction 14.5, phellandrene 1.5, alcs. and sesquiterpenes 10. All components were *l*-rotatory. V. KALICHEVSKY

Composition of turpentines from Pinus sylvestris. V. KRESTINSKII, A. LIVEROVSKII AND V. MALMBERG. *Zhur. Prikladnoĭ Khim.* 3, 533-40(1930); cf. *C. A.* 23, 4564.—Turpentine distd. in the presence of alkalies had the following consts.: d_{20} −0.8660; α_D +13.64°; coeff. of rotatory dispersion α_V/α_J = 1.13 and α_F/α_C = 2.01; n_D^{20} 1.47163; dispersion $n_g - n_c$ = 0.01624. Careful fractionation showed the presence of only 2 hydrocarbons: α-pinene and Δ^3-carene. The latter was *l*-rotatory. The residue from turpentine distn. had a cryst. structure. It was washed with alc. and recrystd. from $CHCl_3$ contg. MeOH. A fairly good yield of small white crystals (m. 51°) was obtained. Similar crystals from the last alc. washings had m. p. 53–4°. Their empirical formula was detd. as $C_{10}H_{20}$. A small quantity of another cryst. substance (m. 90°) was also detected in the alc. washings. The steam-distd. turpentine (d_{20} 0.860, α_D +12.60°; α_V/α_J = 1.087; α_F/α_C = 1.99) contained 68% α-pinene, 19% Δ^3-carene, 3% alcs., 10% sesqui- and poly-terpenes and residue. Differences in chem. compn. of these samples from those previously reported are due to the relative freshness of stumps used in this work. V. KALICHEVSKY

Composition of the alcoholic fraction of turpentines. V. KRESTINSKII, F. SOLODKII AND G. TOLSKII. *Zhur. Prikladnoĭ Khim.* 3, 691-8(1930); cf. *C. A.* 22, 4564.—The alc fractions of turpentines from *Pinus sylvestris* contain α-pinene, Δ^3-carene, *d*-camphor, probably terpinenol-4, a satd. alc., a sesquiterpene (m. 82–3°) and apparently cadinene (m. 114–5°) as well as other components. The work is being continued. V. KALICHEVSKY

Technical method for manufacturing terpinol from Russian turpentines. A. K. SHUMEIKO. *Zhur. Prikladnoĭ Khim.* 3, 541-53(1930).—The use of 65% H_2SO_4 is recommended. The max. permissible temp. is 5°. The yield is approx. the same for H_2SO_4: turpentine ratios of 1:1.5-4.0. Good contact speeds up the reaction. Complete directions are given. V. KALICHEVSKY

The danger of explosion in the overcompression of tar oils by means of compressed air (LEYMANN, WEBER) **24.** Preparation of sulfuretted balsam-like masses from wood tar (PALLAS) **17.** A new viscometer (Schaffer) **1.** Polymerizing olefins (Brit. pat. 331,186) **10.** Apparatus for separating oil from gas (U. S. pat. 1,780,101) **1.** Pressure filter for filtering oil (U. S. pat. 1,780,663) **1.** Destructive hydrogenation (Brit. pat. 331,548) **21.** Cement for cementing off oil wells, etc. (U. S. pat. 1,781,267) **20.** Pressure filter for oil (U. S. pat. 1,780,723) **1.**

Fractionation of petroleum oils. EUGENE H. LESLIE and EDWIN M. BAKER. U. S. 1,780,977, Nov. 11. Oil is introduced into a section of a fractionating column in which ascending vapor comes into intimate contact with descending liquid. Condensed vapor is introduced at the top of the app. and liquid is collected in the sections and liquid products are independently withdrawn from one or more sections. The liquid residue from the fractionating column is distributed over a confined packing zone such as one filled with rings or jackstones to volatilize a portion of the liquid residue and the unvolatilized portion is allowed to pass through another confined packing zone, and steam is injected into the liquid flowing from the packing zones and volatilized vapors thus formed are passed into the bottom of the fractionating column. Various details of app. are described.

Electric apparatus for dehydrating petroleum oils. HAROLD C. EDDY (to Petroleum Rectifying Co. of Calif.). U. S. 1,779,695, Oct. 28. Structural features.

Petroleum still and furnace setting. DAVID S. JACOBUS (to Babcock & Wilcox Co.). U. S. 1,779,434, Oct. 28. Various structural details are described of a still setting comprising superposed drums and a bank of heating tubes.

Fractional condensation of petroleum and other vapors. A. LOSEY, P. GOTTLIEB and L. L. HAUPT. Brit. 331,526, Oct. 10, 1928. Vapors from the distn. of petroleum, oil shale, coal, wood, tar, etc., are passed into a heat engine to develop power and then further passed successively through a condensate sepg. chamber and through turbines and intermediate condensate sepg. chambers further to develop power and sep. fractions of successively higher b. p. An arrangement of app. is described.

Breaking petroleum emulsions of the water-in-oil type. MELVIN DE GROOTE and LOUIS T. MONSON (to Wm. S. Barnickel & Co.). U. S. 1,780,343, Nov. 4. A demulsifying agent is used comprising wood sulfite liquor material and a sulfonic demulsifying material such as a propylated naphthalenesulfonic acid. Cf. *C. A.* **24**, 4145 and following abstr.

Breaking petroleum emulsions of the water-in-oil type. MELVIN DE GROOTE, LOUIS T. MONSON and ARTHUR F. WIRTEL (to Wm. S. Barnickel & Co.). U. S. 1,780,344, Nov. 4. A demulsifying agent is used comprising an amylated aromatic compd. such as an NH_4 amylated aromatic sulfonate characterized by capability of producing an insol. ppt. with a sol. alk. earth salt. U. S. 1,780,345 describes the use of a demulsifying agent contg. a substituted aromatic detergent-forming sulfonic compd. of the type X F R SO_3 Z, in which X is a polycyclic aromatic nucleus, F is a detergent-forming org. residue, R a residue of an alc. contg. less than 12 C atoms and substituted in the aromatic ring, and Z a "H ion equiv." Cf. *C. A.* **24**, 4145 and preceding abstr.

Cracking petroleum oil. ROBERT T. POLLOCK (to Universal Oil Products Co.). U. S. 1,781,128, Nov. 11. Decompn. of the oil is effected in more than 2 successive stages and in each stage at least 3 products are formed: gasoline-like constituents, intermediate products and residual products. The gasoline-like constituents and residual products formed in each stage are removed and in each succeeding stage the cracking of the intermediate products only of the preceding stage is continued. Various details of app. and procedure are described.

Cracking asphaltic or other petroleum residues. J. H. BREGEAT. Brit. 331,531, March 27, 1929. Oils of lower b. p. are obtained from materials such as asphaltic petroleum residua, low-temp. carbonization tars, acid sludges from petroleum refining, waxes and natural asphalts by heating in a retort to 350-460° with continuous agitation, with or without addn. of abrasive material, returning the distillate b. above 300° to the retort and regulating the distn. so that the hourly products comprise 5-14% by wt. of the retort contents. Various details and modifications of procedure are described.

Cracking heavy hydrocarbons. EUGENE A. PRUDHOMME (to Soc. international des procédés Prudhomme (S. I. P. P.). U. S. 1,780,536, Nov. 4. An atomized charge such as a heavy oil is cracked alternately in one of a pair of heated chambers contg. a catalytic purifier such as a metal or "oxymetallic" catalyst and the resulting products are condensed and sepd. from residual gases. The mass of hydrocarbon material to be atomized is heated by returning the heavy fractions of the condensed products to the mass, and the residual gases are employed for atomizing the charge; coke deposited during the cracking is burned in one chamber while the cracking operation is carried out in the other chamber, and the heat thus generated is employed for heating the residual gases. App. is described.

Conversion of heavy hydrocarbons. ADOLPHE A. F. M. SEIGLE. U. S. 1,779,828, Oct. 28. In a method comprising a preheating stage for vaporizing the raw hydrocarbons, a main heating stage with regular and gradual heating of the vapors formed in the preheating stage, these vapors and the gases also produced are successively sub-

mitted to the action of catalyzers such as turnings of Fe, Al, Cu and ferro-Ni, the max. temp. being 500–700° and the pressure being below 1.2 kg. per sq. cm.; the gases and vapors from the heating stage are subjected to successive cooling stages in the first of which the cooling medium used is boiling water at such a superatm. pressure that the sudden drop in the temp. of the gases and vapors through the first cooling stage will be substantially between 250° and 450°. U. S. 1,779,829 describes a generally similar process in which the condensate of each cooling stage from the second stage on is reheated and revaporized and again submitted to the action of the previous cooling stage. App. is described.

Apparatus for cracking hydrocarbons by use of heat and electric discharges. Louis B. Cherry (to C and C Developing Co.). U. S. 1,779,356, Oct. 21. A conduit for the passage of hydrocarbon vapors and gases embodies several reaction tubes connected in series, heating flues arranged longitudinally and exteriorly of the tubes and provided with means for independent temp. control and with means for maintaining high-frequency elec. discharges in the tubes.

Apparatus for fractionating and cracking hydrocarbon oils. L. DeFlorez. Brit. 331,940, April 17, 1929. Numerous details of construction and operation are described.

Cracking hydrocarbon oils. Carbon P. Dubbs (to Universal Oil Products Co.). U. S. 1,779,465, Oct. 28. Untreated oil is brought into contact with cracked oil vapors just following cracking of the latter in the vapor phase; following this, the oil is subjected to a mild cracking temp. in a heating zone and then delivered to a vaporizing zone from which vapors and liquid oil are removed before the cracking operation has proceeded to the extent of forming coke; vapors from the vaporizing zone are subjected to a cracking temp. while in the vapor phase to supply the cracked oil vapors for treating incoming untreated oil. App. is described. Cf. *C. A.* **24**, 3108.

Cracking hydrocarbon oils. C. P. Dubbs. Brit. 331,569, March 5, 1929. In the operation of a cracking app. comprising a heating coil, sepg. zone and dephlegmator, with continuous withdrawal of residual oil, polymerization of residual oil in the sepg. zone is controlled by keeping the level of the oil as low as possible and by regulation both of the rate of withdrawal and dissipation of heat. Numerous details of app. and procedure are described.

Cracking hydrocarbon oils. G. F. Forwood, J. G. Taplay and United Kingdom Oil Co., Ltd. Brit. 332,285, April 18, 1929. Oil to be cracked is passed in vapor phase and under low pressure (suitably 30–40 lbs. per sq. in.), mixed with steam, through a conversion chamber contg. a heated catalyst (suitably at a temp. of 450–650°) consisting of a porous vegetable charcoal impregnated with Na Al silicate. Various details are given of the app. used and method of prepg. the catalyst.

Cracking hydrocarbon oils. Eugene C. Herthel and Edward W. Isom (to Sinclair Refining Co.). U. S. 1,781,390, Nov. 11. Oil is forced from a bulk supply tank, through a heater and back to the supply tank and is maintained at a cracking temp. throughout the cycle; vapors from the bulk supply are passed through a reflux tower and reflux from the latter is pumped into the oil circulating from the bulk supply tank at a point between the main circulating pump and the heater. App. is described. Cf. *C. A.* **24**, 5148.

Fractional distillation of hydrocarbon oils. Claude W. Watson (to Texas Co.). U. S. 1,780,286, Nov. 4. The oil is passed through a battery of series-connected stills provided with fractionating towers in which the oil is exposed to progressively increasing temps.; vapors from the stills are subjected to fractionation in the fractionating towers, and vapors from the first several stills are condensed and collected to form a distillate contg. the more volatile constituents of the oil charge; the charge is divided into a larger and a smaller portion, the smaller portion is introduced as a reflux medium to those fractionating towers corresponding to the stills from which the distillate fractions mentioned are obtained, and the larger portion of the charge is introduced into the first still of the series. Various details of app. are described.

Apparatus for distilling hydrocarbon oils. Harry G. Schnetzler (to Standard Oil Co. of Ind.). U. S. 1,779,918, Oct. 28. For dividing material such as naphtha condensate into definite proportions for partial refluxing, a horizontal weir is provided over which the liquid flows and a plurality of partitions adjacent the weir spaced at predetd. distances divide the flow over the weir; the withdrawal of the divided flow of liquid may be regulated by valved conduits. Various details of the app. are described.

Dehydrating hydrocarbon oils. Wm. L. Palmer (to National Dehydrator Corp.). U. S. 1,781,076, Nov. 11. A relatively rapid short oscillatory motion is imparted to a flowing stream of oil contg. water (suitably by oscillating plates mounted on a shaft) in order to effect demulsification. App. is described.

Desulfurizing hydrocarbon oils. CLARENCE J. FRANKFORTER (to Frankforter Oil Process, Inc.). U. S. 1,780,873, Nov. 4. Liquid hydrocarbon oils and distillates contg. S and S compds. are treated with water gas or other gas contg. H activated by contact with a heated material such as platinized pumice and the materials are subjected to further activation together in contact with heated material such as a Ni-Cr elec. resistance to convert the major portion of the S and S compds. present into volatile sulfides and the latter are sepd. App. is described.

Apparatus for extracting hydrocarbon oils with alcohol. THEODORE A. WERKENTHIN (to Solar Refining Co.). U. S. 1,781,420, Nov. 11. An app. is described adapted for passing heavy petroleum oil into an extracting vessel under automatic control and feeding substantially anhyd. alc. in vapor form to extract the oil; a portion of the vaporized alc. is passed into a condenser employing a cooling medium such as water and the temp. of the cooling medium is automatically controlled so that the alc. vapors will be condensed only at a predetd. temp., the condensed alc. being returned to the extn. vessel. U. S. 1,781,421 relates to an extn. process carried out in this manner in similar app. Cf. *C. A.* **24**, 4146.

Distilling mineral oil. FRANK TINKER (to Sinclair Refining Co.). U. S. 1,779,222, Oct. 21. One stream of raw oil is passed through a fire-heated heating zone into a mixing zone and heated to distn. temp in the heating zone; a hot oil mixt. including this heated raw oil is passed from the mixing zone to a sepg. zone, residuum is discharged from the sepg. zone, vapors are taken off from the sepg. zone and these vapors are partially condensed by heat exchange with an independent stream of the same raw oil, and this heated independent stream of raw oil is introduced into the mixing zone where it merges with the first-mentioned oil stream. An arrangement of app. is described.

Converting mineral oils into products of lower boiling point. HERBERT R. ROWLAND (to C & C Developing Co.). U. S. 1,779,402, Oct. 21. Vapors of the oil are subjected to the action of a high-tension a c discharge of frequency not exceeding 10,000 cycles per sec. at a temp. favorable for conversion of the vapors into products of lower b. p., and the products of lower b. p. are separately recovered. App. is described.

Refining light oil from coal distillation. JOSEPH J. LAWTON (to Semet-Solvay Co.). U. S. 1,779,944, Oct. 28. The crude light oil is washed with H_2SO_4, the resulting acid sludge is sepd. from the washed oil, the oil is treated with NH_3 to neutralize residual acid, and low b. p. constituents are sepd. from the neutralized oil by direct steam distn. in the presence of neutralization liquid, thus breaking up emulsions present and preventing the decompn. and volatilization of any S compds. present in the neutralized oil.

Heat-exchange apparatus suitable for use in oil refining, etc. JOHN P. RATHBUN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,779,890, Oct. 28. Structural features.

Flue-gas-recirculating apparatus for oil-refining shell stills. HARRY A. ATWATER. U. S. 1,779,405, Oct. 28. Structural features.

Furnace for burning acid sludge. FRANK J. MCDEVITT. U. S. 1,780,653, Nov. 4.

Destructive hydrogenation. H. W. STRONG and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,816, April 2, 1929. Vapor of higher b. p. oils such as middle oils is passed with H over a catalyst mass of Fe coated with Zn and then over a porous mass of Fe_2O_3 or equiv., such as a product produced by heating Fe_2O_3 in H at 500°. Pressures of at least 20 atm. and temps. of 400° or higher are preferred. Various details of app. and procedure are described.

Destructive hydrogenation. H. G. WATTS and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 331,509, April 2, 1929. "Benzines" produced in destructive hydrogenation are condensed and the gases are simultaneously washed and freed from lower paraffinic hydrocarbons by cooling the products under pressure in intimate contact with the condensed "benzines" (suitably in a packed tower, which, with assocd. app., is described).

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 331,558, Jan. 7, 1929. Distillable materials such as petroleum oils are destructively hydrogenated under a pressure of at least 20 atm. in the presence of a catalyst contg. at least three different constituents, an oxide of group 2 of the periodic system, or of group 3 or a compd. of the latter of suitable character, together with oxides, hydroxides or sulfides of different metals such as Co, Ni and metals of groups 5 and 6. Several examples with details of procedure are given.

Refining "cracked gasoline." EUGENE C. HERTHEL (to Sinclair Refining Co.). U. S. 1,781,388, Nov. 11. In a process comprising passage of the gasoline vapors through an adsorptive catalyst such as fuller's earth where the polymers thus produced

exceed 3% by liquid volume of the refined gasoline product, the raw cracked gasoline vapors are passed through the catalyst and polymerization of undesirable unsatd. components is thus effected without sepn. or discharge of the polymers from the operation, and the total resulting vapor mixt. including the polymers is then passed directly to a rectifying zone and constituents including polymers and of higher b. p. than desired in the gasoline are condensed and light constituents from the condensed polymer mixt. are vaporized in the rectifying zone in a rectifying column (various features of app. being described).

Column and plate apparatus for fractional distillation of gasoline or other materials. WAYNE Z. FRIEND (to Baltimore Gas Engineering Corp.). U. S. 1,780,818, Nov. 4. Structural details.

Tanks for fuels such as gasoline tanks of aircraft. HERMAN T. KRAFT (to Goodyear-Zeppelin Corp.). U. S. 1,779, 397, Oct. 21. A layer of rubber compn. is placed over a frame of open construction and the inner surface of the rubber is coated with a material insol. in hydrocarbons, such as gelatin, leaving the inner surface of the framework (which may be formed of metal bars) directly exposed to the fuel.

Separating greasy and waxy materials from distillates, etc. JOHANN K. PFAFF, KURT BÖTTGER and ADOLF SIEWEKE (to Deutsche Gasolin A.-G.). U. S. 1,779,287, Oct. 21. See Fr. 677,385 (*C. A.* **24**, 3110).

Paraffin. AKTIEBOLAGET SEPARATOR-NOBEL, N. O. BACKLUND and K. G. MALM. Brit. 331,961, April 26, 1929. Paraffin is sepd. from liquid hydrocarbons by chilling, diluting, and centrifuging in a centrifuge arranged for mechanically carrying away the paraffin, as described in Brit. 296,805 (*C. A.* **23**, 2567), and after this the liquid is passed through a centrifuge without a mech. conveyor to sep. further paraffin, the latter centrifuge being run at a higher speed than the first. Various details of app. and operation are described.

Apparatus for heating oils to remove water from them. JAMES J. FEARIS. U. S. 1,781,632, Nov. 11. Various details are described of app. which may be heated by steam and is suitable for the treatment of petroleum.

Apparatus for demulsifying oils and tars containing water by heat, baffling and gravity. FREDERICK H. WAGNER (to Bartlett Hayward Co.). U. S. 1,781,257, Nov. 11. Structural features

Bituminous emulsions. GEORGE S. HAY (to Flintkote Roads, Inc.). U. S. 1,778,760, Oct. 21. An aq. dispersion is formed comprising bitumen-pitch particles as the dispersed phase and water as the continuous phase, and contg. in the external phase substantially less than 10% of water-sol. org. nonelectrolyte such as glycerol or allyl alc. capable of suppressing the freezing point of the emulsion so as to prevent injury to the emulsion due to freezing (although freezing may occur) at temps. below 0°.

Edge filter for oil of motor vehicles. BRITISH TOOL & ENGINEERING CO., LTD., and A. JONES. Brit. 331,815, April 2, 1929. Structural features.

Lubricant. JOHN A. HIGGINS (to Emma Higgins). U. S. 1,780,157, Nov. 4. A composite lubricant which is suitable for use at high or low temps. comprises a mixt. of about 1 lb. of rubber dissolved in gasoline, about 25 gals. of a neutral mineral lubricating oil and about 8 oz. of coconut oil, added to and mixed with about 50 gals. castor oil mixed with about 50 gals. of cottonseed oil.

Lubricant. OTTO C. SCHMIDT. U. S. 1,780,315, Nov. 4. A lubricant suitable for use on roll necks in cold roll-steel mills comprises paraffin wax, petroleum oil and sheep-wool grease. Soda, lime and soapstone may also be added.

Lubricants. FELTON S. DENGLER (to Texas Co.). U. S. 1,781,444, Nov. 11. Lubricants which are suitable for use under high pressures are prepd. by reducing a paraffin base crude petroleum by distn. without substantial decompn. until the residue has a flash test within the range of about 190° to 250°, the residual oil being then immediately brought into contact with a current of air at temps. between about 205° and 270°, in order to effect a desired degree of limited oxidation.

Lubricant suitable for use in drawing and die-pressing. FRANK F. STAMBERG (to Standard Oil Co. of Ind.). U. S. 1,781,607, Nov. 11. Oil such as straw oil is mixed with green acid soap, colloidal clay and water.

Apparatus for deaerating lubricants by vacuum treatment. DRYSDALE & CO., LTD., and J. W. W. DRYSDALE. Brit. 331,950, April 22, 1929. Structural features.

"Chatterless" lubricating oil. THEODORE W. DOELL and EDWIN N. KLEMGARD (to Standard Oil Co. of Calif.). U. S. 1,781,167, Nov. 11. A complex Pb salt of unsatd fatty acids and naphthenic-like acids such as Pb oleate and naphthenate is dissolved in lubricating oil to form a lubricant suitable for use in automobile engines with planetary transmissions.

Reconditioning used lubricating oil. W. D. HARRIS and R. V. AYCOCK. Brit. 331,290, April 10, 1929. See U. S. 1,745,167 (*C. A.* **24**, 1498).

Reconditioning used lubricating oils such as those from internal-combustion engines. J. C. PATRICK. Brit. 331,876, April 10, 1929. After removing water (suitably by settling), the water-free oil is heated and agitated with H_2SO_4, the oil is sepd. from sludge and the volatile constituents are vaporized by heating to a temp. below that at which the oil would be distd. or cracked, an adsorbent such as fuller's earth is added and the supernatant oil is drawn off. CaO or BaO may be added to the fuller's earth.

Purifying used oil such as that from steam turbine lubrication. LEO D. JONES (to Sharples Specialty Co.). U. S. 1,778,831, Oct. 21. Used oil carrying sludge, water-sol. impurities and impurities which are sol. in the oil at higher temps. and which ppt. at temps. to which it is cooled for re-use is treated with water and cooled, and then centrifuged. An arrangement of app. is described.

Filter and electro-magnet device for separating metallic particles from oil used in lubricating internal-combustion engines. ARCHIE M. NIVEN (to Continental Motors Corp.). U. S. 1,778,910, Oct. 21.

Conditioning waste for use as journal-box packing. EDWIN S. PEARCE (to Railway Service and Supply Corp.). U. S. 1,779,010, Oct. 21. Unoiled waste is subjected to a gaseous medium such as heated air and then to a liquid medium such as oil, both of which serve for removing lint. U. S. 1,779,011 describes a process in which treatment with lubricating oil serves to sep. lint.

Reclaiming used journal-box waste. EDWIN S. PEARCE (to American Laundry Machinery Co.). U. S. 1,779,104, Oct. 21. The waste is soaked in a bath of hot oil and centrifuged while still hot. App. is described.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The celluloses from different natural sources. NAOHIKO MATSUNAMI. *Chem. News* **141**, 200–1(1930).—See *C. A.* **24**, 5479. E. J. C.

Method for determining the degree of purity of cellulose fibers. M. FREIBERGER, Z. v. VASS AND L. HONIG. *J. Soc. Dyers Colourists* **46**, 111–8(1930).—The present methods of detg. the degree of purity of cellulose fibers are discussed and 2 new quant. methods given. In Method I the material is extd. with boiling caustic soda and this ext. is oxidized with $K_3Fe(CN)_6$ and the excess of the latter back titrated with thiosulfate. The $K_3Fe(CN)_6$ used is termed the ferricyanide no. and the equiv. is termed the O no. For materials with lower ferricyanide nos. Method II is used. In it the material is heated in an open test tube with caustic soda and $K_3Fe(CN)_6$ and the excess of the latter back titrated. It is assumed that oxidation in these methods is limited to the easily sol. reducing compds. present in the modified cellulose. Charts and tables of results and the effect of variations in the process on the results are included. T. G. H.

Old and new conceptions of cellulose constitution and their experimental basis. KURT HESS. *Kolloid-Z.* **53**, 61–75(1930).—H. leans to the conception of cellulose as represented by Meyer and Mark (*C. A.* **23**, 1263) who modify the formula of E. Fischer and B. Tollens in the light of modern data. ARTHUR FLEISCHER

The use of nitrogen tetroxide in the nitration of cellulose. L. A. PINCK. *Ind. Eng. Chem.* **22**, 1241–3(1930).—A method has been developed for the nitration of cellulose with N_2O_4. The factors influencing the degree of nitration have been studied. Sufficient data have been obtained for the prepn. of any of the nitric esters of cellulose used in commerce. PAUL S. BILLINGTON

Action of hypoiodite solution on cellulose preparations. K. HESS, K. DZIENGEL AND H. MAASS. *Ber.* **63B**, 1922–7(1930).—Bergmann and Machemer have recently proposed a method of detg. the av. mol. wt. of cellulose prepns. which is based on the oxidizing action of 0.1 *N* hypoiodite soln. (*C. A.* **24**, 2877). They assume that the I no. (cc. 0.1 *N* I consumed by 1 g. substance) corresponds to the oxidation to CO_2H of the CHO group of the end glucose member of a primary valence chain. A prerequisite of such a method of detg. mol. wts. is the homogeneity of the prepns., and it is by no means certain that the cellulose prepns. in question are homogeneous, since they tenaciously retain cellobiose, among other substances. Moreover, since the prepns. are of unknown constitution, it is difficult to establish a basis for the process and a series of assumptions must be made, the correctness of which it is not easy to test. The reac-

tion with cellulose prepns., unlike that with sugars, which B. and M. used for comparison, is heterogeneous, and the I nos. found represent mol. wts. only on the assumption that the undissolved or colloidally dispersed phase reacts molecularly with the reagent according to the stoichiometric relation $RCHO + O = RCO_2H$. Weltzien and Nakamura found that the Cu no. cannot be used in studies of the constitution of cellulose prepns. because it depends on the degree of dispersion of the cellulose in the Cu soln. This led the authors to test the applicability of the I no. method. In the first place, with a biosan acetate m. 260–70°, $[\alpha]_D^{20}$ —16.0°, AcOH content 62.32% sapond. in the usual way with 2 *N* NaOH in alc. (ash content of the sapon. product 0.1%), it was found that the I no. increased from 3.73 after the 20 min. prescribed by B. and M. to 6.94 after 16 hrs. Again, if the sediment is carefully washed with H_2O after the titration and again treated with the alk. I soln. it once more uses up I, and this is also true if the sediment, after washing, is dried in a high vacuum over P_2O_5 at 100° before being again titrated, although in this case the amount of I consumed is smaller. To test the applicability of the I no. method advantage was also taken of the fact that the less pure carbohydrate prepns. remain dissolved or nearly dissolved in dil. NaOH if they are first dissolved in more concd. NaOH and then correspondingly dild. An acetate which in 0.5 *N* NaOH gave an I no. of 5.74 yielded a value of 7.33 when dissolved in half the same vol. of *N* NaOH and then dild. with an equal vol. of H_2O, and the carbohydrate recovered from the latter expt. again consumed I when once more treated with the reagent. C. A. R.

Effect of concentrated sulfuric acid on cellulose. TETSUKICHI KATAYAMA AND M. SENGOKU. *Repl. Osaka Ind. Research Lab., Japan* **11**, No. 7(1930).—The effect of various concns. of H_2SO_4 upon the phys. and chem. properties of cellulose has been studied. F. I. NAKAMURA

The saccharification of cellulose according to Scholler. E. GUNDERMANN. *Centr. Zuckerind.* **38**, 835–6(1930).—A discussion. J. F. LEETE

Existence of the cellobiose residue in cellulose. W. N. HAWORTH, E. L. HIRST AND H. A. THOMAS. *Nature* **126**, 438(1930).—Under mild conditions of treatment at low temps., fully methylated methylcellobiose undergoes cleavage to give a diacetylhexamethylcellobiose, which is readily transformed into cryst. heptamethyl-β-methylcellobioside. The exptl. conditions under which this deriv. of cellobiose is isolated preclude its occurrence as a reversion product of the reaction. Moreover, the yield of the cryst. β-cellobioside is equal to that of cellobiose octaacetate obtained by the direct acetolysis of cellulose. These facts increase the evidence for the view that cellobiose is preformed in cellulose. LOUISE KELLY

Cellulose acetate and acetate rayon from wood pulp. FRITZ OHL. *Kunstseide* **12**, 189–91(1930); *Jentgen's Rayon Review* **2**, 224–6(1930).—Expts. are described on the prepn. of cellulose acetate from wood pulp (I) and the spinning of rayon therefrom. Although the results are of a preliminary nature, they show that the acetylation of I is possible. The properties of the pulp required for this purpose are different from those required for the manuf. of viscose and moreover the properties of the rayon may be favorably affected by suitable spinning conditions. I which was used in the acetylation was first freed from tar and fat by treatment with a mixt. of equal parts of EtOH and CCl_4, from pentosans with hot 6% NaOH soln. and finally with 17.5% NaOH soln. O. points out that the qualities of cotton that are important from the standpoint of acetate rayon are difficult to control and that, if only a correct procedure is found for the acetylation, it should not be difficult to produce consistently a suitable cellulose of standard quality from I and at the same time gain chem. and economic advantages. FREDERICK C. HAHN

Strained viscose threads—a chemical test and its mechanism. A. J. HALL. *Rayon Record* **4**, 1099–101(1930).—H.'s belief is that the residual S is made more accessible by the stretching for reaction with the alk. $AgNO_3$. A. K. JOHNSON

Rayon—today and tomorrow. ROBERT E. HUSSEY AND PHILIP C. SCHERER, JR. *J. Chem. Education* **7**, 2543–70(1930). E. H.

Rayon of fine denier. A HERZOG. *Kunstseide* **12**, 170–3, 221–2(1930); *Jentgen's Rayon Review* **2**, 202–5, 238–40(1930).—On the av., cuprammonium rayon (I) filaments are the finest in cross-section, but several of the nitro rayons (II) examd. were finer than I. Fluctuations in the titers of fibers were the greatest with II and smallest with cellulose rayon (III), I and viscose rayon (IV) being intermediate in this regard. Variations in the titer are greater than the degree of irregularity in the diam. of single filaments As regards fullness of cross-section the following order exists: III > IV > II > I. A comparison is given of the various dimensions of various artificial and natural fibers. FREDERICK C. HAHN

Spinning machine for fine rayon. E. SCHURZ. *Kunstseide* **12**, 234–8; *Jentgen's Rayon Review* **2**, 205–9(1930).—A review and discussion of the mechanism of spinning and a description of the construction of a spinning machine for fine rayon. F. C. H.

Progress report on waste sulfite liquor. GUY C. HOWARD. *Ind. Eng. Chem.* **22**, 1184–5(1930).—The process consists of a fractional pptn. by a lime reagent by which the liquor is sepd. into an inorg. product for use in making fresh liquor, an org. product for boiler fuel, and a tail-liquor effluent which is discharged into the sewer. P. S. B.

"Bontaka" fiber from Madagascar—its value as a paper-making material (HEIM DE BALSAC, *et al.*) **25.** Röntgen rays in fiber research (MARK) **25.** The physical chemistry of starch and bread making. IV. Paste formation in starch and mercerization of cellulose (KATZ, DERKSEN) **2.** Solvent recovery by absorption in *m*-cresol, silica gel [in the rayon industry] and activated C (OHL) **13.** Dialyzing and pervaporating membranes (U. S. pat. 1,779,942) **18.** Cr- or Cr-alloy-plating of paper-making apparatus (Brit. pat. 331,196) **9.** Impregnating cellulosic material with synthetic resins (Brit. pat. 331,851) **26.**

α-Cellulose. LAURI I. L. DURCHMAN. U. S. 1,780,347, Nov. 4. Wood chips are cooked with black and white sulfate liquor with the addn. of Na_2SO_3 in the proportion of 0.8–1.0% based on the air-dry wt. of the wood chips, and the cooking is continued for a longer time than is usual in the sulfate process, thus increasing the α-cellulose content, followed by treatment of the pulp with a soln. contg. 2–6% NaOH and 2–6% NaCl.

Cellulose acetocrotonates. SOC. DES USINES CHIMIQUES RHONE-POULENC. Brit. 331,260, Dec. 31, 1928. Cellulose or a "near transformation product" is treated with crotonic anhydride in the presence of HOAc and a catalyst with or without a solvent or diluent, to produce mixed esters of various compns. and properties. Various details and examples are given. Cf. *C. A.* **24**, 5306.

Fibrous sheet material from cellulose partially converted into xanthate. JAMES C PEABODY and ALFRED BROWN (to Frank B. Hopewell, trustee). U. S. 1,781,668, Nov. 11. Fibrous material such as wood-pulp fiber is incompletely converted into cellulose xanthate to convert the fibers into a swollen condition and render them gelatinous and insol. in water or dil. NaOH soln., and the material may be formed into sheets as in paper manuf.

Cellulose esters. FRANZ BECKER, HEINRICH HEIMANN and ALFONS BAYERL (to I. G. Farbenind. A.-G.). U. S. 1,780,151, Nov. 4. A cellulosic material such as cotton is treated with HNO_3 vapor, and then treated with an esterifying agent such as Ac_2O, HOAc and H_2SO_4. The preliminary treatment with HNO_3 serves to facilitate production of cellulose esters of a very low viscosity.

Films of cellulose esters and ethers, etc. G. FRENKEL. Brit. 332,255, Feb. 18, 1929. The first layer of a composite film is made so thin (suitably about 0.01 mm) as to require a very short time for drying and after being stripped from its support is used as a carrier band for addnl. layers, which may comprise various cellulose esters or ethers, shellac, resin, etc.

Threads and filaments of cellulose acetate or other cellulose organic esters or ethers. BRITISH CELANESE, LTD., H. DREYFUS and W. I. TAYLOR. Brit. 331,229, Dec. 20, 1928. Products of increased strength are produced, in a process involving use of a counter-current of evapg. medium in the spinning cell, by applying a uniform controlled stretch where the product still contains residual solvent and is in a semi solid or plastic condition (preferably while contg. 20–40% solvent). App. is described.

Cellulose ether esters. I. G. FARBENIND. A.-G. Brit. 331,903, March 28, 1929. A cellulose ether contg. 0.5–1.5 alkyl groups (calcd. on the mol. $C_6H_{10}O_5$) and comprising also a small proportion of benzylcellulose is acetylated with Ac_2O in the presence of HOAc as solvent together with a small quantity of a customary catalyst such as H_2SO_4. Instead of the benzylcellulose, a substituted benzyl deriv. such as a nitro- or bromo-benzyl cellulose may be present. "Monoethyl-1½-acetylcellulose" contg. about 1% of benzyl, obtained by this method, is sol. in acetone, acetic ester and chlorinated hydrocarbons and suitable for the manuf. of films and threads.

Cellulose ethers. MAX HARTMANN (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,777,970, Oct. 7. Alkali cellulose is caused to react with an aliphatic monohaloalkylamine such as chloroethyldiethylamine. Numerous examples are given.

Viscose. SAMUEL WEIN (one-half to Nathan Raff). U. S. 1,779,521, Oct. 28. After forming a sol. cellulose xanthogenate, S compds. are removed from the product

before pptg. the viscose, as by treatment to form insol. compds. contg. Zn. Various details of procedure are described.

Treating freshly spun viscose fiber cakes. LEWIS A. PALEY. U. S. 1,779,103, Oct. 21. Sol. impurities are washed from the cakes with water and they are then treated with a hot soln. contg. Na_2CO_3 in order to remove resins, org. S compds., etc. App. is described.

Artificial silk from viscose. THEODOOR KOCH. U. S. 1,781,018, Nov. 11. Viscose is used contg. PhCl which serves to reduce the luster of the product. $C_6H_4Cl_2$ may also be used.

Artificial silk, etc. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 332,187, Jan. 5, 1929. Various products comprising cellulose esters or ethers are incorporated, during or after their production, with a solvent or gelling agent and subjected to a treatment with substantially dry steam to improve their resistance to the delustering action of hot aq. liquids or steam. Numerous details and examples are given.

Centrifugal box, etc., for spinning artificial silk in practically continuous operation. WM. P. DREAPER. U. S. 1,780,346, Nov. 4. Structural features.

Treating black liquor from soda and sulfate pulp manufacture. EDWARD G. GOODELL. U. S. 1,779,535, Oct. 28. Partially concd. black liquor is sprayed into heated gaseous medium to form a dried powder of substantially the same org. content as the liquor, the powder is burned in a sep. operation and the heat developed is utilized in dehydration of further quantities of the liquor. App. is described.

Treating black liquor from pulp manufacture. EDWARD G. GOODELL. U. S. 1,779,768, Oct. 28. A solid product is prepd. consisting of compressed solid constituents of black liquor substantially unchanged in chem. compn. and suitable for transport.

Treating black liquor from pulp manufacture. LINN BRADLEY and EDWARD P. MCKEEFE (to Bradley-McKeefe Corp.). U. S. 1,779,226, Oct. 21. Black liquor from pulp manuf. with use of NaOH as cooking liquor is sulfited with $NaHSO_3$ to form Na_2SO_3 and the sulfited liquor is incompletely causticized, to produce a soln. contg. both NaOH and Na_2SO_3 and which may be used for further wood digestion. NaOAc may be recovered by concn. and crystn. Cf. *C. A.* **24**, 4158.

Dehydrating black liquor from pulp manufacture. EDWARD G. GOODELL. U. S. 1,779,536, Oct. 28. A dried black liquor product and concd. black liquor in finely divided form are heated and the resulting volatile gases are burned so as to heat a steam generator; hot gaseous products of combustion, in a sep. operation, are passed into contact with concd. black liquor in finely divided form substantially to dehydrate the black liquor without substantial change in its org. content and without substantially satg. the gaseous medium, the dehydrated black liquor is recovered as a finely divided practically moisture-free powder, and the unsatd. gaseous medium is passed into contact with relatively unconcd. black liquor to effect its concn. and the powder and a portion of the concd. black liquor are supplied for the first-mentioned heating step. An arrangement of app. is described.

Regenerating black liquor from pulp manufacture. EDWARD G. GOODELL. U. S. 1,779,537, Oct. 28. A portion of black liquor is subjected to spray burning under oxidizing conditions in a zone closely above and near the surface of a bed composed of the solid products of combustion of the black liquor and spray-dried black liquor solids when introduced as such in admixture with Na_2SO_4 (the black liquor solids when introduced being substantially dry and of high org. content) and heat of combustion from the org. material present serves for driving off water from the sprayed black liquor to permit its combustion without use of other fuel, while the org. matter present under the conditions obtaining serves for reduction of sulfate present to sulfide. An arrangement of app. is described.

Cellulose pulp. HARRY L. HORN (to Bagasse Development, Inc.). U. S. 1,780,750, Nov. 4. Materials such as bagasse, straws, grasses, wood or cornstalks are simultaneously cooked, beaten and electrically and chemically treated to prepare a pulp suitable for *paper* or *rayon manuf.*

Cellulose pulp. HARRY L. HORN (to Bagasse Development, Inc.). U. S. 1,779,971, Oct. 28. Material such as bagasse, straws, grasses, wood or cornstalks is digested with water and steam and treated with an elec. current in an app. which is described.

Digestion of fibrous materials such as wood chips. THOMAS L. DUNBAR. U. S. 1,781,447, Nov. 11. In digestions such as the treatment of wood chips with sulfite liquor, side relief liquor is caused to flow from a digester undergoing cooking directly into a digester undergoing filling, and the side relief liquor is utilized for packing the chips evenly in the digester. An arrangement of app. is described.

Wood fiber. GEORGE A. RICHTER (to Brown Co.). U. S. 1,780,539, Nov. 4.

Previously liberated wood fiber of non-coniferous origin such as that from beech or birch is digested at about room temp. in a soln. of alk. compds. such as NaOH soln. in order to improve the softness, tear resistance and suitability of the material for use in *rayon manuf.*

Wood pulp high in α-cellulose. LAURI I. L. DURCHMAN. U. S. 1,781,449, Nov. 11. In order to render water-sol. incrusting substances in chemical wood pulp such as that obtained by the sulfate or soda process, the pulp is treated for 4 to 6 hrs. at 20 to 60 lbs. pressure with a soln. contg. 2–5% NaOH and 1–3% Na_2SO_3.

Bleaching wood pulp. GEORGE A. RICHTER and MILTON O. SCHUR (to Brown Co.). U. S. 1,780,943, Nov. 11. Unbleached sulfite pulp is treated with Cl water and then bleached in a bleach liquor maintained distinctly alk. throughout the bleaching, such as in hypochlorite soln. contg. NaOH and contg. sufficient "bleach" to whiten the pulp.

High-speed rotary-disk mill for producing wood pulp, etc. BAUER BROS. CO. Brit. 331,567, March 5, 1929. Structural features.

Sulfite pulp. GEORGE A. RICHTER (to Brown Co.). U. S. 1,780,842, Nov. 4. Raw cellulosic materials such as wood chips are heated under pressure with a soln. comprising sulfurous acid and $(NH_4)_2SO_4$ and which may contain other NH_4 and Na salts.

Sulfite paper pulp. ROBERT B. WOLF. U. S. 1,780,638, Nov. 4. In the recovery of acid in the sulfite-pulp process, a const. pressure is maintained in the relief line from the digester, the gases and liquids are cooled and are then discharged from the relief line into an acid absorbing medium. App. is described.

Beater for paper pulp. ALBERT J. ALLISON (to Simonds Worden White Co.). U. S. 1,778,710, Oct. 21. Structural features.

Paper-pulp beater. WALTER N. SHERWOOD. U. S. 1,780,845, Nov. 4. Structural features.

Storage tank, with agitating pump, etc., for liquids such as paper pulp. JOSEPH E. BOND. U. S. 1,780,166, Nov. 4. Structural features.

Pulp beating or refining "engines" of the Jordan or similar type. T. D. NUTTALL and BENTLEY & JACKSON, LTD. Brit. 331,992, May 21, 1929. Structural features.

Paper-making apparatus. EDWARD J. CROWSON. U. S. 1,779,087, Oct. 21. Structural features.

Paper-making apparatus. W. H. MILLSPAUGH. Brit. 332,125, Sept. 14, 1929. Structural features.

Suction cylinders for paper-making apparatus. H. BANNING. Brit. 332,170, Jan. 24, 1929. Structural features.

Composition for waterproofing paper. CHARLES S. SHELTON. U. S. 1,778,964 Oct. 21. ZnO 12, Pb oxide 3, dammar gum 5 and a mixt. of benzol and petroleum-ether about 82 parts.

Paper carrying ornamental or protective substances, etc. I. G. FARBENIND. A.-G Brit. 331,707, July 22, 1929. Coloring or loading materials, suspensions of fibers, etc., for security paper or the like, are applied (by feed pipes of an app. which is described) to paper pulp at a place on the wire cloth of the paper making app. at which no matting of the pulp has taken place.

Apparatus for continuous drying of webs such as coated paper. CARLE J. MERRILL. U. S. 1,779,611, Oct. 28. Structural features.

Coated paper. WM. W. MCLAURIN. U. S. 1,780,793, Nov. 4. The greater part of the surface of one side of paper is coated with a relatively hard non-adhesive material such as a mixt. of clay, blanc fixe, satin white, coloring and sizing which facilitates printing, and an adjacent portion of the surface is coated with a softer non-adhesive material such as a similar mixt. contg. also glycerol or glucose which facilitates folding. App. for coating is described.

Coated paper. CHAMPION COATED PAPER CO. Brit. 331,578, April 5, 1929. In the prepn. of a coated paper suitable for book and magazine printing, a coating mixt. in a plastic condition (suitably formed from clay 200 lbs. and 15 gals. of a soln. of casein 1.5 lbs. per gal. of ammonia water, made up to a total of 30 gals., together with 0.5 gal. of water-soap mixt. contg. 20% of NH_4 stearate) is applied to the surface of the paper and is partly or completely hardened on the surface of the paper in contact with a polished Cr surface or other suitable material to give a smooth finish to the coating on the paper. Various details of different materials which may be used are given.

Colored or tinted parchment paper. ROBERT I. COWEN. U. S. 1,780,616, Nov. 4. The formed paper is passed through an acid bath in which is dissolved a dye and the

paper is then passed through a water bath to wash out acid present in the paper. Several examples are given.

Marbling paper and similar processes. G. M. BROWN. Brit. 332,190, Feb. 15, 1929. In marbling paper or in other similar operations, the material traverses past a fixed station over a trough contg. a liquid medium, such as water or a soln. of Carragheen moss, on which a film of pigment, varnish or lacquer (or a mixt. of these of different colors) is floated so that successive portions of the length of the material come into contact with the liquid and take up coating substances. App. is described and various examples given of the substances used for coating.

Marking carbon paper. HAROLD W. A. DIXON (to Columbia Ribbon & Carbon Mfg. Co.). U. S. 1,780,007, Oct. 28. The desired mark is applied to the supporting paper or tissue in an alkali soln. such as an alc. soln. of NaOH or KOH and the paper or tissue is thereafter coated with carbon ink.

Rubberized paper. ERNEST HOPKINSON (to Mechanical Rubber Co.). U. S. 1,779,772, Oct. 28. After removing moisture from a web of paper pulp, a top size is applied contg. dispersed rubber, and the web is dried to form a sheet.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

A new method for the preparation of tetryl. LOUIS DESVERGNES. *Chimie & industrie* (Paris) **24**, 785–93(1930).—Tetryl has heretofore been made by nitration of dimethylaniline. D. obtains it by nitration of monomethylaniline. An account is given of several methods of making the monomethylaniline of its step-by-step nitration, and of the several products obtained. CHAS. E. MUNROE

Determination of the explosive limits of gases and gas mixtures. H. LÖFFLER. *Brennstoff-Chem.* **11**, 145–6(1930).—A *micro-gas calorimeter* is described, consisting of a vacuum-jacketted glass explosion sphere contg. the thermometer bulb and the spark-gap of a flashlight-cell operated induction coil using an A-filled indicator tube. Capillary tubing with suitable stopcocks connects the sphere with a calibrated water-jacketed buret, Hg leveling bottle and CaO tube with porous glass filters. Less than 10 cc. of gas is required for calorimetric analysis with an error not greater than 0.33%. Explosive limits of gas-air, gas-O_2 and complete combustion mixts., CO_2 content of gases before and after combustion, and measurement of pressure reductions due to condensation of H_2O formed can be detd. A schematic diagram of the app. is given together with graphical data showing the progression of explosive limits of the gas evolved from a Fischer-Schrader coal-assay retort. F. W. JUNG

The danger of explosion in the overcompression of tar oils by means of compressed air. LEYMANN AND H. WEBER. *Zentr. Gewerbehyg. Unfallverh.* **17**, 134–9(1930); *Chimie & industrie* **24**, 587(1930).—The causes of these explosions are as yet but little known; they are ascribed either to the evolution of heat which causes decompn. of the lubricating oil, or to the fact that the Fe sulfide is heated to redness. In certain cases, however, absence of Fe sulfide was noted. In 3 such cases studied by L. and W. the preponderating factor was really Fe sulfide. In 1 case the real cause of the explosion lay in the introduction of water in the boiler; this sudden introduction of water can be prevented by the use of water separators. These explosions can be prevented by using N or some other gas contg. no readily exchangeable O for compressing the oil, or by compressing it by means of a pump instead of a gas. To avoid the formation of Fe sulfide as much as possible, the app. can be Pb-lined; Fe sulfide can also be eliminated from the washing oils by centrifuging and by treating with the min. quantity of Pb oxide. Attempts were also made to decrease the heating to redness of the Fe sulfide by the use of liquid paraffin or other very adherent oil with high b. p. A. PAPINEAU-COUTURE

Report on the causes and consequences of an explosion at Lyme Colliery, Haydock, England. F. H. WYNNE. Mines Dept. H. M. Stationery Office, London, 1930, 23 pp.—An excellent description of a mine explosion due to fire damp set free and ignited by a blast in the coal. It contains a verbatim record of an eye witness to the firing of the shot who survived the accident which is a most extraordinary event. CHARLES E. MUNROE

Sea batteries for firing submarine mines (Brit. pat. 332,265) **4.** Electrodes for sea batteries for firing explosive mines (Brit. pat. 332,233) **4.**

Liquid oxygen explosives. HERBERT C. BUGBIRD. U. S. 1,779,530, Oct. 28. Carbonized lignin residues are leached substantially to free them from alk. and water-sol. substances and the residue is used as an absorbent for liquid O to form an explosive.

Liquid oxygen explosives. HERBERT C. BUGBIRD. U. S. 1,781,214, Nov. 11. In prepg. an absorbent for liquid O, leached carbonized lignin residues are treated with a void-filling material such as carbon black.

Priming composition for explosives. JOSEPH D. MCNUTT (to Winchester Repeating Arms Co.). U. S. 1,779,820, Oct. 28. PbO_2 20–40, $Ba(NO_3)_2$ 3–10, Hg fulminate 30–45 and pentaerythritol tetranitrate 3–15%. U. S. 1,779,821 specifies $Ba(NO_3)_2$ over 40, Hg fulminate about 35, a Pb thiocyanate about 16, $BaCO_3$ 2 and charcoal 2%. Cf. following abstr.

Priming mixture for explosives. JOSEPH D. MCNUTT (to Winchester Repeating Arms Co.). U. S. 1,779,851, Oct. 28. Hg fulminate (contg. 16% water) 475, $Ba(NO_3)_2$ 240, Sb sulfide 255, trinitrotoluene 30 and diphenylamine 0.5–2 parts. Cf. *C. A.* **24**, 5160–1 and preceding abstr.

Gelignite and gelatin dynamite. ROY L. HILL (to Atlas Powder Co.). U. S. 1,778,718, Oct. 21. Pelleted alkali metal nitrate is used as an ingredient.

Smokeless powder. FRANCIS I. DUPONT (to U. S. F. Powder Co.). U. S. 1,780,911, Nov. 11. A colloidal nitrocellulose propellant powder is formed which contains a substance of water-sol. but non-solvent character such as glycerol which serves to stabilize the moisture content.

Blasting cartridges containing solid carbon dioxide and heating and firing devices. D. HODGE. Brit. 332,196, April 11, 1929. Structural features.

Coating cartridges with ceresin or other hard waxy materials. JOHN D. PEDERSEN. U. S. 1,780,566, Nov. 4. Preheated metal cartridges are passed through a bath of a soln. of the coating material and thence through a drying chamber.

Hand grenades. R. OSTERMEYER. Brit. 331,804, Jan. 25, 1929. A hand grenade fired by a slow-time fuse carries an auxiliary charge for generating an irritant such as tear gas, which is ignited before the bursting charge (with the intent of preventing an enemy from picking up the grenade and throwing it back).

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Interesting sources of natural dyestuffs. C. D. MELL. *Textile Colorist* **52**, 460–3, 535, 538–9, 551, 603–5(1930); cf. *C. A.* **24**, 4935.—The color changes in the fruit of the pica pica, which is a member of the Sterculiaceae family, are described. The chem. nature of these coloring substances is not known. The following are discussed as possible sources of natural dyestuffs: the several species of the North American walnuts for brown dyes; the eucalyptus for dyes and tannin; the *Cordia myxa* of India for a green dye; the European larch for tannins and dye; red sandalwood for a red dye; the *Carapa* species for tannin and dyes; the lignum vitae trees for blue and green dyes; the teak tree for a yellow dye; the mangrove swamps of the Philippine Islands for tannin; the bark of the *Soymida* of India for dyes and tannins. R. K. WORNER

Should the dyestuffs industry seek new dyes? P. J. SISLEY, JR. *Tiba* **8**, 1034, 1045, 1169–73(1930).—A brief review of the various types of dyeing, discussing the dyes that are still wanting or those that should be replaced by others better suited for the purpose. The dyeing of wool, cotton, silk, viscose rayon, acetate rayon and mixed fabrics is treated. A. PAPINEAU-COUTURE

Newer dyes for acetate rayon. GEORG RUDOLPH. *Kunstseide* **12**, 198–9; *Jentgen's Rayon Review* **2**, 216–7(1930).—A discussion of the dyeing properties of the Celliton dyes. FREDERICK C. HAHN

Dyestuffs for rayon—progress of British dye industry. ANON. *Rayon Record* **4**, No. 20, 1049–53(1930).—A résumé based on a report of the British Dyestuffs Industry Development Comm. Numerous British patent no. references are given. A. K. J.

Dyes and textiles in Britain, 1930. JAMES MORTON. *Chemistry and Industry* **49**, 818–26(1930). E. H.

Indigo. KENNETH MACKENZIE. *Dyestuffs* **31**, 33–8(1930).—The properties and application of indigo are given. CHAS. E. MULLIN

Note upon the coupling of diazonium compounds with 2-methoxy-3-naphthoic acid. G. B. JAMBUSERWALA AND F. A. MASON. *J. Soc. Dyers Colourists* **46**, 339–41(1930).—

Diazonium salts will couple with the alkyl ethers of phenolic substances in glacial acetic acid soln., the product being usually a mixt. of the methoxy and hydroxy dyestuff. MILTON HARRIS

Rapid fast colors in the printing of textiles. H. GÜRTLER. *Tiba* **8**, 1233–9(1930).—An outline of the possible applications of Fast Rapid Colors in the printing of textiles, describing the technic of their use under various conditions. A. P.-C.

Color standardization will not impair branding in color. WALDON FAWCETT. *Am. Dyestuff Reptr.* **19**, 684–6(1930).—Mass color, that is, color that envelops substantially the whole of an article of commerce, cannot be registered in the Patent Office. However, it is common practice to register a relatively narrow cap, ring or band of color. MILTON HARRIS

Patent law and the dyer. C. HOLLINS. *J. Soc. Dyers Colourists* **46**, 333–7(1930).—The advantages and disadvantages of patenting a dye or dyeing process are given. MILTON HARRIS

Matching colors by machinery. J. F. SPRINGER. *Textile Colorist* **52**, 466–70 (1930).—A description and discussion of the "Colorscope," recently developed by H. H. Sheldon (*C. A.* **24**, 5596) and W. A. Schneider. R. K. WORNER

Modern practices in dyeing, bleaching and finishing. M. A. GOLRICK. *Cotton* **94**, 1013–6, 1217–20(1930). R. K. WORNER

Some bad dyeing and its causes. NOEL D. WHITE. *Textile Colorist* **52**, 452–3, 486(1930).—Examples are cited of poor dyeing due to hard water, iron in the water, impurities in the water not removed by filtering system, and incomplete removal of soap. R. K. WORNER

Sulfur color dyeing. E. P. DAVIDSON. *Proc. Am. Assoc. Textile Chem. Colorists* 1930, 249–52; *Am. Dyestuff Reptr.* **19**, 709–12(1930).—S dyes are decidedly sensitive to variations in temp., vol. and duration of dyeing. Goods or yarn should be boiled in soda ash or caustic soda and sulfonated castor oil for cleansing. S color dyeings may be oxidized by air, Na perborate or a mixt. of Na dichromate and acetic acid. The most important operation is washing after dyeing. Washing in 1–2% of Na acetate will prevent tendering. MILTON HARRIS

Dyeing of acetate rayon. HERBERT BRANDENBURGER. *Kunstseide* **12**, 173–7, 223–8(1930); cf. *C. A.* **24**, 1985.—A discussion of acetate rayon dyes from the standpoint of fastness to water and washing, and to light. Dyes produced by diazotization appear to be the best in regard to fastness to water and washing, suspension dyes (I) and water-sol. dyes (II) being inferior and almost of like value. From the standpoint of light fastness, however, I is the best, II being next. FREDERICK C. HAHN

Dyeing of acetate rayon. HERBERT BRANDENBURGER. *Jentgen's Rayon Review* **2**, 209–16, 251–4(1930).—See *C. A.* **23**, 4575. FREDERICK C. HAHN

The function of electrolytes in the dyeing of cotton by means of substantive dyes. P. LIVET. *Tiba* **8**, 263–73, 391–7, 527–33, 651–63, 775–87, 907–17, 1023–9, 1155–9 (1930).—The 1st part of the article is devoted to a review of the present status of our knowledge of the constitution of cotton cellulose and of the various published works which gives an insight into the nature of solns. of substantive dyes; the 2nd part is devoted to personal exptl. results. *Modifications undergone by the cotton fiber during dyeing.*—The effect of temp. was not studied because, at the present time, there is no satisfactory method available for the purpose. By Meunier and Rey's method for the investigation of swelling (centrifuging under given conditions, weighing, drying and weighing again), it was found that 0.1–1.0 *N* $Ca(CNS)_2$ and NH_4CNS at atm. temp. reduced the swelling slightly as compared with that produced by distd. H_2O; Na_2CO_3 gave similar results, both alone and in the presence of varying quantities of NaCl. Wetting agents ("Nekal," at a concn. of 0.02%) appreciably reduced the swelling, particularly in the presence of NaCl. By analogy from the behavior of gelatin gels, it is concluded that the permeability of cotton toward diffusible ions and mols. and the rate of diffusion of the latter increase with the degree of swelling of the cotton. *Method for the detn. of substantive dyes in soln.*—The method adopted consists essentially in titrating with $TiCl_3$. *An app.* is described by which the various solns. (including the indicator) are kept in an atm. of CO_2 and the titration is carried out at the b. p. in an atm. of CO_2. Dyes which are completely decolorized by $TiCl_3$ can be titrated directly, as described by English (*C. A.* **14**, 3794) and serve as indicator. If the dye is not completely decolorized by reduction with $TiCl_3$, an excess of the latter is added and the excess titrated with ferric alum, a 0.1% soln. of methylene blue which has been exactly decolorized with $TiCl_3$ being used as indicator. The indirect method is preferable to the direct, particularly with dye baths contg. reduction products of the dyes having

undergone prolonged heating in the presence of salts in the course of the dyeing process. The method is fairly rapid, as 8–12 detns. can be carried out in 1 hr. *Action of electrolytes on soln. of substantive dyes in the cold and at boiling temp.*—Comparison of the pptg. action of NaCl, NaOAc and Na_2SO_4 on Congo red and benzoazurine G showed that, for equal normalities, AcONa had the greatest pptg. power, followed in order by NaCl and Na_2SO_4. The inactivity of Na_2SO_4, particularly towards Congo red, is remarkable and is contrary to the theory of Biltz (Biltz and von Vegesack, *C. A.* **4**, 3038), according to which the pptg. power of an electrolyte should increase with its degree of dissocn. Na_2CO_3 was found to have a pptg. power considerably greater than that of Na_2SO_4 but slightly less than that of NaCl, which also contradicts Biltz' theory, as Na_2CO_3 is less dissocd. than Na_2SO_4. NaOH was not found to have any greater protective or dispersive power than Na_2CO_3. Though it might seem logical to admit that those dyes which have the smaller particles and diffuse more rapidly are less sensitive to the action of electrolytes, expts. with chrysophenine (mol. wt. 680, diffuses very rapidly), diamine blue 2B (mol. wt. 916, diffuses with medium rapidity) and Congo red (mol. wt. 696, does not diffuse appreciably) on the one hand, and with NaCl, Na_2SO_4 and NaOAc on the other, showed that this is not the case, and that the action of the electrolytes in any particular case depends on the nature of the dye. *Effect of the progressive addn. of electrolytes during the dyeing of cotton: effect of the nature of the water used for washing.*—The quantity of dye fixed with increasing quantities of electrolyte increases, rapidly at first, and then more and more slowly, finally reaching a max. at fairly high concns. of electrolyte. All the electrolytes studied had about the same effect on the amt. of dye fixed when added during the dyeing at the same mol. concn. In spite of its alky , Na_2CO_3 does not behave differently from the other salts and does not modify the rate of fixation of the dye on the fiber. Variations, due to electrolytes, in the quantities of the dyes which are fixed on the cotton are caused by the effect of the salts on the size of the particles of dye. It is curious to note that the differences observed in the effect of different electrolytes on solns. of substantive dyes, which effect is certainly due to variations in the size of the dye particles, are not felt in the course of the dyeing. The nature of the water used for washing after dyeing affects the quantity of dye fixed. When Rhone water is used, more dye is fixed than when distd. water is used, the difference being due to the Ca salts present in the natural water. The amt. of dye which bleeds out during washing increases with the concn of electrolyte in the dye bath. On studying the effect of the cation of the electrolyte, no appreciable difference was observed in the action of K, Na and NH_4 salts of the same acid; it would seem, however, that K gave the max. and Na the least fixation. *Effect of electrolytes on the dyeing of mercerized cotton.*—The swelling of mercerized cotton in water and the quantity of dye which it fixed increases with the concn. of the mercerizing soln., which confirms the results obtained by Knecht with benzopurpurin 4B. The increase in swelling is considerable as compared with the increase in tinctorial affinity. *Comparative effect of electrolytes on the dyeing of boiled, immunized and sthenosized cotton* —Immunized cotton and sthenosized cotton, which swell much less in water than the alkali-cellulose or the cotton cellulose from which they were prepd., fix very little color on dyeing. On the other hand, the fixation of substantive dye is not directly proportional to the swelling power of the fiber. *Dyeing in the cold with substantive dyes.* —On dyeing at atm. temp. the amt. of dye fixed is the same as in operating hot, but the rate of fixation is much slower. *Irreversibility of fixation of substantive dyes by cotton and theory of dyeing in this particular case.*—From the preceding results L. concludes that the dyeing of cotton by substantive dyes cannot be explained exclusively by means of any of the theories admitted so far, and he considers that: (1) Part of the dye, possibly the greater portion, is fixed by diffusion of the ions into the thickness of the fibers and by internal polymerization which is favored by a higher Na-ion concn. inside the fiber than outside. At this point the state of swelling of the fibers comes into play, for the greater the swelling the easier and more rapid will be the diffusion of the dye. (2) Pseudo-adsorption, or superficial dyeing, also comes into play, chiefly in the fixation of the larger particles. (3) It is undisputable that the free alc. OH groups exert at least some attraction, as shown by the difference in the behavior toward substantive dyes of ordinary cotton and of immunized cotton. A. PAPINEAU-COUTURE

Dyeing of fast colors on loose wool, shoddy, slubbing and pieces. JOHN EMGE. *Dyestuffs* **31**, 17–22(1930).

CHAS. E. MULLIN

Emulsions—their preparation and applications. ALAN A. CLAFLIN. *Am. Dyestuff Reptr.* **19**, 697–700(1930).—The value of the colloid mill is pointed out. The prepn. of cleansing emulsions using volatile solvents, as xylene, dichloroethyl ether *o*-dichlorobenzene, are given. In throwing oil for silk and knitting oils for silk and rayon

the necessary lubrication must be detd. Phenol and cresols reduce surface tension of oils. MILTON HARRIS

The efficiency of the hydroextractor. FRED. GROVE-PALMER. *Am. Dyestuff Reptr.* **19**, 681–4(1930).—The efficiency of the hydroextractor depends on the quantity of liquid in the batch at the time of loading; the size of the cage; the no. of revolutions per min.; the fiber and the weave of the cloth; the temp. of the liquid and of the dyehouse. MILTON HARRIS

Functions of a laboratory in a finishing plant. J. A. CLARK. *Cotton* **94**, 1318–9, 1324(1930).—The functions discussed are (1) control of operations; (2) control of chem. supplies; (3) exptl. technical development; and (4) furnishing technical advice. R. K. WORNER

The isoelectric point and its relation to textile chemistry. T. G. HAWLEY, JR., AND M. HARRIS. *Am. Dyestuff Reptr.* **19**, 720–1(1930); cf. *C. A.* **24**, 2154.—The isoelectric point is defined and discussed. Dyeing, degumming and soly. of silk and wool are explained in terms of the isoelec. point. MILTON HARRIS

Spectroscopic investigation of the mineral constituents of textiles. SAMUEL J. LEWIS. *Am. Dyestuff Reptr.* **19**, 686–8(1930).—The spectrograph is a means for analyzing materials in 3 senses: general analysis such as can be readily detected by chem. means; the detection of traces of elements in complex material in cases where chem. analysis is difficult or impossible; the simultaneous ready recognition of the unsuspected element along with those which are familiar. MILTON HARRIS

Kinds and causes of odors in textiles. GEO. RICE. *Textile Colorist* **52**, 454, 486 (1930).—A discussion of the many causes of unpleasant odors in woolen textiles. R. K. WORNER

Röntgen rays in fiber research. H. MARK. *Kunstseide* **12**, 214–20(1930); *Jentgen's Rayon Review* **2**, 196 202(1930).—A review of the development of the application of x-ray analysis to fibrous materials, giving diagrams for ramie, flax, cotton cellulose, mercerized cellulose, viscose and cellulose acetate rayons. The applications of x-rays in this connection are discussed under 3 headings: analytical differentiation of various types of fibers, detn. of fiber properties and structure analysis. FREDERICK C. HAHN

"Bontaka" fiber from Madagascar: its value as a textile and as a paper-making material. F. HEIM DE BALSAC, G. S. DAGAND, H. HEIM DE BALSAC, L. LEFÈVRE, A. PARVEAUD AND O. ROERICH. *Bull. agence gén. colonies* **23**, 600–16(1930).—The anatomo-histological characteristics of the stem and fibers are described. Bontaka tow is constituted of beautiful cellulosic fibers of remarkable length, strength and even flexibility; but it is of no value as a textile on account of the anatomical arrangement of the fibers, because even mild chem. treatment liberates the ultimate fibers, while mech treatment such as carding results in irregular tearing of the parenchyma which holds the fibers together. The compn. of the tow on the dry basis (H_2O 8.71%) was ash 2.46, fats and waxes 0.70, cellulose 53.40%. The compn. of the ash was: MnO_2 12.54, Fe_2O_3 6.12, CaO 64.63, MgO 13.00, SiO_2 2.90, SO_3 0.81%. The lignin is very difficult to eliminate by means of Br and NaOH, 6 treatments being required for proper isolation of the cellulose. Bontaka cellulose contains 89% of normal (or cotton) cellulose; the lignin contains 39% of pentosans (calcd. as pentoses) together with traces of hexosans and some methoxylated complexes. The dimensions of the elementary fibers are: av. length about 50 mm., diam. 0.025–0.060 mm. (av. 0.035), diam. of lumen from practically nonexistent to 0.015 mm.; they are rather stiff, strong and elastic. Cooking the tow 8 hrs. under a pressure of 3 kg. with a 6° Bé. NaOH soln. (42 g. per l.) yielded 56% of light brown, air-dry pulp, which bleached very easily with NaOCl, and gave white sheets which were rough to the touch, had little rattle and possessed very high tensile strength, folding endurance and tearing resistance. The great length of the fibers, however, rendered the prepn. of hand-made sheets very difficult and would make the stock very difficult to handle on the paper machine. A.P.-C.

Hibiscus fibers from India and Iraq. ANON. *Bull. Imp. Inst.* **28**, 284–9(1930).—A sample of *H. sabdariffa* var. *altissima* resembled both jute and *H. cannabinus* in general character and contained about the same amt. of cellulose. Five samples of *H. cannabinus*, all grown on the Rustam Exptl. Farm, Iraq, consisted of 4 of Deccan hemp of the Indian red-stemmed variety and 1 of a local strain cultivated in certain regions of Iraq. The first 4 were of saleable quality, the most valuable being 2 that were cut during the flowering period, while the local strain sample was considerably inferior and might not be worth shipment. A. PAPINEAU-COUTURE

The technic of the bleaching of flax. E. DUTOIT. *Tiba* **8**, 673–7, 799–805, 917–28,

1047–51, 1161–7(1930).—A detailed discussion of the different methods of bleaching flax under various conditions. A. PAPINEAU-COUTURE

The value of textile-testing instruments for white and colored fabrics. H. D. MARTIN. *Textile Colorist* **52**, 455–6, 487(1930).—Attention is called to methods and app. for testing shrinkage, heat transmission, air permeability, fading, weather effects, launderability, "fatigue," etc. R. K. WORNER

The absorption of tannic acid by cellulose acetate silk. P. E. KING AND A. R. SAHASRANAM. *J. Soc. Dyers Colourists* **46**, 118–21(1930).—The absorption power of acetate and viscose rayons for tannic acid in various strengths and in different times is compared. Results, in figures and graphs, indicate that cellulose acetate absorbs about $^1/_6$ of the tannic acid in a given soln. The difference in % of absorption between 1 hr., 2 hrs. and overnight soaking is relatively slight (2% in 50% soln.). Viscose rayon absorbs slightly less than $^1/_2$ of the tannic acid in strengths up to a 14% soln., approaching closer to $^1/_3$ thereafter up to a 50% soln. The differences in absorption between 2-hr. and overnight soaking were about 1% (from 50% soln.). Tannin-mordanted cellulose acetate shows differences in action with basic dyes, some dyeing and others not (malachite green shows no difference with increased amts. of tannic acid or of dye). A. K. JOHNSON

Preparation of artificial silk and cotton unions for printing. J. R. HANNAY. *J. Soc. Dyers Colourists* **46**, 337–9(1930).—The most difficult problem of the printer is to obtain a satisfactory white. Artificial silk can be obtained in a satisfactory state by a simple soap scour but the cotton warp cannot be readily whitened if a long boil is ruled out. Good whites are obtained by bleaching but unfortunately the bleach so thins the handle that it is not easy to obtain a satisfactory finish. Bleaching in the warp is too expensive an operation. MILTON HARRIS

Desizing of cotton materials. A. S. HALL. *Textile Exporter* **3**, No. 36, 28–9 (1930).—A discussion and comparison of the advantages of enzyme products and *activin* in desizing. CHAS. E. MULLIN

The mildew problem with cotton and wool materials. A. J. HALL. *Am. Dyestuff Reptr.* **19**, 663–7(1930).—The nature and causes of mildew are discussed. Shirlan (aniline + salicylic acid ⟶ salicylanilide) is considered the most satisfactory antiseptic now and should eventually displace $ZnCl_2$, which for so many years has been used and considered the safest antiseptic to employ. Among the advantages which it possesses are its lack of volatility, its inertness to heat and metals, its absence of odor and color, and the fact that it does not react with cotton or a large no. of such dyes as are usually applied to this fiber. II. *Ibid* 717–9.—Microörganisms usually flourish most satisfactorily under moist conditions. The formation of color stains by action of bacteria on wool does not always indicate attack of the wool substance but may indicate a change in dyeing properties. Mildew troubles due to mold fungi are more important than those due to bacteria. Mold fungi flourish under slightly acid conditions. MILTON HARRIS

The wool dyer's violets. G. RAEMAN. *Dyer Calico Printer* **64**, 216–7, 267–9, 329–30, 391–2, 453–4, 529(1930).—A review of the violets available for dyeing wool, including a brief discussion of their chemical, dyeing and fastness properties, recipes for applying them and some historical notes of interest. R. K. WORNER

Protection of the workmen and of the neighborhood in the fur industry from the chemical standpoint. E. LOHMANN. *Zentralbl. Gewerbehyg. Unfallverh.* **17**, 99–106 (1930); *Chimie & industrie* **24**, 586–7.—A discussion of the various operations carried out in the treatment of furs, indicating the chem. hazards and the means of preventing or overcoming them. A. PAPINEAU-COUTURE

Eczema caused by dyeing with ice reds. L. R. MAYER. *Arch. Gewerbepath. Gewerbehyg.* **1**, 408–14(1930); *Chimie & industrie* **24**, 586.—By studying 4 cases of acute eczema which affected part of the operators of a plant which dyed with ice reds M. found that it depended on hypersensitiveness of the affected persons to free diazonium bases and to a substance which is formed when the N base is combined with a naphthol compd. This hypersensitiveness can also extend to other cases where it seems likely that the toxic agent is the free diazonium base. The precautions which should be taken to prevent these cutaneous affections consist in the use of rubber gloves, covering the hands and arms with lanolin, and the neutralization of alkalies on the skin whenever the latter comes in contact with alk. liquors. A. PAPINEAU-COUTURE

Fire-resisting rayon goods. FRED. GROVE-PALMER. *Am. Dyestuff Reptr.* **19**, 715–6(1930).—The old method consists of 10% Na phosphate, 2% Na tungstate and $^1/_2$% NH_4Cl. For heavy cloths are used 6 lbs. of NH_4Cl, 3 lbs. NH_4 phosphate in 6

gallons of water. For fireproofing and waterproofing, Na phosphate followed by a 5% soln. Al acetate is used. MILTON HARRIS

First-aid fire extinguishing for dyeworks. J. W. BLACKMAN. *Dyer, Calico Printer* 64, 351(1930).—A brief description of the 3 usual types of hand-operated chem. fire extinguishers, namely, the soda-acid, the foam and the CCl_4. R. K. WORNER

Fighting fires in dyeworks. WILFRID EVANS. *Dyer, Calico Printer* 64, 347 (1930).—The use of foam is advocated. R. K. WORNER

Analytical methods for textile soaps (LEVITT) 27. $MgSO_4$ from waste of artificial-silk factories, etc. (Brit. pat. 331,648) 18. Condensation products of china wood oil and phenol (U. S. pat. 1,779,345) 26. Apparatus for deodorizing hair, feathers, etc., with ozone (Brit. pat. 331,845) 1.

Dyes. I. G. FARBENIND. A.-G. Brit. 331,697, July 10, 1929. Halogen derivs. of *N*-dihydro-1,2,2′,1′-anthraquinoneazines are purified by treatment in H_2SO_4 soln. with MnO_2 or other Mn oxides higher than MnO. Production and purification may be carried out in a combined operation. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 331,247, March 21, 1929. Azo dyes are made in substance or on the fiber or other suitable substratum by coupling any diazo-, tetrazo-, or diazo-azo compd. free from sulfonic or carboxylic groups, with a 2-(2′-hydroxy-3′-naphthoylamino)-5-halo-1,4-dimethoxybenzene. Several examples are given of dyes giving orange-brown and various red shades.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 332,208, Jan. 15, 1929. Azo dyes insol. in water are made in substance, on the fiber or on a substratum, by coupling a diazotized *o*-aminobenzophenone or a deriv. of the latter contg. no sulfo, carboxy or nitro group, with a coupling component such as an arylide of 2,3-hydroxynaphthoic acid or diacetoacetic arylides. The products are fast to bucking, Cl and light. Several examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 332,319, May 3, 1930. A diazo-, tetrazo- or diazo-azo compd. is coupled with a 4-(2′-hydroxy-3′-naphthoylamino)-diphenylamine in substance or on a substratum. Dyes thus formed from tetrazodianisidine when treated with Cu compds. are faster than similar dyes from other arylides. Several examples are given.

Metal compounds of azo dyes. FRITZ STRAUB, JOSEPH GYR and OTTO KAISER (to Soc. anon. pour l'ind chim. à Bâle). U. S. 1,779,298, Oct. 21. Numerous examples are given of the production of complex metal (such as Cu, Cr, Co or Ni) compds. of azo dyes contg. cyanuric nuclei by condensing cyanuric halides with compds. which have reactive H atoms attached to O, S or N, at least one of such compds. being a complex metal compd. of an azo dye, *e. g.*, the Cu compd. of the monoazo dye from diazotized 4-sulfo-6-amino-1-phenol-2-carboxylic acid and α-naphthylamine and similar metal compds. may be used as components with aniline and the like, producing products of various colors.

Disazo dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD., R. BRIGHTMAN and W. L. B. WELLACOTT. Brit. 331,839, March 5, 1929. Disazo dyes suitable for dyeing regenerated cellulose rayon even shades are made by (1) tetrazotizing 3,3′-diaminodiphenylurea or substitution products other than hydroxy, carboxy or sulfonic derivs. and coupling with a sulfonic or carboxylic acid of a phenol or a naphthol and a 1,8-dihydroxynaphthalenesulfonic acid or an *N*-substituted deriv. in equimol. proportions; or, (2) by treating with phosgene equimol. proportions of the dyes obtained by (*a*) coupling diazotized *m*-nitroaniline or *m*-aminoacetanilide or substitution products other than hydroxy carboxy and sulfonic derivs., with a carboxylic or sulfonic acid or a phenol or a naphthol and reducing or hydrolyzing, or (*b*) coupling the same diazo components as in (*a*) with a 1,8-dihydroxynaphthalenesulfonic acid or a 2,8,6-acid or a *N*-substituted deriv. of the latter and reducing or hydrolyzing. Several examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Brit. 331,842, March 9, 1929. Aryl ethers of leuco compds. of vat dyes are obtained by heating the leuco compds. or the vat dyes themselves in the presence of reducing agents such as metals, with alkali phenolates, preferably in an inert solvent or excess of phenol. Examples are given of the treatment of pyranthrone and of flavanthrone, the metal used being Zn, Cu or Fe. The products may also be obtained from intermediate compds. which are convertible into hydro compds. of the vat dyes under the conditions employed. The products obtained may be used as *dye intermediates*, for effecting purification of dyes, and in some cases for dyeing directly.

Vat dyes. PAUL NAWIASKY and ARTUR KRAUSE (to General Aniline Works). U. S. 1,780,836, Nov. 4. See Ger. 485,790 (*C. A.* **24**, 1989).

Vat dyes of the anthraquinone series. WALTER MIEG (to General Aniline Works). U. S. 1,781,238, Nov. 11. Vat dyes dyeing cotton in the vat from reddish gray to olive-brown shades are prepd. by acting with a condensing agent of an acid character such as concd. H_2SO_4, chlorosulfonic acid and a mixt. of 3–5 parts of $AlCl_3$ and 1 part of NaCl or 3–25 parts of pyridine on a dianthraquinonylamine contg. an acridone ring which is substituted by at least one halogen atom and contg. at least one acylamino group. The condensation is carried out at a temp. of about 10–40° and higher when the condensation is effected by means of H_2SO_4 or chlorosulfonic acid and at 130–160° and higher when a mixt. of $AlCl_3$ and NaCl or pyridine is used as condensing agent. Examples are given, in which, as starting materials, there are employed the dianthraquinonylamine deriv. obtained by the condensation of equimol. proportions of trichloroanthraquinoneacridone, and the amino compd. obtained by the reduction of a nitrated chloroanthraquinoneacridone.

Vat dyes of the anthraquinone series. I. G. FARBENIND. A.-G. Brit. 331,620, April 30, 1929. Yellowish brown dyes are formed by the action on a β-mercaptan compd. of the anthracene series such as 2-mercaptoanthracene with an anthraquinone-2-carboxylic acid such as 1-chloroanthraquinone-2-carboxylic acid, substituted in the 1-position by halogen or a nitro or diazo group, and treating the anthrylthioanthraquinone-2-carboxylic acid obtained with an acid condensing agent to form the corresponding thioxanthone compd. Mercaptoanthracenes are made by reducing the corresponding mercaptoanthraquinones and the latter are obtained by reduction of the corresponding disulfonyl chlorides of anthraquinone.

Acid dyes of the phenonaphthosafranine series. PAUL LAEUGER (to the firm J. R. Geigy S. A.). U. S. 1,779,279, Oct. 21. Dyes giving good blue tints fast to light and alkalies are obtained by the further sulfonation of safranine-16-monosulfonic acids such as those which may be made from the corresponding isorosinduline-6-sulfonic acids by exchanging the 6-sulfo group for an unsym. *N*-alkylated *p*-phenylenediaminesulfonic acid, in which the *o*-position to the free amino group is occupied by the sulfo group. Various details are given for the manuf. of the safranine-16-monosulfonic acids from starting materials such as 6-sulfo-3-ethylbenzylisorosinduline, 6-sulfo-3-methylbenzylisorosinduline, 6-sulfo-3-ethylphenylisorosinduline, 6-sulfo-3-methylphenylisorosinduline or any other isorosinduline-6-sulfonic acid, with 1-methyl-2-ethylamino-5-aminobenzene-4-sulfonic acid preferably used in form the sodium salt or 1-methyl-2-methylamino-5-aminobenzene-4-sulfonic acid, 1-ethylbenzylamino-4-aminobenzene-3-sulfonic acid, 1-diethylanimo-4-aminobenzene-3-sulfonic acid or any other unsym. *N*-alkylated *p*-phenylenediaminesulfonic acid having its *o*-position to the free amino group occupied by the sulfo-group.

Acid wool dyes. I. G. FARBENIND. A.-G. Brit. 331,217, March 25, 1929. Compds. such as 1-diazo-4-bromoanthraquinone-2-sulfonic acid or the diazo compd. of 1-amino-4-phenylaminoanthraquinone-2-sulfonic acid are treated with amines such as aniline, hexahydroaniline and monoethylaniline, first forming diazoamino compds. which decompose with evolution of N into substances in which the 1- or the 4-position or both of the anthraquinone nucleus are occupied by the substituted amino group. Catalysts such as Cu, Zn, Mg or their compds. and inert diluents such as C_6H_6 or $PhNO_2$ may be used. Examples are given. Cf. *C. A.* **24**, 4941.

Acid wool dyes. I. G. FARBENIND. A.-G. Brit. 332,203, April 15, 1929. A 1-amino-4-haloanthraquinone-2-sulfonic acid is condensed with an aminonitrile of the benzene series, *e. g.*, *m*-aminobenzonitrile (which with 1-amino-4-bromoanthraquinone-2-sulfonic acid in the presence of soda and Cu_2Cl_2 gives a reddish blue dye). The 1-amino-3-cyano-4-(and 5)-methylbenzenes give greener dyes.

"Amplifying" aniline dyes. MARY B. PARRISH. U. S. 1,780,981, Nov. 11. An aniline dye is "predigested" in the presence of pancreatin, ox gall, NaCl, citric acid, HOAc and acetone and the resulting mass is boiled with a mixt. of soap and tinctures of vegetable fixatives including camomile flowers, hyssop, ground cedar wood and myrrh and the mass is permitted to cool to "blood heat" and is then "redigested" by adding pancreatin, gelatin, acetone, ox gall, NaCl and HOAc at "blood heat" and the resulting product is permitted to "ferment" in a warm room for about 2 weeks, then mixed with dextrin and the mixt. is baked at "bread baking temp." until a product of crisp consistency is obtained, which is suitable for dyeing when redissolved in water.

Anthraquinone dyes. IMPERIAL CHEMICAL INDUSTRIES, LTD., A. SHEPHERDSON and W. W. TATUM. Brit. 331,952, April 22, 1929. Anthraquinone dyes are formed by condensing a 4-halo-1-aminoanthraquinone-2-sulfonic acid with a *p*-diamine in the

presence of a Cu oxide catalyst. A dye giving level greenish shades on wool is obtained by boiling Na 4-bromo-1-aminoanthraquinone-2-sulfonate with *p*-phenylenediamine, Na_2CO_3, water and Cu oxide, and pptg. the dye with HOAc.

Sulfide dyes. MAX WYLER (to Imperial Chemical Industries, Ltd.). U. S. 1,779,508, Oct. 28. Nitroaceto-*p*-xylidide is heated with 2 or more mol. proportions of benzidine and with S, to form a dye which dyes cotton orange shades from a sulfide bath.

Dye compositions. W. KRITCHEVSKY, H. C. PRUTSMAN and E. MORRILL. Brit. 331,491, Dec. 31, 1928. Dye compns. suitable for home use comprise a sol. dye and an alkylated naphthalenesulfonic acid or salt of such an acid, and there may also be added various assistants such as mordants, fillers, penetrators, diluents or solvents, various examples of which are given. Cf. *C. A.* 24, 2612.

Reddish derivative of flavanthrone. BIRKETT WYLAM, JOHN E. G. HARRIS and JOHN THOMAS (to Scottish Dyes, Ltd.). U. S. 1,779,791, Oct. 28. Leucoflavanthrone is treated, at a temp. of 50° or higher (suitably about 60°) and in the presence of a tertiary org. base such as pyridine with a reagent such as an alkylsulfuric acid halide, *e. g.*, methylsulfuric acid chloride, and the melt is extd. with a dil. alkali such as Na_2CO_3. The product dyes cotton and wool scarlet from a slightly alk. bath, changing to yellow with acid oxidizing agents.

Dyes and intermediates. I. G. FARBENIND. A.-G. Brit. 331,269, March 26, 1929. A 1,9-pyrazoleanthrone,1,9-thiazoleanthrone or 1,9-anthrapyrimidone contg. a methyl group in the 2-position is treated with an alk. condensing agent such as caustic alkali in water or alc.; the 2-methyl group appears to be attacked and products are formed in which 2 mols. of starting material are linked through an ethylenic linkage —CH : CH— and which may serve as *dyes* or *intermediates*. Several examples are given.

Dyes and intermediates. I. G. FARBENIND. A.-G. Brit. 332,316, May 1, 1929. A 1-haloanthraquinone-2-carboxylic acid is treated with hydrazine (preferably in the presence of a diluent such as pyridine) and the pyrazoleanthrone-2-carboxylic acid thus obtained is converted to the acid chloride and condensed with an aromatic hydrocarbon or halogen deriv. of such a hydrocarbon to produce 2-aroylpyrazoleanthrones, and alkylation or aralkylation on the N atoms of the pyrazole ring may be effected. The products contg. a free imino group in the pyrazole ring and a halogen atom in the aryl residue *o*- to the keto group may be converted into vat dyes by treatment with acid-binding agents such as KOAc or Na_2CO_3.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 331,597, April 10, 1929. β-Naphthylaminophenoxyaliphatic acids are obtained by treating a β-naphthol or β-naphthylamine or substitution product of either with a sulfite and a 3- or 4-aminophenoxyaliphatic acid or deriv. Several examples are given of the production of intermediates in this manner and of their use in manuf. of azo dyes with other components.

Dye intermediates. I. G. FARBENIND. A.-G. Brit. 332,192, March 15, 1929. 5,8-Dihalo-1,2-benzanthraquinones are prepd. from 2-α-naphthoyl-3,6-dihalobenzoic acids by treatment with non-sulfonating acid condensing agents such as H_3PO_4, P_2O_5, $ZnCl_2$ or $AlCl_3$. $PhNO_2$ may be used as a vehicle. The prepn. of the 5,8-dichloro and 5,8-dibromo derivs. is described. It is stated that if H_2SO_4 is used as condensing agent a 5,8-dichloro-1,2-benzanthraquinonesulfonic acid is obtained, and by acting on a 2-α-naphthoyltetrahalobenzoic acid, sulfonation without ring closure occurs.

Dye intermediates. IMPERIAL CHEMICAL INDUSTRIES, LTD., and M. WYLER. Brit. 331,687, June 27, 1929. Aminoxylenol and its *N*-acyl derivs. are formed by nitrating 1,3-dimethyl-2-acylaminobenzene, reducing, diazotizing and converting into the hydroxy compd. An example is given of the use of 1,3-dimethyl-2-acetylaminobenzene as starting material.

Dye intermediates (anthraquinone derivatives). R. J. LOVELUCK, E. G. BECKETT, J. THOMAS and SCOTTISH DYES, LTD. Brit. 331,537, Dec. 28, 1928. Products formed by oxidizing an *o*-amino-β-sulfonic acid of anthraquinone with $K_2S_2O_8$ in H_2SO_4 are treated with a halogenating agent such as $NaClO_3$ and HCl to replace the sulfonic group by halogen, and on reduction with Na hydrosulfide or H_2S and NH_3 or neutral hydrosulfite the corresponding *o*-aminohalogen derivs. are formed. Various examples are given.

Dye intermediates from halobenzoylbenzoic acids. JOHN THOMAS and HUGH A. E. DRESCHER (to Scottish Dyes Ltd.). U. S. 1,779,221, Oct. 21. In the production of compds. such as 4'-(sulfo)-2-benzoylbenzoic acid, a (4'-halo)-2-benzoylbenzoic acid is treated with a sol. sulfite such as Na_2SO_3 in aq. soln. at a temp. of about 180° and under a corresponding pressure. A Cu salt promotes the reaction. The process is not restricted to halobenzoylbenzoic acids in which the halogen is attached to the

benzene nucleus not contg. the carboxylic acid substituent, but can be applied to halo-2-benzoylbenzoic acids and their derivs. generally, including those contg. halogen in the benzene nucleus to which is attached also the carboxylic acid substituent such as halogenated benzoyl-*o*-benzoic acids, which are made by condensing halogenated phthalic anhydride with benzene and its derivs. The 4'-(sulfo)-2-benzoylbenzoic acid can be converted, by condensing agents such as H_2SO_4, into the anthraquinonesulfonic acid.

Condensation products of the benzodiazine series. WINFRID HENTRICH, MAX HARDTMANN and RUDOLF KNOCHE (to General Aniline Works). U. S. 1,780,879, Nov. 4. Compds. such as 2,4-di(4'-hydroxynaphthyl)quinazoline, 4-(4'-hydroxynaphthyl)-quinazoline and 4(4'-methoxyphenyl)quinazoline are produced by reaction in the presence of $AlCl_3$ between a halobenzodiazine contg. at least one halogen atom in the diazine nucleus such as 2,4-dichloroquinazoline or 4-chloroquinazoline and an aromatic phenolic compd. such as 1-hydroxynaphthalene, or by causing suitable aromatic Mg halide compds., *e. g.*, alkoxyphenyl Mg bromide, in ethereal soln. to react upon halogenated benzodiazine contg. the halogen in the diazine nucleus. The products are generally high-melting or infusible yellowish powders which are insol. in water, sol. in org. solvents with a yellowish coloration. They may be used as *intermediate products in the manuf. of dyes.* Cf. *C. A.* **24**, 3381.

Stable diazo compounds. I. G. FARBENIND. A.-G. Brit. 332,227, April 16, 1929. Diazonium salts of complex metallic fluoric acids are made by causing complex acids such as Ti, Al, Sn and Sb hexafluoric acids or their salts to react with a diazonium compd. such as tetrazotized dianisidine or diazotized 4-aminoazobenzene or *m*-nitro-aniline. The products may be used in *dyeing* and *printing* and in *combating insect pests.*

Sulfonyl chlorides. I. G. FARBENIND. A.-G. Brit. 331,596, April 10, 1929. Aromatic amino sulfonyl chlorides and their nuclear substitution products, suitable for use as *dye intermediates*, synthesis of *pharmaceutical products*, manuf. of auxiliary compns. for use *in dyeing*, and as *insecticides*, are made by causing chloro sulfonic acid to act on an aromatic primary aminosulfonic acid or a nuclear substitution product. Examples are given of the treatment of 4-chloroaniline-3-sulfonic acid, 2,5-dichloroaniline-4-sulfonic acid, 4,5-dichloroaniline-4-sulfonic acid, 4-amino-1-methylbenzene-3-sulfonic acid, 2-chloro-4-amino-1-methylbenzene-5-sulfonic acid, 3-chloro-2-amino-1-methyl-benzene-5-sulfonic acid, 1,3-dimethyl-4-aminobenzene-5-sulfonic acid, 1,3-phenylenedi-amine-4,6-disulfonic acid, 1-amino-3-hydroxybenzene-6-sulfonic acid, 1-naphthyl-amine-7-sulfonic acid, aniline-*o*-sulfonic acid and similar starting materials to produce the corresponding sulfonyl chlorides.

Dyeing animal fibers. J. S. WILSON, L. J. HOOLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 332,232, Jan. 16, 1929. Materials such as wool or silk are dyed or printed by means of sulfonic acids of vat dyes (which are applied by a vatting process) such as those of the anthraquinone, indigo and arylidoquinone series. Protecting agents such as cresol, phthalic anhydride, "Protectol," sulfite cellulose liquor or assistants such as "Dispersol" or "Nekal A" may be used and various details, examples and modifications of procedure are described. Dye prepns. such as those prepd. as described in Brit. 332,249 may be used.

Dyes. J. S. WILSON, L. J. HOOLEY, J. THOMAS and SCOTTISH DYES, LTD. Brit. 332,249, Jan. 16, 1929. Sulfonic acids of vat dyes suitable for dyeing animal fibers by the process described in Brit. 332,232 (preceding abstr.) are made by replacing the halogen in halogenated vat dyes by the sulfonic group, through the action of sulfites, as by treating 3,3'-dichloroflavanthrone, Caledon Orange 4R, Caledon Orange RRK, 3,3'-dichlorodianthraquinonedihydroazine or the like with phenol and Na_2SO_3, in finely divided aq. suspension.

Dyeing and printing with vat dyes. PHILIPPE BRANDT and KARL GLENZ (to Durand & Huguenin S. A.). U. S. 1,779,305, Oct. 21. An ester salt of a leuco vat dye, a suitable oxidizing agent such as $NaClO_3$ and a substance capable of forming acid when heated are applied to the goods, followed by steaming, in the presence of an aromatic amino compd. contg. a neg. salt-forming group, such as Na sulfanilate. Cf. *C. A.* **24**, 1749.

Dyeing various textile materials. BRITISH CELANESE, LTD., and W. I. TAYLOR. Brit. 332,290, Jan. 11, 1929. In producing intermittently colored, multi-colored or cross-dyed effects on filaments, yarns or other forms of textile materials such as cotton, silk, wool or various artificial silks, a mech. reserve (such as a melted mixt. of refined peanut oil and hardened whale oil) is applied at intervals to the material while in motion. Various details and auxiliary treatments are described.

Dyeing and printing wool. I. G. FARBENIND. A.-G. Brit. 332,202, April 15, 1929. Wool is dyed with a monoazo dye obtained by coupling diazotized 4-nitro-1-amino-

benzene-2-sulfonic acid with a sulfonic acid of β-amino- or an *N*-alkyl-β-aminonaphthalene and discharge printed in a usual manner.

Dyeing filaments, yarns, straws, ribbons, etc., of extruded cellulose acetate or other cellulose esters and ethers. BRITISH CELANESE, LTD., and W. I. TAYLOR. Brit. 332,263, Jan. 11, 1929. Intermittently colored, multi-colored or cross-dyed effects on subsequent dyeing are obtained by applying a saponifying agent at intervals along the length of the material while it is in motion, preferably continuously with production, for which purpose various alkali solns. may be used. App. and various details of procedure are described.

Dyeing organic derivatives of cellulose. GEORGE RIVAT, ERNEST CADGENE and CAMILLE DREYFUS (to Celanese Corp. of America) U. S. 1,779,494, Oct. 28. Materials such as mixed fabrics contg. cellulose acetate are treated with a concd. soln. of a ferric salt such as $FeCl_3$ in order to prepare them for dyeing with logwood or the like.

Dyeing regenerated cellulose materials. IMPERIAL CHEMICAL INDUSTRIES, LTD., and R. BRIGHTMAN. Brit. 331,822, April 5, 1929. Dyeing in level shades is effected by use of dyes obtainable by coupling a tetrazotized mono- or di-sulfonic acid of 4,4'-diaminodiphenylurea with 2 mols. of a sulfonic, or carboxylic, acid deriv. of a phenol, naphthol, naphthylamine or *N*-substituted naphthylamine or with 1 mol. of such a component and 1 mol. of an aminonaphtholsulfonic acid or an *N*-substituted deriv. (similar dyes being also obtainable by other processes). Numerous examples are given. Cf. *C. A.* **24**, 5510.

Mordanting and dyeing cellulose HENRY DREYFUS. U. S. 1,779,464, Oct. 28. Materials such as cellulose acetate are treated with solns. of aliphatic acid salts of mordant metals such as Al acetate, lactate or acetolactate.

Dyeing "viscose silk." I. G. FARBENIND. A.-G. Brit. 331,612, April 22, 1929. The dyeing properties of "viscose silk" are improved by treating the freshly finished material, while still wet, with ammoniacal Cu oxide solns. free from caustic alkali and contg. up to 0.3% Cu, until a small percentage of the dry wt. of the material has dissolved. Various details and examples of procedure are given.

Coloring for fabrics such as silk. ANTON PICAREFF (to Anton Picareff Art Studios, Inc.). U. S. 1,780,314, Nov. 4. An aq. coloring soln. is formed from a basic dye, together with gum acacia and tannic acid.

Dyeing pelts, hairs, feathers, etc. PAUL VIRCK (to General Aniline Works). U. S. 1,778,819, Oct. 21. The material is treated with an aq. soln. of 2-(3'-aminophenylamino)naphthalene-HCl and with an acid nitrite soln. (producing a dyeing "between rose and yellow") or other similar naphthalene derivs. may be used which contain as a substituent a 3-aminoarylamino group of the benzene series. 2-(4'-Methyl-3'-aminophenylamino)naphthalene produces a similar dyeing and 2'-(4-methyl-3-aminophenylamino)-7-hydroxynaphthalene produces a reddish brown dyeing. Similar dyeings are obtained from corresponding naphthalene derivs. substituted in the benzene nucleus by halogen. Cf. *C. A.* **24**, 5167.

Decolorizing dyed fabrics. W. KRITCHEVSKY. Brit. 331,194, Dec. 22, 1928. A mixt. is used which is formed of (*a*) a sulfoxylate formaldehyde salt or a hyposulfite or Zn dust, (*b*) a solid acid or salt of acid reaction such as tartaric acid or $NaHSO_3$, and (*c*) a small quantity of Na isopropylnaphthalenesulfonate or similar compd. The mixt. may be supplied in small packages in dry form, and dissolved at the time of use.

Apparatus for dyeing, bleaching or other treatments of loose yarns or bobbins. F. G. SCHUMACHER and J. J. MÜLLER. Brit. 331,706, July 20, 1929. Structural features.

Apparatus for dyeing tubular textile webs with their ends sewn together in endless formation. H. LOESER. Brit. 332,180, Jan. 5, 1929. Structural features.

Apparatus for washing, dyeing or other liquid treatments of cakes of artificial filaments in a rotatable box. HORACE J. HEGAN and EDWARD HAZELEY (to Courtaulds Ltd.). U. S. 1,779,313, Oct. 21. Structural features.

Vat and associated apparatus for washing or other liquid treatments of lengths of fabric. FLORENT HINNEKENS (to Van Vlaanderen Machine Co.). U. S. 1,781,391, Nov. 11. Structural features.

Dye vat with a liquor-circulating propeller. C. F. KRANEY and HEINZE MASCHINENFABRIK A.-G. Brit. 331,520, Dec. 28, 1928. Structural features of an app. in which freely floating pieces of material are moved in alternate directions in the liquor.

Roller and vat apparatus for dyeing fabrics. HANS NABHOLZ. U. S. 1,780,628, Nov. 4. Structural features.

Preparing fabrics containing wool for dyeing. DEUTSCHE WOLLENWAREN MANUFAKTUR A.-G. Brit. 331,529, March 21, 1929. The process described in Brit. 308,605

(*C. A.* **24**, 511) is modified by applying the treatment with solvents to the materials previous to weaving them.

Ventilating system for dye-houses, etc. HALL & KAY, LTD., H. KAY, J. H. HALL and P. KAY. Brit. 332,387, July 6, 1929.

Finishing yarns or fabrics. FRANCIS J. STOKES. U. S. 1,779,831, Oct. 28. Air is removed from the material in the standard form of package in which it is produced, such as cops, cones, bobbins or spools, the material is treated in a vacuum, with liquid such as dye or other soln., the pressure is raised at least to atm. pressure and the material is sepd. from surplus liquid and is centrifuged while treated with additional liquor such as dye soln. or water.

Use of ethylene chloride for degreasing textile materials. WILHELM PFAFFENDORF (to General Aniline Works). U. S. 1,780,885, Nov. 4.

Bleaching and stripping textile materials. BRITISH RESEARCH ASSOCIATION FOR THE WOOLEN & WORSTED INDUSTRIES and A. T. KING. Brit. 332,389, July 6, 1929. In bleaching and stripping of dyes there is used a mixt. of $NaHSO_3$ or $KHSO_3$ and Na_2SO_3 or K_2SO_3 contg. about 2 mol. proportions of bisulfite to each mol. proportion of normal sulfite, such that when the soln. is dild. to 2% SO_2 it has a p_H of about 6.8. Strong solns. of this character produce a glossy effect and fiber damage is minimized by satg. the soln. with NaCl or Na_2SO_4.

Hypochlorite composition for bleaching. LLOYD T. HOWELLS (to Elec. Smelting & Aluminum Co.). U. S. 1,779,274, Oct. 21. A compn. suitable for bleaching textile materials is formed from a sol. fluosilicate such as that of Na and a hypochlorite compd. such as NaOCl.

Preventing shrinking of wool. LEIGHTON B. SMITH and CHARLES E. RUBY. U. S. 1,781,415, Nov. 11. An alk. soln. for treating wool comprises an alkali metal hypochlorite and a salt of a weak acid and a strong base such as $NaHCO_3$ which serves as a buffer electrolyte.

Brocade effects on fabrics comprising cellulose acetate. CAMILLE DREYFUS and WM. R. BLUME (to Celanese Corp. of America). U. S. 1,780,645, Nov. 4. The fabric is locally delustered, a paste is then applied comprising cellulose nitrate, a softening agent, a pigment and a solvent for the cellulose nitrate which is a non-solvent for the cellulose acetate (such as alc. and ether) and the fabric is then subjected to a relustering treatment. Other similar treatments involving other cellulose derivs. are described.

Moiré scratch patterns in cellulose acetate fabrics. ALEXANDER MILHOMME (to Progressive Silk Finishing Co.). U. S. 1,781,296, Nov. 11. A pattern is scratched on the fabric while in folded moistened condition, and the fabric is then dried and subjected to heat and pressure.

Relustering artificial silk, etc. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 332,231, Jan. 5, 1929. Textile materials comprising various cellulose esters or ethers have their luster increased or restored, or are protected from the action of delustering agents such as hot aq. media, by treatment with substantially dry steam. Various details and examples are given.

Apparatus for treating artificial silk or wool tufts, etc., with liquids for washing or other purposes. SNIA-VISCOSA. Brit. 332,003, May 27, 1929. Structural features.

Woven bag fabrics, etc., made of coco fiber yarns. R. G. H. VAN DER JAGT. Brit. 332,136, Oct. 6, 1928. Various details of manuf. are described.

Apparatus for steaming and drying fabrics, etc. HERMANN MALY. U. S. 1,778,863, Oct. 21. Structural features.

Treating waste spun or woven artificial silk materials. ADOLPH L. BURLIN. U. S. 1,781,317, Nov. 11. See Brit. 322,608 (*C. A.* **24**, 2899).

Preparing animal hair for felting. RICHARD HAYNN (to General Aniline Works). U. S. 1,779,363, Oct. 21. Before felting, the hair is treated with a F compd. such as K bifluoride which serves to improve the felting properties.

Dry-cleaning fabrics. LLOYD E. JACKSON. U. S. 1,778,948, Oct. 21. In a process with repeated application of soap-bearing naphtha, the detergent power of the used naphtha is restored by testing quantitatively for free acid and for water and adding alkali and water in sufficient quantities to restore the material to approx. its original condition.

Coatings for fabrics, etc. V. SCHOLZ and ATLAS AGO CHEMISCHE FABRIK A.-G. Brit. 332,266, March 13, 1929. Coating compns. are prepd., either (1) by dissolving solid linoxyn in a suitable org. solvent (such as by use of alc., benzene, xylene, toluene, MeOAc, EtOAc, tetralin, C_2HCl_3 or mixts. of these, suitably with heat and pressure), mixing the resulting soln. with a turgescent or dissolved nitrocellulose or other suitable cellulose ester or ether, and removing the solvent of the nitrocellulose or like material;

or, (2) by kneading the linoxyn with the turgescent or dissolved cellulose deriv., removing the solvent and working up the product as by heat and pressure, to form a transparent solid product which may be dissolved in org. solvents. The products may be mixed with dyes, fillers, etc., and applied to fabrics by rollers, presses, etc.

Rubberizing fabrics (use of non-explosive gas mixtures in the apparatus). FIRESTONE TYRE & RUBBER CO., LTD. Brit. 331,594, Jan. 10, 1929. In an app. for passing fabric through a bath of rubber dissolved in benzene and drying it in a chamber contg. an inert gas such as CO_2 or producer gas, the proportion of producer gas to benzene is detd. by submitting streams of the producer gas and of the gaseous content of the drying chamber simultaneously to a device for comparing their thermal conductivities. Various details of app. are described.

Fungus-proof and waterproof rubber-coated fabric. FRANK A. MCDERMOTT and FOREST J. FUNK (to E. I. du Pont de Nemours & Co.). U. S. 1,779,258, Oct. 21. The fibers of a fabric such as mine ventilating tubing are impregnated with a soln. contg. not less than 1% by wt. based on the fabric of a slightly water-sol., non-volatile, heavy-metal salt of an org. acid having fungicidal properties, such as Zns alicylate or benzoate, and, after evapn. of the solvent, the fabric is then coated with rubber.

Aircraft fabric. ISADORE M. JACOBSOHN and STARR TRUSCOTT. U. S. 1,779,846, Oct. 28. A base fabric such as light-wt. cloth is coated with a compn. comprising gelatin, glycerol and rubber dissolved in C_6H_6 which is mech. spread on the fabric. U. S. 1,779,847 describes the coating of fabric with a film of cuprammonium cellulose, insolubilizing this coating by an acid coagulant, and then immersing in a glycerol bath, to render the fabric flexible and impermeable to gases. Cf. *C. A.* **24**, 2617.

Balloon fabric. KARL HUERTTLE (to Goodyear-Zeppelin Corp.). U. S. 1,779,395. Oct. 21. Pieces of gas-tight material such as goldbeater's skin are treated with a coloring substance such as a dye to increase their visibility, and subsequently united with textile material with the edges of the pieces overlapped.

Balloon fabric. WM. C. CALVERT (to Goodyear Tire & Rubber Co.). U. S. 1,779,388, Oct. 21. A fabric is provided with a plurality of coatings the inner layers of which consist essentially of rubber and the outer layers of gelatin, with an outer ply of regenerated cellulose adhering to the gelatin-contg. layers. Cf. *C. A.* **24**, 976.

Balloon fabric. CLARENCE M. CARSON (to Goodyear Tire & Rubber Co.). U. S. 1,779,389, Oct. 21. A light, closely woven fabric is coated with a mixt. of gelatin and vulcanized latex. Cf. *C. A.* **24**, 2312.

Water-soluble product from fatty acids of wool fat. ALFRED THAUSS and GUSTAV MAUTHE (to General Aniline Works). U. S. 1,780,252, Nov. 4. A product which is suitable for use in *dyeing* and *leather manuf.* is obtained by treating the fatty acids of wool fat with sulfuric acid monohydrate in the presence of a phenol such as PhOH.

Sulfonating wool fat in the presence of a phenol. GUSTAV MAUTHE and ALFRED THAUSS (to General Aniline Works). U. S. 1,780,027, Oct. 28. By treating wool fat with H_2SO_4 in the presence of a phenol such as PhOH, a cresol, a chlorophenol or a naphthol there is obtained a semi-solid friable mass, that on boiling with water forms a stable emulsion that gives a clear soln. when rendered alk.; the product may be salted out from its solns. and is suitable for use in the *textile* and *leather industries*.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Chalking (of paints). RICHARD KEMPF. *Farben-Ztg.* **36**, 20–2(1930).—The causes of chalking lie not only in the phys. and chem. changes undergone by the pigment and binder individually but also in the reactions between these 2 ingredients. G. G. S.

New fire-preventive paints. R. SCHWARZ AND K. WULF. *Farbe u. Lack* **1930**, 502.—While no paint exists that will render wood non-flammable, many do retard the burning. A method of test is given. A piece of wood is painted with the exception of one side and one end. After the paint is dry, the flame is applied to the angle between the two unpainted surfaces. The behavior of the flame on reaching the painted portions is then noted. Water glass is probably the best and cheapest fire-retardant material to use in paints. G. G. SWARD

Two new devices for testing paints. ERICH STOCK. *Farben-Ztg.* **36**, 24(1930).—A small vise made of glass blocks for use in examn. of cross sections of paint films is described. A viscometer consisting of a brass cup with a small orifice in the bottom is described. A special feature is a gate for starting and stopping the flow of the liquid G. G. SWARD

Exposure tests on white paints. KENNETH A. NAGEL. *Am. Paint J.* **15**, No. 2, 24–6(1930).—A preliminary report of paints exposed in 1930 and a summary of the condition of 17 paints exposed in various vehicles in 1929 are given. Of all the pigment combinations used, Pb carbonate gives the best appearance in raw linseed oil; but little difference in boiled oil was observed. From the standpoint of checking and chalking, boiled oils produce better films than raw oil. In general, the pigments were rated in the following order, best, lead carbonate, titanox, lithopone, zinc oxide, poorest.
G. G. SWARD

The evaluation and compilation of the methods used in accelerated testing of protective coatings. E. H. KESSLER. *Am. Paint & Varnish Mfrs' Assoc., Circ.* No. 370, 548–64; *Am. Paint J.* **14**, No. 52C, 25; *Paint, Oil & Chem. Rev.* **90**, No. 18, 14–7; *Oil, Paint & Drug Reptr.* **118**, No. 19, 63–4(1930).—A no. of replies to a questionnaire on accelerated testing (not necessarily involving light) are abstracted. Incomplete data of exposure results on 18 widely varying materials using out-of-doors exposures and 5 accelerated weathering machines are given. A bibliography is attached. G. G. S.

A study of two-coat spray painting on different woods. P. D. BUCKMINSTER. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 533–42; *Am. Paint J.* **14**, No. 52D, 26; *Paint, Oil & Chem. Rev.* 90, No. 17, 73–6; *Oil, Paint & Drug Reptr.* **118**, No. 19, 61–2(1930).—There is given a preliminary report on exposures of house paints on a fence duplicating beveled-siding house construction. Northern white pine, Sitka spruce, cypress and redwood were used in panels 8 by 6 ft. Weathering has not yet proceeded far enough for a report.
G. G. SWARD

Color control in the paint plant. M. REA PAUL AND J. P. ST. GEORGE. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 418–36; *Am. Paint J.* **14**, No. 52B, 8; *Paint, Oil & Chem. Rev.* **90**, No. 17, 63–7; *Oil, Paint & Drug Reptr.* **118**, No. 19, 54(1930).—Drifts in the spectral distribution curves of 4 representative paints are shown to take place both with paints stored in the can and with dry films. These curves may be used as guides in the restoration of the color of the paints. The av. tolerances permitted by 200 consumers in a series of grays ranged from 1 to 6.5% for grays of brightness of 7.5 to 40%, resp.
G. G. SWARD

Causes of floating of pigments in paints and enamels. C. A. HOLKESVIK. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 477–91; *Am. Paint J.* **14**, No. 52D, 27; *Paint, Oil & Chem. Rev.* **90**, No. 17, 77–80; *Oil, Paint & Drug Reptr.* **118**, No. 19, 57–8(1930).—Floating or flooding of pigments is a concn. of one of the ingredients of a pigment mixt. of a paint at the surface to produce a different color from the interior of the film. If the appearance is uniform, the term flooding is used; if non-uniform, the term floating is used. Some of the causes of floating are difference in degree of dispersion of the pigment ingredients or difference in the solubilities of some of them, *e. g.*, Prussian blue in a chrome green. The finely dispersed pigment or soln. is then carried to the surface of the film by the convection currents created by the evapn. of the thinner. The ability of rosin to reduce floating troubles (*C. A.* **24**, 513) is ascribed to the rapid setting of gloss oils contg. it. Floating caused by soly. may be avoided or reduced by incorporation of pigments which adsorb the sol. ingredient. Unequal dispersion of solids may be overcome by proper selection or by protracted grinding.
G. G. SWARD

Synthetic resins in enamels and house paints. L. K. SCOTT, E. J. PROBECK AND OTTO MILETI. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 437–50; *Am. Paint J.* **14**, No. 52A, 31; *Paint, Oil & Chem. Rev.* **90**, No. 17, 84–6; *Oil, Paint & Drug Reptr.* **118**, No. 19, 60–1(1930).—Exposure tests were conducted on enamels, by using as vehicles glyptals of I, linseed fatty acid; II, tung oil fatty acid; III, corn oil; IV, castor oil types; and V, an amberol-tung oil 30 gallon varnish. The glyptals gave superior results with respect to gloss retention and cracking of films. V collected less dirt than the others because of more chalking. The av. order of the best qualities for the glyptals was I, II, III, IV last. Glyptals used in house paints also proved superior to linseed oil vehicle but the exposures had not progressed to a stage that differentiated between the types.
G. G. SWARD

Investigation of metallic soaps. II. The effect of soaps in paints. J. T. BALDWIN. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 492–506; *Paint, Oil & Chem. Rev.* **90**, No. 17, 87–90; *Oil, Paint & Drug Reptr.* **118**, No. 19, 56(1930); cf. *C. A.* **24**, 519.—The settling characteristics and consistencies of the paints referred to above for periods up to 9 to 15 months are recorded. With many soaps, the paints became solid, but with others, the consistency passed through a max. as aging proceeded and returned to the original value at the end of the period. Basic carbonate of Pb and lithopone possessed the most desirable aging properties.
G. G. SWARD

Oil absorption of pigments. R. SCHOLDER. *Farbe Lack* 1930, 478–9.—Review. G. G. SWARD

What is Persian red? K. WURTH. *Farbe Lack* 1930, 504.—Persian red was originally applied to an iron oxide pigment of a particular color obtained from Persia, but it now indicates color only and may be applied adjectively to any pigment. G. G. SWARD

Microscope tests on iron oxide colors. H. WAGNER. *Z. angew. Chem.* 43, 861–4 (1930).—See *C. A.* 24, 5513. E. J. C.

Grinding of dark para toner. C. ROSS ELLIOTT, *et al.* *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 451–60; *Am. Paint J.* 14, No. 52D, 27; *Paint, Oil & Chem. Rev.* 90, No. 17, 68–70; *Oil, Paint & Drug Reptr.* 118, No. 19, 54(1930).—A dark para toner was ground by 3 different operators in stone mills and in 4 different types of liquids, *viz.*, raw and boiled linseed oils, a long oil and a short oil varnish. Acid nos. as high as 16 and temps. as high as 79° had no deleterious effects on the pastes. No advantage was gained by sweating the pastes before grinding nor, in most cases, by passing the material through the mill more than twice. G. G. SWARD

The "aridyne"—a standard unit of drying power. COURTLAND F. CARRIER. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 37, 510–9; *Am. Paint J.* 14, No. 52D, 25; *Paint, Oil & Chem. Rev.* 90, No. 17, 71–3; *Oil, Paint & Drug Reptr.* 118, No. 19, 58–9(1930); cf. *C. A.* 24, 3660.—The word "aridyne," meaning drying power, is suggested as a name for the drying-power equiv. to that of a lead drier contg. 0.064 oz. of Pb. G. G. SWARD

Blown linseed oil, sulfo-linseed oil and sulfo-tung oil. A. HOLLANDER. *Farben-Ztg.* 36, 118–20(1930).—The superior waterproofness of films of sulfo-oils and blown oils is ascribed to a twofold gel structure which is present in the liquid oil. In addn. to the structure due to ordinary at. valence forces there is superimposed one due to mol. valence forces. S in particular is bound to the oil mols. by the latter. I and acid nos. obtained during aging of films of blown and sulfo-oils are given in support of the above theory. G. G. SWARD

Chinese tung oil seeds. ANON. *Bull. Imp. Inst.* 28, 267–73(1930).—A sample of nuts of *Aleurites fordii* from China consisted of 46% shell and 54% kernels. The latter contained 4.5% H_2O and on extn. with petr. ether yielded 55.9% (58.5% on the dry basis) of a yellow oil having the following characteristics: d_{16}^{15} 0.9428, acid value 0.44, sapon. value 192.3, I no. (Wijs, 3 hrs.) 179.2%, unsaponifiable matter 0.9%, n_{40} 1.5155, heat test (Browne) 11 min., solidifying pt. of fatty acids 30.0°. These agree with the requirements of the British and American specifications, except that the unsaponifiable is slightly above the max. desirable. The residual meals left after extn. of the oil from the entire kernels and the whole nuts, resp., had the following compn.: H_2O 10.3, 9.2; crude proteins 37.9, 22.4; fat 0.4, 0.5; N-free ext. 35.9, 20.9, crude fiber 7.8, 42.1; ash 7.7, 4.9; nutrient ratio 1:1.0, 1:1.0; food units 132, 78. They would be valuable as *feeding stuffs*, provided they are proved harmless to animals; and both meals would be suitable for use as *fertilizers*. Two samples of nuts of *Aleurites montana* from China consisted of 43.5 and 47.5% shell and 56.5 and 52.5% kernel. The latter contained 4.5 and 5.9% H_2O and 59.8 and 56.3% oil (62.6 and 59.8% on dry basis). The oils had the following characteristics: d_{16}^{15} 0.9381, 0.9405; acid value 12.1, 1.5; sapon. no. 191.5, 192.6; I no. (Wijs 3 hrs.) 163.1, 170.0; unsaponifiable matter 0.6, 0.7; n_{40} 1.506, 1.509; heat test (Browne) 24, 20.5 min.; solidifying pt. of fatty acids 38.2, 41.1°. These agree with the requirements of the British and American specifications, except that the n is lower and the time required for polymerization considerably greater. The compn. of the residual meal from the extn. of the kernels only was: H_2O 9.7, 12.8; crude proteins 37.9, 47.9; fat 1.6, 0.7; N-free ext. 33.4, 24.7; crude fiber 7.1, 6.8; ash 10.3, 7.1%; nutrient ratio 1:1.0, 1:0.5; food units 132, 146. The compn. of the residual meal from the extn. of the whole nuts in 1 sample was: H_2O 10.1, crude proteins 15.9, fat 0.8, N-free ext. 19.3, crude fiber 49.1, ash 4.8, nutrient ratio 1:1.3, food units 61. Provided that the meal from the kernels possesses no toxic properties it should prove of value as a *feeding stuff*, but the meal from the undecorticated nuts would be of much less value. Both meals should be suitable for use as *fertilizers*. A. PAPINEAU-COUTURE

The blooming of varnish films. WILHELM KRUMBHAAR. *Am. Paint & Varnish Mfrs.' Assoc. Circ.* No. 370, 520–32; *Am. Paint J.* 14, No. 52A, 30; *Paint, Oil & Chem. Rev.* 90, No. 17, 59–62; *Oil, Paint & Drug Reptr.* 118, No. 19, 59–60(1930).—Blooming is defined as an iridescence which sometimes appears on fresh varnish films. It is probably due to cryst. oxidation products of the drying varnish and occurs most frequently in rapidly changing atms., such as drafty corridors, etc. Pb, Co and Zn have a tendency

to produce blooming but Ca and Mn do not. To be non-blooming a linseed oil-rosin varnish must contain at least 3 parts of oil to 2 parts of rosin. On the other hand, tung oil behaves as a resin and no amt. will prevent bloom. Sierra Leone, Congo, Brazil, Manila and Kauri gums permit bloom, the amts. increasing with the type of resin in the order named. "Running" does not decrease the tendency. Synthetic resins and ester gum also permit blooming. High cooking temps., *e. g.*, over 400°F., do not prevent blooming. The nature and manner of using thinners have no effect except that blooming may occur if used at temps. over 400°F. G. G. SWARD

Effect of method of application on durability of spar varnish. C. F. CARRIER. *Am. Paint & Varnish Mfrs.' Assoc., Circ.* No. 370, 507–9; *Paint, Oil & Chem. Rev.* 90, No. 17, 91(1930).—Boiled linseed oil and varnish seem to be of equal value as primers under varnish. Both are superior to lithopone-ocher or lead-zinc paints. Cf. *C. A.* 24, 514. G. G. SWARD

Colors for lacquers. J. C. ALSEE. *Ind. Finishing* 6, No. 11, 28, 33(1930).—A brief discussion of the qualities to look for in the choice of colors for lacquers. Permanency, oil absorption, opacity and grinding technic are dealt with in particular. D. THUESEN

Various grades of lacquer nitrocellulose. A. OTT. *Nitrocellulose* 1, 173–7(1930).—Tables of characteristics of all grades available in Germany are shown. E. M. S.

Resin studies. VII. ERICH STOCK. *Farben-Ztg.* 36, 69–70(1930); cf. *C. A.* 24, 4409.—The acid no., sapon. no., sintering pt., m. p., ash and soly. in a few common liquids and their behavior when subjected to capillary analysis are given for earth resin, camphor resin and Siam damar. G. G. SWARD

A new color test for rosin. H. C. COHEN. *Farben-Ztg.* 36, 121(1930).—When chlorosulfonic acid in $CHCl_3$ (1:5 by vol.) is added to a soln. of rosin in $CHCl_3$ a violet-red color is produced. Ester gum and the albertols give a rose-red color. Tung, linseed and stand oils do not interfere. G. G. SWARD

Analytical methods for textile soaps (LEVITT) **27.** Dhupa kernels from India (ANON.) **27.** Apparatus for agitating the contents of containers such as foods, paints, etc. (U. S. pat. 1,780,333) **12.** Oxidizing mixed fats, oils, waxes and resins (U. S. pat. 1,780,632) **27.** Substantially pure finely divided C (U. S. pat. 1,780,154) **18.**

Cold water paint. LEON H. LARSON (to Kalbfleisch Corp.). U. S. 1,781,019, Nov. 11. Ca aluminate and Ca caseinate are suspended in an alk. aq. soln. such as lime water.

Mixing paint. HENRY H. MAPOTHER, JR. (to Vacuum Process Corp.). U. S. 1,781,648, Nov. 11. Finely ground dry pigments are subjected to a vacuum and then mixed with a liquid vehicle and uniformly dispersed while maintaining the vacuum. App. is described.

Apparatus for mixing and grinding ingredients of paints. JOSEPH B. CARPER. U. S. 1,781,435, Nov. 11. The materials are circulated from and returned to a tank with stirring arms, by a gear pump which serves also for grinding the paint ingredients together.

Disk mill for grinding paints, inks, etc. DISC BAR MILLS, LTD., and E. A. WHITE. Brit. 331,762, Sept. 17, 1929. Structural features.

Antifouling or insecticidal paint. ROBERT Q. MCGREGOR. U. S. 1,779,183, Oct. 21. White lead, lead oxide, Paris green, glycerol and linseed oil are used together.

Preparing metal surfaces such as those of automobile bodies for painting. JAMES H. GRAVELL (to American Chemical Paint Co.). U. S. 1,781,507, Nov. 11. The metal is coated with H_3PO_4 and then treated with a material such as Na_2HPO_4 adapted to convert the H_3PO_4 into a NaH phosphate. Cf. *C. A.* 24, 4175.

White pigment. EDWARD C. HOLTEN (to Sherwin-Williams Co.). U. S. 1,778,975, Oct. 21. An intimate mixt. is formed comprising a zinc-lead pigment and a Ti oxygen compd.

Litharge. EDGAR KNAPP and CARL G. ALLGRUNN (to Niagara Sprayer Co.). U. S. 1,779,003, Oct. 21. Air is forced up through molten Pb to effect partial formation of PbO and the PbO floating on the surface is continuously skimmed off as it is formed and conveyed to a finishing furnace where it is stirred in contact with O. App. is described.

Lithopone. SACHTLEBEN A.-G. FÜR BERGBAU UND CHEMISCHE IND. Fr. 684,212, Oct. 30, 1929. Lithopone contg. an excess of BaS is calcined without oxidation and cooled in water contg. sol. sulfates but no compds. of Zn, Ca or Mg, to make it resistant to the weather.

Reducing the zinc oxide content of lithopone. AXEL B. LAFTMAN (to Grasselli Chem. Co.). U. S. 1,780,559, Nov. 4. In making lithopone, an aq. soln. contg. $ZnSO_4$ is treated with an aq. soln. contg. Ba sulfide to form a slurry contg. crude lithopone and any HOAc-sol. compds. assocd. with the ppt. are transformed into water-sol. compds. by treatment with a small proportion of acid; the acidified slurry contg. water-sol. Zn compds. is treated with a quantity of Ba sulfide calcd. to react with the water-sol. Zn compds. for production of addnl. crude lithopone.

Coating surfaces such as wood or metal with varnishes containing cellulose derivatives. ERICH RICHTER and WALTER BECKER (to I. G. Farbenind. A.-G.). U. S. 1,778,813, Oct. 21. The surface is prepd. by the application of an intermediate coating of a soln. of a cellulose deriv. such as cellulose dilaurate or mono-acetate-distearate in which at least one OH group of the cellulose mol. is esterified by a higher fatty acid.

Coating surfaces with nitrocellulose varnishes. HANS F. SCHULZ. U. S. 1,780,844, Nov. 4. Surfaces such as wood or metal are coated with a primary binding layer contg. nitrocellulose of a N content above 12.6% and with overlying layers of lower N content than the primary layer, which serves to provide good adhesion of the coatings.

Coating metal surfaces with varnish-like materials containing metal powder. W. BAUR. Brit. 331,550, April 3, 1929. In the coating of iron or other surfaces, powd. metal such as Al or brass is used suspended in a varnish-like liquid which on heating hardens and is burned in to the surface after hammering, rolling or pressing to flatten out the particles of the coating metal. As the vehicle there may be used a product formed by heating castor oil with ZnO or a varnish prepd. by esterifying a copal or other suitable resin with glycerol and dilg. with linseed oil or MeOH and turpentine. Addnl. metal as foil or powder may be applied before the hammering or other mech. treatment.

Coating compositions. WALTER E. LAWSON (to E. I. du Pont de Nemours & Co.). U. S. 1,780,652, Nov. 4. Tetrahydrofurfuryl alc. is used as a solvent with a polymerized vinyl compd. such as a polymer of vinyl chloride or vinyl acetate.

Coating magnesium and its alloys. H. SUTTON, A. J. SIDERY, L. F. LE BROCQ and C. BRAITHWAITE. Brit. 331,853, April 8, 1929. A coating (which forms a suitable base for paints, enamels, varnishes and lacquers) is obtained on Mg or its alloys by immersion in a heated neutral or acid aq. soln. contg. chromates and dichromates of an alkali metal together with a compd. or salt of Al such as K alum. A temp. of 95–100° is suitable, and various details of the treatment are described.

Coating paper or other surfaces with synthetic resins. THEODORE F. BRADLEY (to American Cyanamid Co.). U. S. 1,780,375, Nov. 4. A surface such as paper is treated with an aq. soln. of a water-sol. salt such as the NH_4 salt of a "polybasic acid-polyhydric alc. resin" such as a resin formed from linseed oil fatty acid-glycerol phthalate and the treatment may be followed by drying to render the material insol.

Coating furniture, etc., with artificial resins. F. OEHRING. Brit. 331,870, April 5, 1929. Furniture, boxes, etc., for indoor or outdoor use and which may be formed of wood, metal, "xylolite" or paper-like or ceramic materials are coated or lined with artificial resin plates carrying on the back an intermediate veneer which may be attached by cold casein glue or liquid artificial resin.

Lacquers containing cellulose derivatives. ANGELO KNORR (to I. G. Farbenind. A.-G.). U. S. 1,780,883, Nov. 4. Lacquers are formed contg. cellulose derivs. in which the H of at least one OH group of the cellulose is substituted by alkyl or acyl, *e. g.*, nitrocellulose, ethyl cellulose or cellulose dilaurate, together with dioxane and a liquid hydrocarbon material such as toluene, C_6H_6, etc.

Lacquers and plastics from cellulose derivatives. IMPERIAL CHEMICAL INDUSTRIES, LTD. and B. W. FOSTER. Brit. 331,837, Jan. 3, 1929. Substantially anhyd. materials for manuf. of *lacquers, celluloid-like material, floor coverings, leather substitutes*, etc., are prepd. by kneading water-wet cellulose esters and ethers with a plasticizing and softening medium including a volatile gelatinizing agent (which may be a water-miscible or partly miscible solvent such as ethylene glycol ethyl ether, Et lactate and MeOAc or a water-immiscible solvent such as BuOAc and $CHCl_3$, or mixts. of these two types), which effects sepn. of the water substantially without evapn. so that it can be poured off. Non-volatile gelatinizers and various modifying agents may be added, and various details and examples of procedure are given.

Diethylene glycol ester of abietic acid. GEORGE M. NORMAN (to Hercules Powder Co.). U. S. 1,779,710, Oct. 28. This compd. is made by heating diethylene glycol with rosin and is suitable for use in *lacquers* and *varnishes*.

Plastic coating materials from tars, etc. FRANKFURTER GASGES. and H. W. HOFLZER. Brit. 331,846, April 4, 1929. In prepg. material for use in *lacquers* or other

coatings or binding agents, coal tar, lignite tar, coumarone resin or the like is heated with a sulfurous ext. obtained from spent sulfurous gas purification materials (suitably by extn. with CS_2 or with C_2HCl_3 or by extraction *in situ* with the use of tar oil or tar oil vapor from the tar employed in the process). Catalysts may also be used such as Fe chlorides, Mn sulfate, Na_2SO_4, NaOH, H_2SO_4 or polymerized CH_2O (which in some instances may be derived with the S from the same material by use of a suitable extracting medium).

Condensation product of China wood oil and phenol. ALFRED THAUSS and GUSTAV MAUTHE (to I. G. Farbenind. A.-G.). U. S. 1,779,345, Oct. 21. China wood oil and phenol are caused to react in the presence of dil. H_2SO_4 and the reaction mass is treated with concd. H_2SO_4. A resinous product is obtained which in the form of its alkali metal salts is easily sol. in water, and suitable for treating textile materials.

Impregnating cellulose material with synthetic resins. MAGNASCO, ROGGERO & Co. Brit. 331,851, April 8, 1929. Wood shavings, leaves, woven fabrics or other cellulosic material is treated successively with a 1% NaOH soln. at 100° and with an aq. soln. of an oxidizing acid such as a mixt. of 5% H_2SO_4 and HNO_3, washed and dried after each treatment, and finally neutralized with NH_3, then impregnated with a synthetic resin soln. or with ingredients which form a synthetic resin, heated and pressed to produce an insol. form of the resin, while preserving the original texture of the material

Resinous products from tar and pitch. G. T. MORGAN, F. S. SINNATT and D. D. PRATT. Brit. 331,542, Feb. 4, 1929. Pitch such as that remaining after a distn. of high- or low-temp. tar or the insol. portion left by treating tars with light petroleum is treated with a solvent such as ether, C_6H_6 or low-temp. tar spirit, the soln. is sepd. from undissolved matter and is pptd. with petroleum or the solvent may be evapd. from it. Constituent resins may be obtained from the soln. by (1) extn. with NaOH soln. or NaOH and brine, followed by carbonation and acidification to obtain resinols and resinoic acids, (2) extn. with inorg. acids followed by decompn. with alkali to obtain resinamines, (3) evapn. of the soln. to leave a residue of resinenes. The crude fractions may be purified by dissolving in org. solvents and repptg. with petroleum. Various details of procedure are described.

Substituted guanidine-aldehyde condensation product. CHARLES M. STINE (to E. I. du Pont de Nemours & Co.). U. S. 1,780,636, Nov. 4. A product which is suitable for manuf. of molded articles comprises an infusible synthetic resin contg. a polymethylol-substituted guanidine which may be prepd. by heating a guanidine salt or deriv. with CH_2O soln. Several examples are given.

Synthetic resin. BORIS N. LOUGOVOY. U. S. 1,779,551, Oct. 28. A product which is substantially colorless is obtained from phenol, CH_2O and urea, incorporated with $(CH_2)_6N_4$.

Linoxyn-like products. V. SCHOLZ and ATLAS AGO CHEMISCHE FABRIK A.-G. Brit. 332,257, March 13, 1929. Linseed oil or other suitable drying or non-drying oil contg. unsatd. groups or their fatty acids is blown with air or other O-contg. gas until no further oxidation or polymerization can take place by this means and the product is then kneaded with air to carry the oxidation and polymerization still further and produce a light colored, granular material of relatively high m. p. The process may be carried out in the presence of a small proportion of a catalyst such as PbO or Pb linoleate at temps. of 60–150° and the kneading may be at a temp. of about 100°. Org. bases such as aniline, naphthylamine or urea may be added during the blowing or kneading, as may also resins, pigments, fillers, etc. Numerous examples and details of procedure are given.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Composition of the fatty acids present as glycerides in the liver oil of the thresher shark (Alopoecia vulpes). JOHN A. LOVERN. *Biochem. J.* **24**, 866–9(1930).—Further evidence is presented to show that there is a relation between the amt. of squalene present in the non-glyceride portion of the oil and the nature of the fatty acid constituents (cf. *C. A.* **24**, 5520). BENJAMIN HARROW

Sunflower seed from Southern Rhodesia. ANON. *Bull. Imp. Inst.* **28**, 272–274–6(1930).—Six samples of different varieties of seeds were examd. to ascertain which was most suitable for cultivation, and gave the following results: H_2O 6.6–7.6, oil 24.1–29.6% (26.1–31.8% on the dry basis), acid value of the oil 0.5–0.9. A. P.-C.

Soy-bean extraction residues from different methods of treatment. PH. MALKO-

MESIUS AND W. SCHRAMM., *Landw. Vers. Sta.* **110**, 33–47(1930).—The content of the digestible protein of soy-bean meal varies partly with the raw material and partly with the method of extn. The fat and lecithin contents depend only on the method of extn. The most useful basis of purchase is the content of protein plus fat. JOHN R. HILL

The oil-bearing royal palm tree seed (Credoza regia H. B. and K.) of the West Indies. F. HEIM DE BALSAC, G. S. DAGAND, H. HEIM DE BALSAC, L. LEFÈVRE, J. MAHEU AND A. PARVEAUD. *Bull. agence gén. colonies* **23**, 815–33(1930).—The botanical characteristics of the tree, the structure of the seed and the microscopic characteristics of the oil cake are described. The seed consists of 39% shell and 61% kernel. Extn. of the crushed seed with Et_2O yield 20% of fat, corresponding to 32% on the kernels (one test gave 40%). Characteristics of the fat: white, semi-solid, of soft consistency at 18–20°; the solid portion is white and the supernatant oil pale yellow; at 25° it is completely liquid and of a beautiful straw color; it is easily supercooled and can remain liquid at 0°; sapon. no. 215, I no. 44.5, Reichert-Meissl no. 3.7, Hehner no. 90.1, Ac no. 21.4, acid no. 20.5, glycerol 6.8%, mono- and di-glycerides present, unsaponifiable matter (consisting of phytosterol and a light yellow coloring matter) 0.6%, d_0 (solid) 0.935, d_{20} (liquid) 0.923, m. 24.5°, solidifying pt. 20.3°, elaidin test pos., O absorption 1.5% in 7 days, hexabromides none, heat tests—Maumené (H_2SO_4) 41°, S chloride 51°, Br 13°; resins none, alkaloids none, glucosides none. Color reactions: H_2SO_4 gives red, rapidly turning dark brown; H_2SO_4-HNO_3 gives dark brown in the cold. and blackish brown after heating 5 min. at 100° and cooling; HNO_3 gives no coloration; NH_4OH gives a thick, white emulsion; NH_4OH and Hg give a thick, white emulsion; Ac_2O does not give the characteristic fugitive violet coloration produced by resins. Characteristics of the fatty acids: sapon. no. 238, neutralization no. 238, mean mol. wt. of total acids 235, mean mol. wt. of solid acids 233, mean mol. wt. of liquid acids 300, Ac no. 23.8, lactone-anhydrides none, volatile sol. acids (as butyric) 2.1%, solidfying pt. of total acids 24.2°, m. p. of total acids 21°, solidifying pt. of solid acids 27.8°, m. p. of solid acids 28.7°, I no. of solid acids 3.7, I no. of liquid acids 58.1, satd. fatty acids (consisting of stearic 28, myristic 35, palmitic 37%) 48%, satd. fatty acids (exclusively oleic) 52%, hydroxylated fatty acids present. The compn. of the residue from the extn. of the crushed seed was: H_2O 12.10, ash 5.21, crude protein 8.07, reducing sugars 5.64, nonreducing sugars 2.08, starch trace, saccharifiable carbohydrates (mannocellulose and others) 32.30, crude fiber 12.04, undetd. 22.56%. The fat is similar to the fats of the coconut, particularly the palm group; it is suitable for *food purposes* and for *soap making;* the solid portion can be sepd. for use as a food and the liquid portion for soap making; the oil cake is suitable as a stock food. A. PAPINEAU-COUTURE

Moringa aptera seed from Egypt. ANON. *Bull. Imp. Inst.* **28**, 276–9(1930).—The seed consisted of 51.2% shell and 48.8% kernel. The latter contained 4.9% H_2O and yielded 50.0% oil, equiv. to 52.6% on the dry basis and to 24.4% on the whole seed as received. The oil had: d_{15}^{15} 0.9151, n_{40} 1.461, acid value 0.5, sapon. value 188.2, I no. (Wijs, 3 hrs.) 71.2%, unsaponifiable matter 0.5%, solidifying pt. of fatty acids 28.1°. The oil is very similar to that of *Moringa pterygosperma* and has very similar consts., except the solidifying pt. of the fatty acids which is much lower with *M. aptera*. The compn. of the residual meal was: H_2O 8.7, crude proteins 48.6, fat 2.6, N-free ext. 28.0, crude fiber 6.6, ash 5.5%, nutrient ratio 1:0.7, food units 156. It is free from cyanogenetic glucosides, but probably contains alkaloids and saponin, which would prevent its use as feeding stuff; it would be suitable for use as a *fertilizer*. A. P.-C.

Dhupa kernals (Vateria indies) from India. ANON. *Bull. Imp. Inst.* **28**, 279–81 (1930).—The kernels contained 7.6% H_2O. Extn. with petr. ether (b. 40–60°) yielded 21.4% of greenish white, fairly soft fat, having a very slight odor; extn. of the residue with Et_2O and then with Me_2CO yielded 3.0 and 7.2% of brittle, resinous exts. Extn. of the kernels with benzine (b. 90–110°) yielded 22.8% of greenish cream fat, greener than that obtained with petr. ether, but otherwise of similar character. Extn. of the kernels with trichloroethylene yielded 22.6% of a cloudy brown fat which, after filtration, was brownish cream. The petr. ether ext. gave the following results on analysis: d_{15}^{100} 0.8585, m. p. 34.2°, acid value 1.0, sapon. value 190.3, I no. (Wijs, 3 hrs.) 45.9%, unsaponifiable matter 0.9%, n_{40} 1.4588, solidifying pt. of fatty acids 52.7°. These results agree with the figures previously recorded by various investigators, except that the I no. in the present instance is somewhat higher. The residual meal from the petr. ether extn. was light brown, had a strong bitter taste, and had the following compn.: H_2O 8.8, Et_2O ext. 4.1 (contg. Et_2O-sol. substance other than fat), crude proteins 6.2, N-free ext. 73.8 (including resinous matter sol. in Me_2CO), crude fiber 5.0, ash 2.1%, nutrient ratio 1:13.4, food units 100, cyanogenetic glucosides none, alkaloids none. Because of the

low percentage of proteins and its bitter taste it would be unsuitable for use as a feeding stuff and could be employed only as a *fertilizer*. A. PAPINEAU-COUTURE

The evaluation of Turkey-red oils by their properties. H. POMERANZ. *Am. Dyestuff Reptr.* 19, 672–4(1930).—The requirements of Turkey-red oils are discussed. MILTON HARRIS

New commercial emulsifying agents. H. BENNETT. *Ind. Eng. Chem.* 22, 1255–6 (1930).—See *C. A.* 24, 4415. E. C. K.

Analytical methods for textile soaps. BENJAMIN LEVITT. *Am. Dyestuff Reptr.* 19, 667–71(1930).—Methods of analyzing for moisture, free caustic, carbonate, Na silicate, total alkali and total fat, unsaponifiable matter and glycerol are given. Methods for titer and I value of fatty acids are discussed, also a detn. of Rosin. M. H.

Analysis of soap containing water glass. K. SCHERINGA AND J. W. AHRLICHS. *Pharm. Weekblad* 67, 1070–2(1930).—Soap powders occasionally contain water glass. In the analysis of such prepns., a sepn. of soap from carbonate and silicate is usually attempted by means of EtOH. This sepn. is, however, troublesome and incomplete. For detn. of SiO_2 a convenient procedure is to ignite a 5 g. sample in a porcelain dish over a free flame until the evolution of inflammable gas ceases. The residue is acidified and boiled, then collected on a filter and weighed. Repeated evapn. with HCl is unnecessary. The wt. of SiO_2 found multiplied by 1.3 gives the wt. of dry water glass. A. W. Dox

Investigation of metallic soaps (BALDWIN) **26.** Acids of montan wax (HOLDE, *et al.*) **21.** Pressure filter for filtering oil (U. S. pat. 1,780,663) **1.** Pressure filter for oil (U. S. pat. 1,780,723) **1.**

Synthetic fats. T. P. HILDITCH. Brit. 331,880, March 11, 1929. A mixt. of fatty acids contg. about 35–65% of satd. fatty acids and the balance unsatd. fatty acids is esterified by heating with a deficiency of glycerol (suitably under reduced pressure). Examples are given of the production of mixed fats resembling lard, tallow and mutton tallow.

Oxidizing mixed fats, oils, waxes and resins. WILHELM PUNGS (to I. G. Farbenind. A.-G.). U. S. 1,780,632, Nov. 4. A retort is charged with inert heat-cond. material such as Raschig rings and a mixt. to be oxidized such as resin or China wood oil and lignite wax is fed into the retort to a point below the top of the inert charge so that when the mixt. swells during the reaction it will be in contact with the inert material, and a strong current of air is passed through the mixt. at a temp. of about 160–70° to effect oxidation. App. is described.

Sulfonated hydroxy fatty acids. I. G. FARBENIND. A.-G. Brit. 330,904, March 18, 1929. Higher unsatd. hydroxy fatty acids or their esters such as castor oil are treated with gaseous SO_3 while stirring and cooling (preferably in the presence of an org. solvent or diluent such as CCl_4, perchloroethane, C_2Cl_6 or C_2HCl_3). The SO_3 may be passed over the material in a current of dry inert gas such as air or N, and if desired the acids or esters may be preliminarily treated with sufficient H_2SO_4 monohydrate or chlorosulfonic acid to esterify the hydroxy groups, followed by the treatment with SO_3.

Copra drier. RAMON TAN (to Filomena Arias). U. S. 1,780,047, Oct. 28. Structural features.

Soap cakes with an outer solid shell and a filling of soap of spongy structure. ROBERT S. BLAIR. U. S. 1,780,330, Nov. 4. Various details of manuf. are described.

Spray-drying soap. EARL P. STEVENSON and BEN B. FOGLER (to Arthur D. Little, Inc.). U. S. 1,779,516, Oct. 28. Particles of an atomized fluid soap soln. are subjected to the drying effect of a heated air current and the particles are sepd. by gravity from the heated air current at a predetd. stage of the drying process and cooled by falling through a current of suitably conditioned air. App. is described. U. S. 1,779,517 relates to a soap product made up of discrete particles having a void-defining shell of puffed soap as obtained by spray desiccation, the soap substance of which contains at least 15% moisture.

Soap threads. ADOLF WELTER. U. S. 1,779,301, Oct. 21. See Brit. 319,807 (*C. A.* 24, 2627).

Soap threads, flakes and strips. A. WELTER. Brit. 331,268, March 26, 1929. Soap powder (formed by atomizing liquid soap) is pressed into threads, flakes or strips, with or without addn. (to the liquid soap before atomizing) of waterglass, borax, soda or K_2CO_3. Various details of procedure are described.

Continuation and conclusion of the discussion of the Oxford process. F. CHAMMIER, O. SPENGLER, KÖHLER AND H. CLAASSEN. *Deut. Zuckerind.* **55**, 381–4(1930); *C. A.* **24**, 5528. J. F. LEETE

The valuation of raw sugar according to its affinability by the method of the Institut für Zucker-Industrie. O. SPENGLER. *Deut Zuckerind.* **55**, 533–4(1930).—A discussion showing how the increasing use of the short color method results in better sugar. In the campaign 1926–27 only 800 samples were examd. while over 8000 examns. are expected for the 1929–30 campaign. The av. color value is now 4.21 against 3.2 in 1926–27. J. F. LEETE

Computation of the sugar production in raw sugar factories. Q. JEDLIČKA. *Z. Zuckerind. Čechoslovak. Rep.* **54**, 447–8(1930).—A discussion with computations. J. F. LEETE

Control of the work on low purity (sugar) products. E. TROJE. *Deut. Zuckerind.* **55**, 141–2(1930).—A discussion. J. F. LEETE

Control of the work on low purity (sugar) products. P. KÜHLE. *Deut. Zuckerind.* **55**, 301–2(1930).—A discussion. J. F. LEETE

The magnitude of contraction in impure sugar solutions and its influence on the difference between true and apparent purity. P. KÜHLE. *Centr. Zuckerind.* **38**, 736–9, 762–4(1930).—Theoretical discussion, exptl. data, computations, tables and diagrams. K. concludes that there is a const. relation between true and apparent purity, that the varied non-sugars present in juices cause the seeming lack of const. relation and that it is the Brix table, not the sp. gr. of impure sugar, which is the cause of high sp. gr. of sugar solns. J. F. LEETE

The volumes of sugar solutions at various temperatures. L. KARAS. *Z. Zuckerind. Čechoslovak. Rep.* **55**, 15–6(1930).—K. recalcd. Gerlach's table to 5 decimals, taking the vol. at 20° instead of 17.5° as unity. The new table is reproduced. J. F. L.

Centrifuging of sugar juices. P. HONIG AND W. F. ALEWYN. *Mededeel. Proefsta. Javasuikerind.* **1930**.—Results of expts. on subjecting sugar juices to centrifugal force during crop 1928 and 1929 are reported. The largest type of a de Laval machine was used, developing 6000 r. p. m. and a sludge capacity of 10–14 kg. The best results were obtained when the molasses was diluted to 70 Brix and heated to 65°. Comparative tests with a small lab. separator showed that when 80% of the suspended matter was removed the av. increase in purity of sulfitation sirup was 0.3, and of diluted final molasses 4 points. In judging the effect of sepn. the increase in purity is not the main point; therefore, for every test there was detd. the amt. of sepd. product, the analyses of

the product, weight of the sludge and analyses of the sludge. Not one of the exptl. installations was large enough to make a complete factory test, but at Beran and Tjoekir it was concluded that the molasses strikes purged better when as much as possible of the molasses drawn in had been centrifuged. Sepg. draw-in molasses for the third strikes is considered to be the most advantageous as even after centrifuging or filtering thick juice there is always a further flocculation upon concn. Lab. tests showed that sepg. had a large influence on the quality of the sugar and on the centrifugal work. The results of analyses of sludges showed a big difference between carbonatation and defecation mills; CaO in sludge of defecation mills was 35% and of carbonatation mills 92%. P. R. P.

The properties and composition of the slow- and rapid-settling mud particles in first saturation juice. H. CLAASSEN. *Centr. Zuckerind.* **38**, 1066(1930).—No difference was found in size, shape or chem. compn. of the lower and upper layers of the ppt. J. F. LEETE

Catalytic influences in the coloration of alkaline sugar liquors on heating. O. SPENGLER AND F. TÖDT. *Z. Ver. deut. Zuckerind.* **80**, 673–89(1930).—The coloring of alk. sugar juices on being heated is increased by traces of Fe salts, and decreased by the addn. of a very small quantity of KCN. This finding leads to the assumption that the coloring of sugar juices is catalyzed by Fe. Further expts. in which the liquid-air boundary was altered confirmed this belief. A significant decrease in coloration was also obtained by using Na_2SO_3 and $Na_4P_2O_7$. The question whether the destruction of sugar is likewise catalyzed by Fe was tested by observing the decrease in polarization. Result: Catalytic influences in all probability play a part in sugar destruction, but exptl. demonstration is not possible for several reasons. F. CAMPS-CAMPINS

The determination of lime in sugar factory juices by Blacher's method. K. SOLON. *Deut. Zuckerind.* **55**, 457–8(1930).—S. discusses the oxalate-permanganate method and those of Pellet and of Blacher. Exptl. data show that the 3 methods give results identical to the third decimal. Blacher's method is recommended for rapidity and for the fact that alky. can be detd. in the same sample; disadvantages are the lesser accuracy and the necessity of neutralizing the soln. to phenolphthalein. **Reply.** S. BÖTTGER. *Ibid* 700.—B. states that the method is suitable only for the *detn. of hardness in water.* J. F. LEETE

Lime determination in technical cane sugar juices and molasses with soap solution. M. VAN DER KREKE AND K. DOUWES DEKKER. *Mededeel. Proefsta. Javasuikerind.* **1930**.—The authors refer to the work of Spengler and Brendel (*C. A.* **23**, 539) who recommend CaO detn. in juices by soap titration. At the expt. station a series of comparative tests was made to det. the CaO as CaC_2O_4 or by pptn. with soap. Applied to molasses the results agree satisfactorily; with juices, however, a difference of 20% is found. This difference may be due to Mg salts or to absorbed ingredients. The results are best for carbonatation juices. P. R. P.

Density and concentration determinations in the Java sugar industry. K. DOUWES DEKKER AND TH. J. D. ERLEE. *Mededeel. Proefsta. Javasuikerind.* **1930**.—In analytical and other chem. work in Java beginning with crop 1931 the true cc. with a normal temp. of 27.5° will be employed instead of the Mohr cc. to comply with the resolutions of the international commission in Paris in 1900 and to simplify the purchasing of glassware. The polarizations will continue to be reported at 20°. The principles of the detns. of sp. gr., concn. and standardization of measuring instruments are discussed. P. R. P.

Some noteworthy results of testing varieties of sugar cane in Cuba and their significance for the beet-sugar industry of Europe. R. E. GROTKASS. *Centr. Zuckerind.* **38**, 789–90(1930).—Tables show the value of cane selection in increasing sugar yield per acre. G. therefore recommends intensive selection of beets. J. F. LEETE

Results of the sugar-beet experiments carried on by the association of agricultural, forestry and industrial-agricultural experiment stations in Czechoslovakia during the year 1929. F. CHMELAŘ AND J. ŠIMON. *Z. Zuckerind. čechoslovak. Rep.* **55**, 1–8(1930). J. F. LEETE

Should beet roots be dried immediately or should the sugar be recoverd first? E. TROJE. *Deut. Zuckerind.* **55**, 747–8(1930).—Discussion and calcns. Conclusion: Immediate drying is profitable only when very high prices for dried beets are coincident with very low prices for sugar. J. F. LEETE

A suggestion for a device for working up beet roots. J. HAMOUS. *Z. Zuckerind. čechoslovak. Rep.* **54**, 424(1930).—A description with sketch is given. J. F. LEETE

Results of experiments in beet-sugar factories. BERNER. *Centr. Zuckerind.* **38**, 787–9(1930).—A summary of results of expts. dealing with evaporators, driers, plant efficiency, heat balance, etc., in a group of factories. J. F. LEETE

The determination of the true sugar content of beets in the sugar factory. V. MAREŠ. *Z. Zuckerind. čechoslovak. Rep.* **54**, 442–7(1930).—See *C. A.* **24**, 2629. J. F. LEETE

The pulverizing of sugar. W. TAEGENER. *Centr. Zuckerind.* **38**, 856–9, 880–2 (1930).—A technical and mathematical discussion. J. F. LEETE

Contribution to the study of cooler-crystallizers. P. HONIG AND W. F. ALEWYN. *Mededeel. Proefsta. Java Suikerind.* **1930**.—Different types of crystallizers are described. Expts. at Goedo with the LaFeuille and at Poerwodadi with the Werkspoor crystallizer, which is a continuous app., are described. The effects of cooling on the product and on the purity of the final molasses is discussed. For massecuites of high purity coolers with large cooling capacity are recommended but for the low grades a smaller unit will be sufficient, as they do not stand rapid cooling. A long crystallizer with a water spray on the outside is sufficient for low-grade massecuites. P. R. P.

The determination of invert sugar, especially in the presence of a large amount of sucrose. G. BRUHNS. *Deut. Zuckerind.* **55**, 422–3; 486–7(1930); cf. *C. A.* **24**, 1537.—A description of methods and exptl. data. J. F. LEETE

Experiments in sweetening-off mud presses. PÜTTER. *Deut. Zuckerind.* **55**, 539–40(1930).—Methods are described. In a sweetened-off mud press 0.5% sugar was found, which corresponds to 0.035% calcd. on the beet. J. F. LEETE

The utilization of the (world) over-production of molasses. H. CLAASSEN. *Deut. Zuckerind.* **55**, 1009–10(1930).—A discussion of molasses as *fertilizer*. J. F. LEETE

(Beet sugar) molasses prices and molasses utilization. H. CLAASSEN. *Deut. Zuckerind.* **55**, 536–8 (1930).—Germany faces the problem of utilizing the last $^1/_2$ of her molasses production in 1930. C. advocates the manuf. of power alc., as the existing tariff authorizes the enforcement, if necessary, of the regulation according to which importers or inland producers of benzine and benzene may be compelled to admix abs. alc. France has found that 50 parts of gasoline (benzine) and 50 parts of abs. alc. make a satisfactory *power fuel*. J. F. LEETE

The manufacture of rice starch. A. E. WILLIAMS. *Ind. Chemist* **6**, 387–9(1930). E. H.

The German tanners school at Freiberg i. Sa. ANON. *Ledertech. Rundschau* **22**, 69–72, 85–6(1930).—Annual report. I. D. C.

Report of the committee on qualitative tannin analysis. O. GERNGROSS. *Ledertech. Rundschau* **22**, 98–9(1930).—A review. I. D. C.

The fluorescence test of tannins. C. VAN DER HOEVEN. *Collegium* **1930**, 414–9.—The fluorescence colors are given of 62 solns. of tannins and syntans both before and after addn. of acid and alkali. I. D. CLARKE

Determination of the optimum relations in tanning with extracts of Rhus cotinus L. and Carpinus duinensis Scop. at different p_H values. A. N. ANFIMOFF AND A. P. PISSARENKO. *Collegium* **1930**, 419–27.—Samples of *Rhus. cotinus* L. and *Carpinus duinensis* Scop. were collected near the Black Sea in 1928. The former contained 16.3% of pyrogallol tannin and 16.82% of sol. nontannin; the latter contained 8.77% of pyrogallol tannin and 22.24% of sol. nontannin (H_2O 13%). p_H values were 4.12 and 3.92, resp. Exts. of both materials were most stable at p_H 4–5, and were pptd. by alkali; pptn. started at p_H 6 and was nearly 75% complete at p_H 8. The best leather was produced at about p_H 5. I. D. CLARKE

The value of the barks of "Cay-Xu" (Aegiceras majus Goertn.-Myrsin) and of "Chu-Me" (Phyllanthus emblica L.-Euphorb.) from Tonquin as tanning materials. F. HEIM DE BALSAC, J. MAHEU, L. LEFÈVRE AND A. PARVEAUD. *Bull. agence gén. colonies* **23**, 710–22(1930).—"Cay-Xu" bark contains: H_2O 15.27, tannin 6.60, nontannin H_2O-sol. 15.90, H_2O-insol. 62.23%. The saponin content (calcd. from reducing sugars after inversion in the autoclave) is 7.80%. Tanning tests gave a poor quality of leather. The tannin is almost exclusively catechuic, with only traces of pyrogallic tannin. "Chu-Me" or "Me-Rung" bark contains: H_2O 15.17, tannin 16.64, nontannin H_2O-sol. 5.76, H_2O-insol. 62.43%. There are no reducing sugars either before or after inversion under pressure. The tannin is almost exclusively catechuic, with but very little pyrogallic tannin. Tanning tests gave fairly satisfactory results, the leather lacking somewhat in flexibility, but having a soft grain. The ext. obtained at 100° is brownish red, and for some purposes it might be advisable to decolorize it.
A. PAPINEAU-COUTURE

Hide swelling in the light of the method of expressing water. H. OWRUTSKY. *Collegium* **1930**, 427–30; cf. *C. A.* **22**, 696.—Pieces of hide in a frame between paper, glass and wood squares were left for 10 min. under a 10-kg. wt. The loss of H_2O was detd. by wt.; thickness measurements were not conclusive. Pieces plumped in H_2O lost the most on pressing; HCl caused the greatest swelling. I. D. CLARKE

Safety limit on acid [in leather]. F. C. HILBERT. *Leather Manuf.* **41**, 177–8, 184–5(1930).—Pieces of sole leather, soaked in H_2SO_4 solns. to give % H_2SO_4 = 0.38 to 3.85 in the leather (Procter-Searle method), were dried and aged and observed for 9 months. At 4 months, leather showed loss of strength when $H_2SO_4 \geq 1.9\%$; at 9 months, leather showed loss of strength when $H_2SO_4 \geq 1.0\%$; all samples with added acid showed more or less darkening. From this work H. concludes that 0.50–0.75% H_2SO_4 should be the max. permitted in sole leather, preferably less if the leather is to be stored any long time. Arguing from the fact that belting, and bag, case and strap leathers are expected to last much longer than a shoe sole, he concludes that the max. limit for H_2SO_4 in such leathers should be 0.15–0.20%. H. B. MERRILL

Impregnated chrome sole leather. E. BAUMGARTNER. *Ledertech. Rundschau* **22**, 73–4(1930).—Impregnated chrome-tanned sole leathers were quite variable but wore longer than vegetable-tanned leather. They were not slippery in wet weather and only one sample lost appreciable impregnating material in boiling water under a 4-kg. wt.
I. D. CLARKE

Chemical changes in gelatin resulting from the method of storage. KENNETH V. THIMANN AND ALBERT B. PAGE. *Biochem. J.* **24**, 1058–60(1930).—Moist storage produces a gelatin chemically different from the normal dry-stored product. B. H.

The fine structure of gelatin micelles. O. GERNGROSS. *Ledertech. Rundschau* **22**, 99–100(1930).—A review. I. D. CLARKE

Quick determination of the moisture content of glue and gelatin. A. G. BELOUSOVA, M. A. TIMOKHINA AND A. M. BELOUSOV. *Zhur. Prikladnoĭ Khim* **3**, 741–6(1930). —A vacuum drying oven at 105° is used and analysis is made on weight basis. V. KALICHEVSKY

Advancement in analytical investigation by means of ultra-violet rays (FRANK) **7**. Estimation of minute quantities of tannins (OBERHARD, SCHALBEROWA) **17**. Use of dried seaweed as a preservative packing material, etc. (Brit. pat. 331,546) **12**. Lacquers and plastics from cellulose derivatives (Brit. pat. 331,837) **26**. Water-soluble product from fatty acids of wool fat (U. S. pat. 1,780,252) **25**. Sulfonating wool fat in the presence of a phenol (U. S. pat. 1,780,027) **25**.

Tanning agents from dried chlorinated products of degraded lignite. I. G. FARBENIND. A.-G. Brit. 332,204, April 15, 1929. The dried chlorinated product of degraded lignite and other materials such as described in Brit. 284,670 (*C. A.* **22**, 4778) and Brit. 323,781 (*C. A.* **24**, 3345) is extd. with an org. solvent such as acetone or crude wood spirit contg. 3% H_2O and the resulting soln. is evapd. or pptd. by addn. of a salt of a weak acid, a base or an org. precipitant and the ppt. is dried. Various details are given.

Tanning compositions. I. G. FARBENIND. A.-G. Brit. 331,216, March 25, 1929. Sol. tanning compns. are obtained by condensing 3 mol. proportions of resorcinol or pyrogallol with 1–1.5 mol. proportions of benzaldehyde or a substitution product such as *o*-chlorobenzaldehyde, in an aq. medium and in the presence of a small proportion of acid such as HCl or H_2SO_4, and interrupting the reaction by neutralizing the acid when little or none of the phenol can be detected with $FeCl_3$. Several examples with details are given.

Tanning composition. ALBRECHT SCHMIDT (to I. G. FARBENIND. A.-G.). U. S. 1,780,983, Nov. 11. An emulsion of an animal fat such as train oil, wool fat or tallow in an aq. soln. of dimethylcellulose is used in various tanning or fat-liquoring processes.

Tanning hides. I. G. FARBENIND. A.-G. Brit. 332,270, April 15, 1929. Tanning agents are prepd. by incorporating Cl-contg. water-sol. products from degraded lignite with gelatin-pptg. water-sol. condensation products of hydroxyaryl compds. and aldehydes contg. no sulfonic groups such as the products obtained by condensing di- and poly-hydroxybenzene with CH_2O or acetaldehyde. Vegetable tanning agents may also be added to the tanning mixt., or the components may be allowed to act on the hides in succession.

Tanning hides. B. QUENDT. Brit. 332,262, Jan. 10, 1929. Tanning of hides with vegetable substances such as quebracho ext. is promoted by a preliminary treatment with a soln. of a water-sol. non-sulfonated condensation product of an aromatic amine such as aniline or dimethylaniline with CH_2O or the like, which may be used together with alum, and NaCl or Na_2SO_4 or both. Details and examples are given.

Enzymic products. CHARLES J. M. M. LEPETIT (to Röhm & Haas Co.). U. S. 1,779,243, Oct. 21. In the production of enzymic products such as those suitable for preparing hides for tanning, a mold culture such as a culture of *Aspergillus oryzae* on bran, shorts, middlings or ground oil-meal cakes is treated with plasmolyzing and dehydrating salts such as anhyd. Na_2SO_4 (which serves as a drying agent) mixed with $NaHCO_3$ and H_3BO_3. A stable dry powder can be thus obtained.

Dressing leather. BRUNO REWALD. U. S. 1,779,012, Oct. 21. Leather is impregnated with material including a phosphatide-like material from vegetable matter, oily material and albumin, *e. g.*, a product from soy beans, train oil and various auxiliary ingredients.

Impregnating leather with rubber, etc. C. G. SHAW. Brit. 331,263, Feb. 19, 1929. Leather is impregnated with rubber cement, with or without fillers, and vulcanization is effected with S and an ultra-accelerator such as piperidine pentamethylenedithiocarbamate or Zn ethylxanthate.

Fancy leather. A. EHRENREICH and R. TANDLER. Brit. 331,241, March 26, 1929. Skins of terrestrial or marine animals having external protuberences such as shagreen are treated to fix the shagreen to the skin, as by use of tanning substances or CH_2O, and are then treated with substances such as láctic acid or HCl with addn. of salt to dissolve mineral constituents, and are finally tanned.

Cementing leather surfaces together. WILLIS A. GIBBONS (to General Rubber Co.). U. S. 1,779,808, Oct. 28. Leather surfaces are prepd. for joining with each other by treatment with artificial aq. dispersions of rubber and with NH_3.

Imitation leather (cloth coated with a nitrocellulose composition containing castor oil). IMPERIAL CHEMICAL INDUSTRIES, LTD., and H. J. TATTERSALL. Brit. 331,814, March 7, 1929. Rancidity of the castor oil is prevented by treating it with a reagent such as peracetic acid in sufficient proportion to attack the trilinolein constituent of the oil. Linseed oil, cottonseed oil and other oils also may be similarly treated; various proportions and details of coating compns. are given.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Notes from the rubber industry. T. L. GARNER. *Brit. Plastics* **2**, 125, 139 (1930).—A brief review and discussion of several recent papers. C. C. DAVIS

The coloring of rubber. F. JACOBS. *Rev. gén. caoutchouc* **7**, No. 64, 17–21(1930); cf. *C. A.* **24**, 4958, 5535.—In conclusion the use of org. colors in air bags, water bottles and other molded products, and colored hard rubber is described. C. C. DAVIS

"Cheaply black," a new, economical pigment for rubber mixtures. R. DITMAR. *Caoutchouc & gutta-percha* **27**, 15177–8(1930).—"Cheaply black" is a gray-black powder, with d. 2.2, which does not adsorb S or accelerators during vulcanization, and which can be more easily mixed than ordinary gas black. Representative formulas for various types of products are given to show the utility of this material. C. C. DAVIS

Mineral black as a reënforcing filler. PHILIP SCHIDROWITZ AND MAURICE PHILPOTT. *Kautschuk* **6**, 197–9, 204–7(1930).—Mineral blacks, which in general are obtained from slates and from fossil products contg. C., have not heretofore been used as reënforcing fillers in the rubber industry. A recently discovered mine in Devonshire, England, contains deposits of mineral black which has about 66% of mineral substances (especially clay and silica) and 33% of finely divided anthracite, and a method has been developed for refining this black to increase its C content and to render it suitable as a rubber filler. The equipment permits large-scale production of a refined black contg. approx. 66% C and 33% mineral substances. Expts. have shown that this product has considerable reënforcing action, is equal or superior to lamp black in this respect, and is about 40% as effective as the best gas blacks The tests from which these conclusions are drawn are described in detail. C. C. DAVIS

Results of a questionnaire on smoke-curing of rubber. R. G. FULLERTON. Rubber Research Inst. Malaya, *Quart. J.* **2**, No. 2, 69–100(1930).—The inquiry was conducted to obtain comparative figures of the efficiency of various types of smokehouses and of fuel consumption, the results of which are described in detail. C. C. DAVIS

Crystallized rubber. RALPH F. WOLF. *Rubber Age* (N. Y.) **28**, 79–80(1930).—Expts. on the prepn. of a cryst. rubber being carried on at the U. S. Bur. of Standards are described. Cryst. rubber has been found to consist of small transparent plates. To obtain such a product, ordinary rubber must be highly purified and then crystd. from Et_2O at a very low temp. This cryst. rubber has not been analyzed in a final way, but analyses indicate that it is not C_5H_8. Rubber can be distd. at 100° *in vacuo* with no apparent change. C. C. DAVIS

The thermodynamics of rubber. II. Temperature change of rubber under adiabatic stretching. D. S. ORNSTEIN, J. WOUDA AND J. G. EYMERS. *Rubber Chemistry & Technology* **3**, 403–8(1930).—See *C. A.* **24**, 3922. C. C. DAVIS

Compression of rubber. Some experimental results. F. JACOBS. *Rubber Age* (N. Y.) **27**, 653(1930).—English version of *C. A.* **24**, 4957. C. C. DAVIS

Service tests on rubber belts. E. G. KIMMICH. *Rubber Age* (N. Y.) **27**, 479–80 (1930).—The tests show the influence of pulley diam., tension, no. of plies, belt speeds, etc., on ply sepn. during service. C. C. DAVIS

Standardization of ozone testing. E. P. KEARSLEY. *Rubber Age* (N. Y.) **27**, 649–52 (1930).—English version of *C. A.* **24**, 4957. C. C. DAVIS

Method for preparing microsections of rubber. TRACEY F. STEELE. *Ind. Eng. Chem.*, Anal. Ed. **2**, 421–2(1930).—The method which is described and illustrated involves freezing with liquid air the specimen mounted in basswood (*Tilia americana*) Uncured and cured mixts. of all kinds except very soft ones can be readily examd. by this method. C. C. DAVIS

Hard-rubber dust, and some of its applications. FRANK BATH. *Rev. gén. caoutchouc* **7**, No. 64, 7–10(1930); cf. *C. A.* **24**, 4959.—Molds and molding problems are discussed. C. C. DAVIS

Rubber-making machinery. ANON. *Engineering* **130**, No. 3367, 95–8; No. 3369,

165–7; No. 3371, 225–7; No. 3373, 289–90(1930).—A review and discussion, illustrated with pictures and diagrams, of some of the most important modern machinery and its operation. C. C. DAVIS

Anti-friction bearings in rubber-mill equipment. W. B. MOORE. *Rubber Age* (N. Y.) **27**, 589–92(1930). C. C. DAVIS

Use of madder lake in accelerated rubber mixings. R. DITMAR AND O. FUHRMANN. *Caoutchouc & gutta-percha* **27**, 15172–3(1930).—Under proper conditions beautiful red vulcanizates can be obtained with madder lake (alizarin pptd. on Al_2O_3). In the base mixt.: pale crepe 100, S 3, ZnO 10, whiting 30, madder lake 5.44, the most attractive color in a press-cure at 152° was obtained with "Z-88" as accelerator. "Vulcafor VI" gave the next best results. With these accelerators beautiful reds were obtained. Madder lake cannot be used in S_2Cl_2 cures. C. C. DAVIS

Preservation of rubber goods by antioxidants. T. L. GARNER. *Chem. Age* (London) **23**, 252–3(1930); cf. *C. A.* **23**, 1772, 4101.—A general review. C. C. D.

Toxic substances in the rubber industry. XIII. Arsenic and its compounds. P. A. DAVIS. *Rubber Age* (N. Y.) **27**, 477–8(1930); cf. *C. A.* **24**, 4423. **XIV. Cadmium and its compounds.** *Ibid* 593–4. **XV. Ethyl acetate.** *Ibid* **28**, 27–8. C. C. DAVIS

Accelerators of vulcanization. F. JACOBS. *Caoutchouc & gutta-percha* **27**, 15165–72(1930).—The com. names, manufacturer, chem. names and formulas and the relative activities of 53 accelerators are given. C. C. DAVIS

Vulcanization accelerators. A survey of the patent literature of the last few years. I. ALADIN. *Gummi-Ztg.* **44**, 2534–5(1930). **II.** *Ibid* 2577–8. **III.** *Ibid* **45**, 15–7. IV. *Ibid* 67–8, 111–4. C. C. DAVIS

Ultra-accelerators. G. DUMONTHIER. *Rev. gén. caoutchouc* **7**, No. 64, 23–4(1930); cf. *C. A.* **24**, 3674.—Formulas are given to show the utility of tetramethylthiuram monosulfide ("Thionex") in rubber mixts. for footwear. C. C. DAVIS

The influence of zinc oxide on the action of the principal accelerators of vulcanization. The preparation of transparent vulcanized rubber. R. THIOLLET AND G. MARTIN. *Rubber Age* (N. Y.) **28**, 29–30(1930).—English version of *C. A.* **24**, 5179. C. C. DAVIS

Overflow during vulcanization, its dependence upon inactive and active fillers and errors in previous calculations on the specific gravity of vulcanizates resulting from it. RUDOLF DITMAR AND KARL H. PREUSSE. *Rubber Age* (N. Y.) **27**, 595–6(1930).—English version of *C. A.* **24**, 5180. C. C. DAVIS

Fertilizing rubber trees (BEAR) **15.** Activated ferric oxide (Brit. pat. 332,259) **18.** Rubberizing fabrics (Brit. pat. 331,594) **25.** Impregnating leather with rubber, etc. (Brit. pat. 331,263) **29.** Lining stills with rubber (Brit. pat. 331,838) **1.**

Dispersing rubber in water. WM. B. PRATT (to Dispersions Process, Inc.). U. S. 1,780,657, Nov. 4. Rubber is dissolved with NH_3 in a solvent such as C_6H_6 and the soln is mixed with water and the solvent removed by distn. to obtain a dispersion similar to latex. A stabilizer such as sulfonated castor oil may be used. Cf. *C. A.* **24**, 264.

Electrodeposition of rubber. WM. A. WILLIAMS. U. S. 1,778,841, Oct. 21. There is added to an alk. latex an electrolyte such as NH_4Cl which will not in itself readily cause coagulation but which in conjunction with suitable electrodes such as Zn and C immersed in the mixt., and directly and conductively connected with each other externally, will act as a self-excitant, setting up an electromotive force in the circuit sufficient to effect deposition of the rubber or similar material upon the anode without production of gas bubbles at the anode. Cf. *C. A.* **24**, 4665.

Electrophoretic deposition of rubber, etc. DUNLOP RUBBER CO., LTD., D. F. TWISS and R. G. JAMES. Brit. 331,563, Feb. 7, 1929. The H-ion concn. is increased in the presence of suitable protective colloids such as casein, hemoglobin, saponin, egg albumin, gelatin or licorice to such a degree that the charge on the particles is reversed without causing coagulation. A p_H of 0 to 5 may be used, and numerous details of procedure are described.

Preserving rubber. ALBERT M. CLIFFORD (to Goodyear Tire & Rubber Co.). U. S. 1,779,390, Oct. 21. Vulcanization is effected in the presence of a reaction product of piperidine and α-, β- or chloronaphthol.

Use of phenyl-α-naphthylamine to render rubber resistant to deterioration from age. JAN TEPPEMA (to Goodyear Tire & Rubber Co.). U. S. 1,781,306, Nov. 11. About 2% or less of phenyl-α-naphthylamine or a similar compd. may be added.

Continuous process of forming sponge-rubber strips. BENJAMIN B. FELIX (to Featheredge Rubber Co.). U. S. 1,780,122, Oct. 28. Mech. features.

Rubber plates containing embedded cords. HERMANN DEBOR. U. S. 1,781,370, Nov. 11. Substantially uniform pressure is applied about the entire periphery of cords to reduce their diam. to less than the normal diam. and they are then embedded in rubber.

Uniting fibrous materials with metals, etc., by use of rubber. LORIN B. SEBRELL (to Goodyear Tire & Rubber Co.). U. S. 1,781,649, Nov. 11. See Brit. 310,461 (*C. A.* **24**, 752).

Substituted thiuram polysulfides. GEORGE S. WHITBY (to Roessler & Hasslacher Chem. Co.). U. S. 1,780,545, Nov. 4. Tetraalkyl polysulfides which may be used as *accelerators in rubber vulcanization* are produced by treating salts of dialkyldithiocarbamic acid such as Na dimethyldithiocarbamate with S chloride.

Condensation products of aldehydes and amines (rubber vulcanization accelerators). IRA WILLIAMS and WALDO B. BURNETT (to E. I. du Pont de Nemours & Co.). U. S. 1,780,326, Nov. 4. Condensation products of undefined mol. structure are produced by condensation of 1 mol. proportion of an amine such as aniline, butylamine, ethylamine, *o*-tolyldiguanide, ethylaniline, ethylenediamine or the like with a plurality of mol. proportions of an aldehyde such as acetaldehyde, propionaldehyde, butyraldehyde, heptaldehyde, crotonaldehyde, citral, acetaldol or α-ethyl-β-propylacrolein, etc. Numerous examples and details of making these products are given. U. S. 1,780,334 relates to condensation of similar starting materials in the presence of acid substances.

Rubber vulcanization accelerators. I. G. FARBENIND. A.-G. Brit. 331,885, April 11, 1929. Compds. mentioned as accelerators include mixed disulfides formed from μ-benzothiazyl *p*-nitrophenyl disulfide, 4-methoxy-6-chloro-2-benzothiazyl *p*-nitrophenyl disulfide and 4,6-dichloro-2-benzothiazyl *p*-nitrophenyl disulfide, by heating together the 2 reacting materials in the presence of a solvent such as C_6H_6 or toluene.

Rubber vulcanization accelerators. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,779,715, Oct. 28. See Can. 298,698 (*C. A.* **24**, 2918).

Mold for curing rubber tires. PARRY KELLER (to Goodyear Tire & Rubber Co.). U. S. 1,781,658, Nov. 11.

Mold for vulcanizing tires. PARRY KELLER (to Goodyear Tire & Rubber Co.) U. S. 1,779,396, Oct. 21. Structural features.

Apparatus for vulcanizing tires. J. A. SPENCER-SMITH. Brit. 331,698, July 10, 1929. Structural features.

Apparatus for vulcanizing inner tire tubes. RALPH W. HUTCHENS and ARNOLD R. KRAUSE (to Gillette Rubber Co.). U. S. 1,781,393, Nov. 11. Structural features.

Apparatus for vulcanizing tire casings. WILBUR F. WIRGMAN, JR., and MOSES E. TEDROW (to Goodyear Tire & Rubber Co.). U. S. 1,779,385, Oct. 21. Structural features.

Apparatus for vulcanizing rubber soles of footwear, etc. LIVERPOOL RUBBER CO., LTD., F. AMENDE and T. R. DIBDIN. Brit. 331,187, March 20, 1929. Structural features.

Rubber vulcanization. WILLIS A. BOUGHTON. U. S. 1,781,492, Nov. 11. An ammoniacal suspension of rubber is treated with a gas comprising a hydride of an element of the "S family" the atomic wt. of which is at least as great as that of S, such as H_2S, in excess of the quantity required to react with the NH_3. This serves to form a product which may be prepd. on cloth, paper, pulp, etc., as a waterproofing, or in other forms.

Rubber vulcanization. DONALD H. POWERS (to E. I. du Pont de Nemours & Co.). U. S. 1,780,149, Oct. 28. An accelerator is prepd. by condensing 2 mols. of an aliphatic aldehyde having 7 C atoms or less such as heptaldehyde with about 2 mols. of an aliphatic amine such as methylamine and causing the resulting condensation product to react with 1–2 mols. of CH_2O while cooling to prevent overheating.

Rubber vulcanization accelerator. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,780,604, Nov. 4. Phenyl-*p*-piperidylphenylguanidine is used as an accelerator.

Vulcanizing rubber. LORIN B. SEBRELL (to Goodyear Tire & Rubber Co.). U. S. 1,779,375, Oct. 21. There is used as an accelerator a reaction product of mercaptobenzothiazole with a condensation product of a straight-chain aldehyde and an amine of the formula RNH_2 in which R is a benzene group, such as crotylideneaniline. Cf. *C. A.* **24**, 3926.

CHEMICAL ABSTRACTS

Vol. 25. JANUARY 20, 1931 No. 2

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Electrically operated water bath with extraction apparatus. A. BEHRE. *Chem.-Ztg.* **54**, 763–4(1930). J. H. MOORE

Rapid cooling device. RUDOLF KOHLMANN. *Chem.-Ztg.* **54**, 764(1930). J. H. MOORE

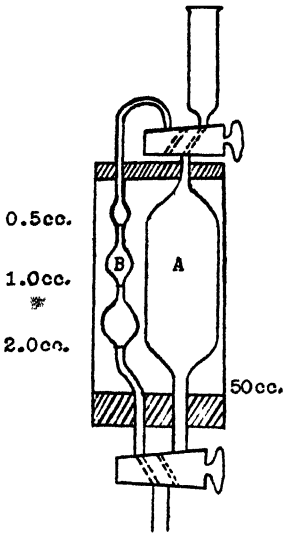
An improved Victor-Meyer molecular-weight apparatus. MILDRED M. HICKS-BRUUN. *Bur. Standards J. Research* **5**, 575–83(1930).—Berthelot's method of limiting d. is made use of in detg. the mol. wt. of hydrocarbons, eliminating to a large extent the effects of departure from the perfect gas laws. A modified Victor-Meyer mol.-wt. app. and the technic employed in its use are described. The modification avoids the difficulties of local temp. differences and permits measurements at 2 pressures, 1 atm. and 0.5 atm. Expts. with hydrocarbons gave mol. wts. differing from the theoretical by the following deviations: benzene, 0.2%; hexane, 0.24%; naphthalene, 0.06%. ALLEN S. SMITH

Cock without packing-gland for the acid industry. HEINRICH OEITINGER. *Chem. Fabrik* 1930, 486.—The cock is made of "Antacid" and the construction is similar to that of stoneware cocks. J. H. MOORE

A form of condenser for use with high-boiling point liquids. GEORGE W. MCCREA. *J. Chem. Education* **7**, 2963–5(1930). E. H.

A condenser for low-temperature evaporation of water. H. M. EVANS, R. E. CORNISH AND J. C. ATKINSON. *J. Am. Chem. Soc.* **52**, 4334–5(1930).—An app. is described in which H_2O may be distd. at about 7°. J. H. MOORE

A design of metal x-ray tube. N. S. GINGRICH. *Rev. Sci. Instruments* **1**, 691–3 (1930). E. H.



A vacuum-tube potentiometer applicable for use with glass electrodes of high resistance. DELAFIELD DUBOIS. *J. Biol. Chem.* **88**, 729–41(1930).—A modification of Stadie's potentiometer (*C. A.* **23**, 4598) is described, a screen-grid vacuum tube at low grid voltage being used. Drifts of potential do not occur with this set-up. K. V. T.

Combined use of the photoelectric cell and projection microscope. ALFRED SAVAGE AND M. C. JAMIESON. *Can. J Research* **3**, 322–26(1930).—The combined use of a projection microscope, a red dye (fuchsin) and a photoelec. cell insensitive to red light to measure rapidly the size of cells is described. Colored cells (uredospores of *Puccinia gramivis* and red blood cells), interposed between the incident light and the photoelec. cell, affected the illumination in proportion to the size of the cell and intensity of the stain. The photoelec. current was found to be inversely proportional to the sizes of the images and at low magnification was measured by the deflections of a sensitive galvanometer. J. W. SHIPLEY

A new apparatus for electrometric volumetric analysis with electron tubes. E. BERL, W. HERBERT AND W. WAHLIG. *Chem. Fabrik* 1930, 445–6, 458–60.—A description of an app. designed by the authors, with operating directions and 6 references. J. H. MOORE

Determination of carbon and hydrogen. EDGAR STANSFIELD AND JOHN W. SUTHERLAND. *Can. J. Research* **3**, 318–21(1930).—The authors describe a combustion tube modified to secure complete combustion of coal with the least liability to error. The combustion tube can be easily emptied, cleaned and repacked and because none of the reagents comes in contact with the walls of the tube it has, with reasonable care, a long life. CuO and contact Pt are used, the former in a porcelain boat. An electrically, internally heated quartz tube is used instead of the customary CuO diffusion spiral. A thermocouple is permanently installed in the transparent quartz tube, thereby insuring accurate temp. control. The paper includes a diagram of the combustion tube accompanied by a full description of its operation. It may be used for the detn. of H_2 and O_2 in any org. material. J. W. SHIPLEY

A new form of apparatus for determination of gases by manometric measurement. HSIEN WU. *Proc. Soc. Exptl. Biol. Med.* 27, 883–5(1930).—The apparatus (Fig. 1) differs from that of Van Slyke (cf. *C. A.* 18, 3615) in that 2 chambers are used, one for the extn., the other for measuring the gas. It is used essentially in the same way as the Van Slyke app. It is superior in that the measuring chamber is always clean, the calibration is more accurate, the gas as repeatedly extd. is stored in chamber *B* and the total vol. ascertained at one reading, fractional analyses of the extd. gas can be done by absorbing with various reagents in chamber *A* and the residual gas measured in *B*, the vacuum reading for the same kind of soln. is const., irrespective of the vol. used for extn. C. V. BAILEY

The measurement of a rapidly fluctuating flow of gas. J. S. KING AND B. H. WILLIAMS. *Dept. Sci. Ind. Research, Fuel Research Tech. Paper* No. 27, 18 pp.(1930).—Full details, with cuts and charts, of the construction, calibration and operation of a *device* for photographically recording the flow of *water-gas* made, and the air supplied during the blow, based on the pressure drop across an orifice. The method is quite simple and the results seem satisfactory. J. H. MOORE

Differential ebullioscope provided with a dephlegmator and its application. W. SWIETOSLAWSKI. *Roczniki Chem.* 10, 570–8(578 French)(1930).—A differential ebullioscope with a dephlegmator is described suitable for the study of the purity of single liquids as well as azeotropic and eutectic substances. The same app. is modified for the study of small quantities of liquids. An arrangement for the regulation of filling the ebullioscope is outlined. The ebullioscope is used for the study of ebullition temp. t_H and condensation temp. t_B of a substance. If the liquid (single, azeotropic or eutectic substance) does not contain any impurities, both temps. t_H and t_B are identical. On the other side, a difference $\Delta t > 0$ is observed when the liquid contains impurities. Several substances were examd.: 3 samples of MeOH (Poulenc, Riedel-de Haën, synthetic), benzene (Merck), toluene (Merck, for ebullioscopic investigations), CS_2. In all cases studied the difference Δt was greater than 0, except with C_6H_6 and CS_2. An example of detn. of the quantity of H_2O in the azeotropic Me_2CO-CS_2 is also cited. J. KUČERA

Apparatus for the determination aboard ship of the salinity of sea water by the electrical conductivity method. FRANK WENNER, EDWARD H. SMITH AND FLOYD M. SOULE. *Bur. Standards J. Research* 5, 711-32(1930).—An elec. salinity bridge is described which furnishes a convenient means for the detn. of the salinity of samples of sea water as they may be collected. The app. consists essentially of a Wheatstone bridge, cond. cells adapted to filling and emptying without removal from the thermostat, and measuring instruments, all built into a single cabinet suited to severe sea conditions. Effects of polarization and differences in temp. coeff. are reduced by using 2 similar cells filled with sea water in adjacent arms of the bridge. A supply of standard sea water was used for frequent standardization. Three sets of equipment have been built and used on various expeditions with satisfactory results. The instrument compares well in performance with titration measurements, is capable of individual measurements accurate to within 0.02% and is well adapted to the measurement of total salt. ALLEN S. SMITH

Electric tube furnace for laboratory use, especially for microelementary analysis. P. A. THIESSEN. *Chem. Fabrik* 1930, 493–5.—The refractory tube of Al silicate, or other material, has parallel channels lengthwise in the inner wall, open on the inside and contg. the spiral heating wires. The heat is thus radiated directly on the combustion tube instead of being transmitted through the refractory tube. Operating directions for microanalyses and other uses are given, with 7 references. J. H. MOORE

A microfurnace for temperatures above 1000°. H. S. ROBERTS AND G. W. MOREY. *Rev. Sci. Instruments* 1, 576–80(1930).—The accuracy and limitations of the microfurnace as a tool for the investigation of phase relations and m. p. at high temps. are discussed. The furnace consists essentially of a strip of platin-rhodium bent in the form of a U. A source of const. current is described. The 2 major sources of error in measuring the temp. of a substance on the strip, which may be minimized by calibration, are (1) differences in temp. between top and bottom of the charge and (2) uncertainties in

the detn. of the true temp. of the strip. The upper limit for a single strip is about 1850°. The lower limit is that of the optical pyrometer. Readings at sharp m. p. were duplicated within 10° at temps. above 1400°. ALLEN S. SMITH

A simple substitute for a Kipp generator. FRANK LANE. *J. Chem. Education* **7**, 2583(1930).—The app. is quickly made from 2 wide-mouth bottles and glass tubing. J. H. MOORE

Another hydrogen sulfide generator. W. A. MANUEL. *J. Chem. Education* **7**, 2608(1930).—The app. is made from two 250-cc. leveling bulbs connected with rubber tubing. J. H. MOORE

Maintenance of a standard of electromotive force: Notes on standard Weston cells. A. NORMAN SHAW AND H. E. REILLEY. *Can. J. Research* **3**, 473–89(1930).—A detailed procedure for the maintenance of a standard of voltage to within 1 or 2 parts in a million is described. A summary of data on standard cells is included. J. W. S.

Apparatus for determining tendency of coal and other materials for spontaneous combustion (KREULEN) **21.** Self-carbureting of industrial gases from brown coals (FREUND, BECKER) **21.** Gas generator and burner suitable for utilizing liquid fuels (U. S. pat. 1,783,564) **21.**

Rotary filter. EDWARD W. W. KEENE. U. S. 1,783,937, Dec. 2.

Air filter. MASCHINEN- UND WERKZEUGFABRIK KABEL VOGEL & SCHEMMANN. Ger. 506,488, Nov. 22, 1929. Means is described for joining a no. of filter plates in zig-zag fashion, so as to form pockets.

Apparatus for filtering air and other gases. FRIEDRICH CLASEN and HEINRICH LENCKERSTORF (to Maschinenfabrik Beth, A.-G.). U. S. 1,784,339, Dec. 9. Structural features.

Bag filter for filtering air or other gases. I. L. BRAMWELL, C. W. H. HOLMES and BIRTLEY IRON CO., LTD. Brit. 332,601, Jan. 23, 1929. Structural features.

Filter suitable for treating gases or vapors. ALBERT SCHREMPP. U. S. 1,783,143, Nov. 25.

Automatic resistance-controlled air and gas filter. HANS E. BIRKHOLZ (to American Air Filter Co.). U. S. 1,783,181, Dec. 2. Structural features.

Air-cleaning device (suitable for use on automobiles). HERMAN B. ANGLEMEYER. U. S. 1,781,742, Nov. 18. Structural details.

Apparatus for cleaning air-filter cells. JOHN R. MCCONNELL and ALBERT S. LEWIS, JR. (to American Air Filter Co.). U. S. 1,783,194, Dec. 2. Structural features.

System of material circulation through associated filter units, to effect filtration and cleaning of the filters. LEWIS L. DOLLINGER (to Staynew Filter Corp.). U. S. 1,784,278, Dec. 9. Various details of filter construction and operation are described.

Filter-sand washing apparatus. MORRIS L. BAYARD and MINOR HARVEY. U. S. 1,784,798, Dec. 9. Structural features.

Liquefaction and rectification system for separating constituents of gaseous mixtures such as air. CLAUDE C. VAN NUYS and JOSEPH L. SCHLITT (to Air Reduction Co.). U. S. 1,784,120, Dec. 9. App. and various details of procedure are described.

Apparatus for separating entrained particles from gases. FRIEDRICH EICKHOLT. U. S. 1,784,664, Dec. 9. Structural features.

Apparatus for separating solid particles from gas streams. WALTER M. COOK (to International Combustion Engineering Corp.). U. S. 1,783,357, Dec. 2. Structural features.

Filter for cleaning fluids such as naphtha. PAUL W. MORGAN (to Morgan Cleaners Equipment Co.). U. S. 1,783,444, Dec. 2. Structural features.

Continuous-pressure filter and cake-discharging apparatus. JASPER A. MCCASKELL. U. S. 1,784,372, Dec. 9. Structural features.

Apparatus for degasifying liquids, particularly liquid fuels. ALFRED LANSER. Ger. 506,040, Apr. 11, 1928.

Apparatus for separating entrained liquid from vapors such as produced in concentrating juice or sirup. JAMES HAMILL. U. S. 1,784,627, Dec. 9. Structural features.

Apparatus for gravity separation and recovery of oils and grease from garage waste, etc. W. G. MORSE. Brit. 332,569, Feb. 23, 1929. Structural features of an app which may be steam heated.

Apparatus for separating lump materials of different electric conductivities. BARTHEL GRANIGG. Ger. 494,092, Feb. 9, 1927.

; gravity.
B. L. BOURKE and BIRTLEY IRON CO., LTD. Brit. 332,583, Jan. 23, 19 Structural features.

Apparatus for separating materials of different specific gravities such as minerals by the action of vibration and air currents. KENNETH DAVIS (to Peale-Davis Co.). U. S. 1,782,391–2, Nov. 18. Structural features.

Helical mixing apparatus for liquids. MASCHINENFABRIK AUGSBURG-NÜRNBERG A.-G. Ger. 504,629, June 14, 1929.

Apparatus for indicating mean temperature. MARSHALL TAYLOR. U. S. 1,782,106, Nov. 18.

Heat indicator suitable for use with engine-cooling systems. HERMAN SCHLAICH. U. S. 1,784,756, Dec. 9. Various details are described of a device, the temp.-responsive element of which may be inserted in the hose of an internal-combustion engine-cooling system.

Photoelectric cell. SOC. DES USINES CHIMIQUES RHÔNE-POULENC. Brit. 332,733, July 12, 1929. The cathode and an auxiliary electrode may consist of K deposited on supports or on a glass envelope, with a filling of A at low pressure. Various details of operation are described.

Electric discharge devices. A. A. J. CROWNE. Brit. 332,734. July 4, 1929. A cathode is used comprising a radio-active substance such as U and a photoelec. substance such as Rb or K. Various details of manuf. and operation are described.

Electric discharge devices. M-O VALVE CO., LTD., and D. A. RANKIN. Brit. 332,695, June 12, 1929. For producing a high thermionic emission characteristic without increasing the thermal emissivity, cathodes with a core such as W wire are provided with a white coating produced by applying a white oxide of a volatile metal such as ZnO which is afterward subjected to the vapor of an alk. earth metal such as Ba (which may be produced in the valve by decompg. Ba azide by heating) so that part at least of the oxide is reduced (the reduced Zn being evapd.).

Apparatus for freezing ice cream, egg yolks and whites, processing oils, salves, confections, etc. CLARENCE W. VOGT (to Vogt Instant Freezers, Inc.). U. S. 1,783,864–5–6–7, Dec. 2.

Indicating variations in density of gases. HERBERT H. DOW (to Dow Chemical Co.). U. S. 1,782,032, Nov. 18. Alternating opposing blasts of the gas under test and of another gas of substantially constant d. are directed on a device such as a bladed rotor movable in either direction, so that the movement of this device indicates the d. of the gas undergoing test. Various details of app. are described.

Gas-storage cylinders (for holding gas under pressure). CHESTERFIELD TUBE CO., LTD., and S. B. N. HILL. Brit. 332,556, April 22, 1929. Structural features.

Alarm device for operating a signal on the escape of poisonous or explosive gases such as illuminating gas. ANDERS H. OLSSON and PER D. PETERSON. U. S. 1,783,974, Dec. 9.

Tower and plate apparatus for contact of liquid and gas such as in gas scrubbing or absorption. FREDERICK H. WAGNER (to Bartlett Hayward Co.). U. S. 1,782,862, Nov. 25. Structural features.

Apparatus for degasifying liquids such as oils and fluid insulating materials, by spraying in vacuum. SOCIETÀ ITALIANA PIRELLI and L. EMANUELI. Brit. 332,542, April 19, 1929. Structural features.

Combined spray-drying and gas-combustion apparatus. INGENUIN HECHENBLEIKNER (to Chemical Construction Corp.). U. S. 1,782,822, Nov. 25. A spray-drying chamber with an apertured upper wall carries a superposed combustion chamber for generating and supplying hot gases to the drying chamber through the apertured upper wall of the latter. Various details of construction are described.

Apparatus for spray-desiccation of liquids or similar operations. BEN F. UHL (Industrial Spray-Drying Corp.). U. S. 1,782,054, Nov. 18. Various details of app. and mode of operation are described.

Evaporating apparatus suitable for liquids. HARLAN W. HOW (to Buffalo Foundry & Machine Co.). U. S. 1,782,143, Nov. 18. Structural features.

Bone-char-drying apparatus. JAMES HAMILL and JOHN F. TADDIKEN. U. S. 1,784,626, Dec. 9. Structural features.

Drying tunnel and apparatus for passing materials through the tunnel. ALLGEMEINE ELEKTRIZITÄTS-GES. (to International General Electric Co.). Brit. 332,491, Nov. 3, 1928. Mech. and elec. control devices are described.

Storage vessel for viscose and like masses. WOLFF & Co. KOMM.-GES. AUF [illegible] and WILHELM NASCHOLD. Ger. 506,147, Aug. 22, 1929.

Bin and hopper suitable for feeding powdered or lump chemicals. ELMER E. HARPER. U. S. 1,783,423, Dec. 2.

Apparatus suitable for various chemical or evaporating operations. FRANZ LAPPE, EDWIN KOCH, MATHIAS PIER and HANS SAUER (to I. G. Farbenind. A.-G.). U. S. 1,783,726, Dec. 2. The app. is formed of iron which has been treated at high temps., and under conditions precluding oxidation, with a gas (such as H at 900°) capable of forming gaseous compds. with the impurities such as O, S and C originally present in the metal (this treatment rendering the iron resistant to corrosion).

Optical system for illuminating opaque objects for microscopic examination. HARRY S. GEORGE (to Electro Metallurgical Co.). U. S. 1,784,425, Dec. 9.

Crucibles. WILLIS R. WHITNEY (to General Elec. Co.). U. S. 1,784,647, Dec. 9. In making crucibles, suitable for elec. induction furnaces, having an inner heating resistor and an outer heat refractory layer, the crucible is molded from a mixt. of heat-refractory material such as fireclay and powd. resistance-heating material such as graphite and the resistance-heating material is then burned out of an outer layer of the heat refractory material so as to leave an inner heating resistor.

Oil- or coal-fired tilting crucible furnace. J. W. PENICUD. Brit. 332,701, June 17, 1929.

Double-walled rotary muffle furnace. "SACHTLEBEN" A.-G. FÜR BERGBAU UND CHEM. IND. (Johann Küppers, inventor). Ger. 506,145, Mar. 25, 1926.

Stack recuperator suitable for use with open-hearth furnaces. WALTER J. KELLY, MILTON P. BURNS and ARCHIE BARR. U. S. 1,782,430, Nov. 25. Structural features.

Regenerative heating and smelting furnace, fired with coal dust. FRIEDRICH SIEMENS A.-G. Ger. 506,353, Mar. 2, 1927.

Sealing means for rotary tube furnaces, etc., rotating in a stationary casing. FRIED. KRUPP GRUSONWERK A.-G. Ger. 489,486, May 21, 1927. Addn. to 464,675.

Change-over valve for regenerative furnaces. MAX SCHNURPFEIL. Ger. 506,187, July 6, 1929.

Combustion chamber for pulverulent fuels. WILFRED R. WOOD. Ger. 506,462, Dec. 3, 1925. This corresponds to Brit. 253,895.

Burner with internal combustion chamber for a gas-heated annealing furnace. MAX NUSS. Ger. 504,733, Apr. 1, 1926.

Under-blast traveling grate. L. & C. STEINMÜLLER. Ger. 506,461, Aug. 25, 1928.

Device for air-cooling furnace grates. ALEXEJ LOMSCHAKOFF and PETER DMITREVSKI. Austrian 119,137, Apr. 15, 1930.

Rotary kiln. E. G. STONE. Brit. 332,761, Aug. 6, 1929.

Revolving tube kiln cooler. SOCIÉTÉ D'EXPLOITATION DES PROCÉDÉS INDUSTRIELS CANDLOT. Ger. 504,585, Nov. 3, 1929. Addn. to 483,687.

Tunnel kiln suitable for use with oil or gas burners. H. M. ROBERTSON. Brit. 332,619, Jan. 23, 1929.

Gas burner. HERRY E. KERR (to Barber Gas Burner Co.). U. S. 1,781,784–5, Nov. 18.

Gas burner. FREDERICK H. WILLCOX and EDGAR P. EVERHARD (to Freyn Engineering Co.). U. S. 1,781,796, Nov. 18.

Gas burner for furnaces. JOSEPH L. GIACOMINO (to Carl W. Gibson). U. S. 1,782,683, Nov. 25.

Gas burner. GARNET W. MCKEE. U. S. 1,783,195, Dec. 2.

Portable heat-exchange device suitable for use as a heater or cooler. JEAN B. D. L. CHARDARD (to Risler Corp. of America). U. S. 1,783,355, Dec. 2. Structural features.

Heat-exchange apparatus suitable for conditioning air. FRANK BATTER. U. S. 1,781,913, Nov. 18.

Heat-exchange apparatus for use with sulfurous gases, etc. HENRY F. MERRIAM (to General Chemical Co.). U. S. 1,782,435, Nov. 25. Structural features.

Heat-exchange apparatus suitable for cooling oils with water or for various other purposes. STANLEY J. CHUTE (to Griscom-Russell Co.). U. S. 1,782,409, Nov. 25. Structural features.

Pressure-relieving apparatus for autoclaves. THOMAS GRISWOLD, JR. (to Dow Chemical Co.). U. S. 1,783,163, Nov. 25.

Condenser suitable for use in the production of mercury. EMANUEL W. HARTMAN. U. S. 1,783,286, Dec. 2. Structural features.

Acetylene generator. EWALD LÜTSCHEN. Ger. 504,547, Jun. 15, 1926. Details of construction.

Acetylene generators. JACOB KNAPPICH. Ger. 504,776, Feb. 19, 1929. To prevent piling and clogging of the spent CaC_2, the water container is provided with 2 staggered endless conveyors which catch the CaC_2 and finally drop it on an inclined plate leading to a lower receptacle.

Thermostatic electric switch. HOWARD D. MATTHEWS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,783,179, Dec. 2. Structural features.

Thermostatic control for electric apparatus. EDWIN A. RUTENBER (to A. J. Lindemann & Hoverson Co.). U. S. 1,783,309, Dec. 2.

Thermostatic device suitable for use with various apparatus. MAX MASON (30% to Louis B. Slichter, 30% to Donald L. Hay and 10% to Donald C. Slichter). U. S. 1,782,045, Nov. 18. Structural features.

Thermostatic control for ovens heated by gas or electricity. ARTHUR W. WALKER. U. S. 1,783,320, Dec. 2. Structural features.

Thermostat suitable for operating dampers, etc. JAMES J. LAWLER. U. S. 1,783,574, Dec. 2. Structural features.

Thermostatic control device for heating systems. FRED I. RAYMOND. U. S. 1,784,538, Dec. 9. Structural features.

Thermostatic valve-control device. WM. F. SEARLE, JR. (to Fulton Sylphon Co.). U. S. 1,784,077, Dec. 9. Structural features.

Thermostatic valve-control device. JAMES J. LAWLER. U. S. 1,784,734, Dec. 9. Structural features.

Thermostatic valve. EDGAR J. LEACH (to Time-O-Stat Controls Co.). U. S. 1,783,730, Dec. 2.

Thermostatic valve. WM. W. CARSON, JR. (to Fulton Sylphon Co.). U. S. 1,784,041-2, Dec. 9.

Thermostat. THOMAS R. CLARK (to Fulton Sylphon Co.). U. S. 1,784,045, Dec. 9.

Thermostatic valve. JEAN V. GIESLER (to Fulton Sylphon Co.). U. S. 1,784,053-4-5 and U. S. 1,784,057-8-9-60-1-2-3, Dec. 9.

Thermostatic valve. JEAN V. GIESLER, WM. W. CARSON, JR., and THOMAS R CLARK (to Fulton Sylphon Co.). U. S. 1,784,056, Dec. 9.

The photochemical primary process. H. SPONER. *Z. angew. Chem.* **43**, 823–30 (1930).—A review with a tabulation of spectroscopically detd. heats of dissocn. C. E. P. JEFFREYS

Selective solubility of hydrocarbons in aniline. YA. KHISIN. *Neftyanoe Khozyaistvo* **18**, 996–9(1930).—Extn. with aniline removes C_6H_6 or unsatd. hydrocarbons completely from their mixts. with synthetic satd. hydrocarbons. Only half the naphthenes are removed from their mixt. with satd. hydrocarbons even after 10 extns. with equal vols. of aniline. A. A. BOEHTLINGK

Proof of the impossibility of spontaneous magnetization. A remark on the theory of Weiss-Heisenberg. N. S. AKULOV. *Z. Physik* **64**, 559–62(1930).—If spontaneous magnetization existed, reversing the sense of magnetization in the direction of highest magnetizability in a single crystal of Fe would cause the magnetic vector to pass through directions of higher magnetic energy. This energy difference is much larger than the energy losses due to hysteresis, which is vanishingly small for pure Fe. E. B.

Theory the magnetization curve. II. The magnetization of nickel wire under strong tension. R. BECKER AND M. KERSTEN. *Z. Physik* **64**, 660–81(1930).—A corrected formula is derived on the bases of the theory previously advanced (*C. A.* **24**, 5191) for the energy of a distorted cubic lattice and the curve of magnetization as function of the tension. The applied magnetic field is obtained. For high tension Z, the field necessary to produce magnetic satn. is proportional to Z and the magnetostriction is $^3/_2$ times larger than for metal free from tension. Expts. support these conclusions. EGON BRETSCHER

The magnetic characteristic of iron crystals. WALTHER GERLACH. *Z. Physik* 64, 502–6(1930).—The coercive force of single crystals of Fe vanishes if the crystals are chemically and physically pure (free from internal tension). The energy losses on magnetization, resulting from hysteresis, disappear completely. EGON BRETSCHER

The variation of resistance of thin layers of bismuth in a magnetic field. FRIEDRICH GROSS. *Z. Physik* **64**, 520–36(1930).—The variation of the resistance of thin layers of Bi (up to 6μ thick) in a magnetic field depends upon the method of its prepn. To obtain high sensitivity, the Bi is sublimed *in vacuo* on a film of glass which is kept just below 270° (m. p. of Bi). The variation of resistance amounts in this case to 90% in a field of 28,300 gausses. Low sensitivity is caused by gas occlusion. The Bi layers thus obtained are always cryst. (sometimes orientated) as shown by x-ray reflection. E. B.

The structure of thin layers of bismuth. WILHELM BÜSSEM, FRIEDRICH GROSS AND KARL HERRMANN. *Z. Physik* **64**, 537–46(1930); cf. preceding abstr.—Bright thin layers of Bi consist of crystallites which are orientated (fiber structure); the gray modification contains the crystals in random orientation. The lattice is rhombic and possesses the same parameters as ordinary Bi. EGON BRETSCHER

A new phenomenon in the change of resistance in a magnetic field of single crystals of bismuth. L. SHUBNIKOW AND W. J. DE HAAS. *Nature* **126**, 500(1930); cf. *C. A.* 24, 4435, 4678–9. ARTHUR FLEISCHER

A simple, accurate method for measuring the diamagnetic susceptibility of dissolved substances. SIMON FREED AND CHARLES KASPER. *Phys. Rev.* **36**, 1002–4(1930).—A very accurate quasi-null method is described. Independent runs with NaI soln. agreed within ±0.06%. BERNARD LEWIS

The dielectric constant of gaseous hydrogen cyanide and its dipole moment.

KARL FREDENHAGEN AND FRITZ MASKE. *Z. physik. Chem.*, Abt. B, **10**, 142–8(1930).—The dielec. const. of vapor from liquid HCN held between 3° and 15°, superheated to 30–200° was measured. The condenser was built within a glass tube, and the whole was inserted in an oven and submitted to high-frequency e. m. f. The results are given graphically and the dipole moment is calcd. as 2.1×10^{-18} e. s. u. G. M. EVANS

Dipole moments of the *o*-dihalobenzenes. ERNST BERGMANN, LEO ENGEL AND STEFAN SANDOR. *Z. physik. Chem.*, Abt. B, **10**, 106–20(1930).—The moments of all 10 *o*-dihalo- and the 4 monohalobenzenes are calcd. These are carefully compared with values of other investigators and those from x-ray investigations. An increase over the normal 60° angle between the halogens is found in the *o*-compds. This increase amounts to 9° in the difluoro- and increases to over 37° in the diiodobenzenes. GREGG M. EVANS

Ultrasonic velocity and absorption in oxygen. W. H. PIELEMEIER. *Phys. Rev.* **36**, 1005–7(1930). BERNARD LEWIS

Specific-heat charts for gases. A. C. HALFERDAHL. *Chem. & Met. Eng.* **37**, 686–7(1930). E. H.

Note on the pressure variation of specific heats of gases derived from compressibility data. L. G. HOXTON. *Phys. Rev.* **36**, 1091–5(1930).—The rate of variation of c_p with pressure at const. temp. calcd. from p-v-T data is compared with the rate of variation detd. by direct expt. in the cases of O_2 and air over a pressure range of 20 to 100 atm. at 26°. The calcd. rates are of the same order of magnitude as the exptl. but are sensitive to methods of handling the equations of state and the variation in the coeffs. of the latter. Conclusion: The rates cannot be calcd. as accurately as they can be measured directly. BERNARD LEWIS

A new method of measuring the variation of the specific heats (c_p) of gases with pressure. E. J. WORKMAN. *Phys. Rev.* **36**, 1183–90(1930).—A method is described in which the ratio of c_p at a high pressure to c_p for the same gas at a pressure of 1 atm. is detd. The method is based upon the continuous-flow principle and avoids the necessity of measuring gas flow and heat input. Measurements were made with com. O_2 at a mean temp. of 26° and at pressures ranging from 15 to 100 atms. B. L.

The thermodynamic treatment of chemical equilibria in systems composed of real gases. II. A relation for the heat of reaction applied to the ammonia synthesis reaction. The energy and entropy constants for ammonia. LOUIS J. GILLESPIE AND JAMES A. BEATTIE. *Phys. Rev.* **36**, 1008–13(1930); cf. *C. A.* **24**, 5593 and following abstr.—The energy const. and entropy calcd. from data on the NH_3 synthesis equil. are, resp., —10058.1 $Cal._{15}$ per mole and —16.6491 $Cal._{15}$ per degree per mole. Values are given for the usual thermodynamic function at 0° and 1 atm. in the system of H_2, N_2 and NH_3. A rational and simple relation is given for the variation of ΔH with both pressure and temp., and the heat absorbed in a chem. reaction at const. pressure in systems composed of real gases. Values of the heat are computed for several pressures and temps. for the NH_3 synthesis reaction. BERNARD LEWIS

The thermodynamic treatment of chemical equilibria in systems composed of real gases. III. Mass-action effects. The optimum hydrogen : nitrogen ratio for ammonia formation in the Haber equilibrium. LOUIS J. GILLESPIE AND JAMES A. BEATTIE. *J. Am. Chem. Soc.* **52**, 4239–46(1930); cf. preceding abstr.—By means of equations previously developed, the optimum initial and equil. ratios of H_2 to N_2 for NH_3 formation at 500° at pressures up to 1000 atm. are calcd. Although the optimum equil. ratio is as low as 2.68 at 1000 atm. with no A present, the % NH_3 at this optimum ratio exceeds that at the ratio 3 by less than 0.1%. At all pressures, the yield when pure N_2 is used is about 0.6% greater than when atm. (A-contg.) N_2 is used. ELLIOTT J. ROBERTS

Studies in intensive drying. E. JUANITA GREER. *J. Am. Chem. Soc.* **52**, 4191–4201(1930).—Expts. show that C_6H_6 dried 3 years with P_2O_5 in a fused glass app. shows no change in vapor pressure with respect to normal C_6H_6 in same app. C_6H_6, CCl_4 and CS_2 dried with activated SiO_2 gel show vapor pressure decreases in 24 hrs. comparable with results of others on these intensively dried liquids. Evidence supports the theory that vapor pressure decreases are due to removal of traces of H_2O in normal liquids. Calcn. from soly. data shows that the partial pressure of H_2O in C_6H_6 deviates greatly from Raoult's law. Partial pressures of H_2O in C_6H_6 at 20.89° were measured. S. L.

Thermal conductivity of liquids. J. F. DOWNIE SMITH. *Ind. Eng. Chem.* 22, 1246–51(1930).—A general equation for thermal cond. of electrically non-conducting liquids is derived from the following data on thermal cond.: 95 and 98% EtOH at 30°, CO_2, $C_6H_5CH_3$ and isoamyl alc. at 30° and 75°, 4 kinds of hydrocarbon oil at 30°, 75° and X. °, isopropyl alc., C_6H_6, *p*-cymene, *n*-hexane and *n*-octane at 30° and 60°. The app. Bridgman's concentric cylinders (*C. A.* **18**, 1227). L. P. HALL

Dynamic azeotropism. GEORGETTE SCHOULS. *Bull. sci. acad. roy. Belg.* [5], 16, 628–45(1930).—Math. treatment of irreversible distn. of liquids based on de Donder's work on affinity. Two-phase, liquid–gas systems of 1 or 2 components are considered. The subjects discussed include distn. of pure substances and mixts., generalization of the Duhem-Margules equation, heat of reaction, azeotropic equil. and dynamic azeotropism.
G. M. MURPHY

Investigation of the structure of organic liquids in the interior and on the surface. J. J. TRILLAT. *Z. Physik* 64, 191–213(1930); cf. *C. A.* 24, 5234.—A thin film of the liquid was irradiated with Cu K_α radiation and the scattered x-rays were received on a photographic plate. Tension was 27,500 v., current 10 ma., time of exposure 1 hr. The compds. studied were homologous series of *fatty acids* and *alcs.* and some *triglycerides*. To study the surface orientation of the mols., the beam of x-rays touched tangentially the surface of a drop of the liquid. *Results. I. Interior structure of liquids.*—A large intensive ring corresponding to a period of intensity of 4–4.6 A. U. is always found in first and in some cases even in second order. It is attributed to the cross dimension of the mols. The inner ring must be due to the longitudinal dimension of the C chain as it varies with the no. of C atoms belonging to it. A continuous ground which spreads from the center of the plate and corresponds to a variable distance of the scattering elements is attributed to assocn. It is especially pronounced in the lower fatty acids and alcs., less so for the higher members and the triglycerides. *II. Surface structure of liquids.*—The aliphatic acids with the C atoms C_{10}, C_{12}, C_{14} and the alcs. C_9 and C_{11}, C_{10} and C_{12} are oriented in the surface of the liquid. The increase of length of the C chain per atom is about 1 A. U.
EGON BRETSCHER

The uniaxial direction of crystalline liquids. D. VORLÄNDER AND JOSEF FISCHER. *Ber.* 63B, 2506–10(1930); cf. *C. A.* 24, 4198.—About 21 prepns. out of 110 formed cryst. liquid layers, uniaxially directed and optically pos. The mol. structure, monotropy, enantiotropy and extent of the liquid seem to be of little importance. The more important factors are: presence of decompn. products, surface of the glass, temp. and viscosity. Whether the cryst. liquid layers grow out of the amorphous melt on cooling or on warming from the crystals is of importance. α-Anisalaminonaphthalene-α'-azobenzoic acid ester III exhibits a new phenomenon, forming an undercooled resin-like conglomerate, which may be called a cryst. solid optically anisotropic glass. M. E. L.

New observations on quartz. R. WEIL. *Compt. rend.* 191, 380–2(1930); cf. *C. A.* 24, 5002.—Most quartz crystals have birefringent regions revolving about a binary axis. This birefringence causes tiny parallel lines to show on the non-adjacent faces. When crystals are etched with HF, numerous tiny canals form which are oriented the same as the markings on the birefringent regions. AMY LEVESCONTE

The mosaic structure of crystals. F. ZWICKY. *Helv. Phys. Acta.* 3, 269–98 (1930); cf. *C. A.* 24, 1005, 3410.—The properties of a crystal are divided into 2 classes, those that depend only on the type of crystal lattice (d., sp. heat, coeff. of expansion, compressibility) and those that are detd. mainly by the grosser structure of the crystal (tensile and dielec. strength, ion cond., limit of elasticity). The theory of accidental microscopic cracks is rejected and replaced by the suggestion of a superstructure (mosaic structure), *i. e.*, a periodic variation of d. It is shown by calcn. (especially for a heteropolar crystal of the cubic system) that a crystal with superstructure possesses a lower energy than an ideal one, if cross contraction is taken into account and the polarizability of its constituents is sufficiently great. The period of superstructure of NaCl is found to be about 20 lattice consts. (110 A. U.). If the building atoms are not centrosymmetrical, a superstructure of a second type may be expected. The weak asymmetry of complex at. systems, in general, is pointed out, if the partners possess an asymmetry themselves (*e. g.*, asymmetric form of the water mol.) and the existence of monomol. films (acetic acid on a water surface) on a liquid is explained in these terms. E. B.

X-ray investigation of manganese. EINAR ÖHMAN. *Svensk Kem. Tids.* 42, 210–6(1930).—The cube edge of α-Mn measures 8.894 ± 0.005 A. U. and β-Mn, 6.300 ± 0.003 A. U. The spectrographs of α and β do not interfere with one another.
A. R. ROSE

X-ray investigations of modifications of manganese. EINAR ÖHMAN. *Metallwirtschaft* 9, 825–7(1930).—X-ray crystal structure evidence for the existence of α-, β- and γ-manganese is reviewed. X-ray photographs and tables of the angles of diffracted lines are given for α- and β-manganese. MALCOLM DOLE

Measurements with the help of liquid helium. X. Electric resistance of some alloys. W. MEISSNER. *Z. Physik* 64, 581–3(1930); cf. *C. A.* 24, 5565.—The resistance of Seemans' (*C. A.* 24, 5196) Cu-Au and Ni-Mn alloys was detd. as a function of the temp. EGON BRETSCHER

The variation of the electric conductivity of platinum on degassing in high vacuum and charging with hydrogen. KLARA WEIL. *Z. Physik* **64**, 237–47(1930).—The resistance of Pt increases when loaded with H_2. EGON BRETSCHER

The dependence of the counter-potential on the strength of the field and the true conductivity of ion crystals. O. BERAN AND F. QUITTNER. *Z. Physik* **64**, 760–76 (1930).—The counter potential of NaCl and KCl is measured between 100° and 200° in a field up to 28,000 v. immediately (10^{-3} to 10^{-6} seconds) after breaking the connection to the charging potential. In contradistinction to Joffé's assumption (cf. *Z. Physik* **48**, 288(1928)) the true cond. increases with the field. The temp. variation of the const. and the true cond. obey van't Hoff's formula. A zero compensation method is used to measure the counter-potential and a Helmholtz pendulum to release the contacts. EGON BRETSCHER

The theory of supraconductivity of elements. II. The fundamental idea of the origin of supraconductivity. Z. A. EPSTEIN. *Z. Physik* **63**, 640–59(1930); cf. *C. A.* **24**, 5197.—Between atoms in supraconductors local regions are assumed within which adjoining atoms exert no influence so that electrons moving therein are not deflected. If D is the force directing the oscillation of an atom in the metal lattice and v is the at. vol., $D\beta v^{2/3}$ should be const. and is found to be so for all supraconductors. The theory provides explanations for such characteristic properties as threshold value of current and field, temp. variation of the threshold value and the influences of elastic deformation and of impurities. EGON BRETSCHER

Variation in resistance of a nickel wire that is heated while under tension. S. ARZIBUISHEV AND V. J. U. YUSHAKOV. *Z. Physik* **64**, 405–10(1930).—The resistance of a Ni wire that is heated while under tension decreases at first, reaches a min., and then increases again. This phenomenon disappears at the Curie point, showing that it is connected closely with ferromagnetism. EGON BRETSCHER

A new method for determining transport numbers of solid substances. W. JOST AND H. SCHWEITZER. *Z. physik. Chem.*, Abt. B, **10**, 159–60(1930).—The calcns. were made (details not given) from the lineal expansion under influence of the current, with correction for thermal expansion, for cylinders of NaCl. At 560° $n_{Na} = 0.85$; at 600°, 0.45; and at 650°, 0.35. GREGG M. EVANS

Thermodynamic study of surface tension, affinity and rate of adsorption. VI. RAYMOND DEFAY. *Bull. sci. acad. roy. Belg.* [5], **16**, 598–605(1930); cf. *C. A.* **24**, 5589.—Math. In a system in equil. any arbitrary portion constitutes a sep. equil. The equil. conditions and the surface tension equations of Gibbs are obtained. *Ibid* 741–54.—Math. The formula of Kelvin which relates the vapor tension of a liquid to the radius of curvature of the surface is generalized for the partial pressure of a multicomponent system in terms of fugacity. The topics treated include influence of liquid surface curvature on the condensation pressure of a vapor mixt., on the partial pressure of inert gas mixts., liquid mixts. and two-phase liquids. G. M. MURPHY

Sexl's theory of adsorption. A. GANGULI. *Z. Physik* **64**, 81–3(1930).—Sexl's adsorption formula (cf. *C. A.* **22**, 866) is identical with that of Kar-Ganguli (*C. A.* **24**, 2656). EGON BRETSCHER

Determination of the adsorbed gaseous film on a metallic surface by means of a balance. J. STROHHÄCKER. *Z. Physik* **64**, 248–61(1930).—Air is adsorbed on gold in a unimol. layer as shown by direct weighing. The balance had a sensitivity of 2.6 10^{-6} g. The metal loses the adsorbed gases in a vacuum of 10^{-5} mm. in the course of 30 hrs. EGON BRETSCHER

The sorption of carbon tetrachloride at low pressures by activated charcoal. II. Isothermals at 25°. A. J. ALLMAND AND R. CHAPLIN. *Proc. Roy. Soc.* (London) **A129**, 235–51(1930). **III. Isoteres.** Discussion. *Ibid* 252–66; cf. *C. A.* **23**, 1331.—The isothermal sorption of CCl_4 vapor on 6 different activated charcoals, at pressures from 0.1 to 0.001 mm. of Hg, was investigated. The charcoals were degassed at 110° or 800°. The isotherms were not reversible. Strong hysteresis occurred unless a large amt. of vapor was sorbed before the desorption and resorption measurements. The sorbed vapor slowly displaces CO_2 and permanent gases (largely CO) from the C surface. Reversibility of the isotherms was approached rather closely if this procedure was followed, and allowance made for the partial pressures of the displaced gases. Degassing at 800° was not effective for removing all residual gas, although CO_2 was completely eliminated. Steam-activated charcoals are the best sorbents for CCl_4 vapor at low pressures. Sorption isoteres were obtained from 0° to 90°. The mol. heat of sorption, calcd. from the slope of the isoteres, decreases with increasing amt. of vapor sorbed until a value of 14.6 cal. is reached. It remains const. at this value over a range of 10–20 mg. sorbed per g. of sorbent (depending on the charcoal used). This step is followed

by further increase in the heat of sorption with amt. sorbed. Charcoal evacuated at 800° gives a smooth curve without the step. The adsorption potential of the C surface appears to vary from point to point. The high-potential centers especially are initially poisoned by residual O, which is gradually displaced as CO_2 and CO by the action of the sorbate. C. W. WILSON

Theory of Brownian motion. G. E. UHLENBECK AND L. S. ORNSTEIN. *Phys. Rev.* **36**, 823–41(1930). BERNARD LEWIS

Benzene dispersions of basic soaps of nickel and iron. B. C. SOYENKOFF. *J. Phys. Chem.*, **34**, 2819–38(1930).—*Ni* and Fe^{+++} *stearates*, prepd. from the chlorides and Na stearate in aq. soln., contain basic soaps and uncombined acid. The Ni soaps thus obtained are insol. in C_6H_6 (I) if the free stearic acid (II) is removed. Ni stearate prepns. of more uniform compn. and behavior result from Ni acetate and II at 100° *in vacuo*. Low diffusibility (corresponding to mol. wt. of 18,000 or more), Tyndall cone, gel formation, etc., show that the basic Ni soaps form colloid dispersions in I which are stabilized by II. Fe stearate prepns., on the other hand, are more sol. in I, do not require the addn. of II for stability and form more highly dispersed systems (mol. wt. from ebullioscopic measurements about 2500). The d.-compn. curves of both the Ni and Fe soaps in I are rectilinear. The sp. cond. of II in I is too low to account for the peptizing action of II on basic Ni stearate on the basis of ionic adsorption; therefore peptization and colloid stability are possible in the absence of ions. The lower fatty acids (lauric, caproic) have a greater stabilizing effect than II. B. SOYENKOFF

Micellar equilibria and equilibria of Donnan. J. DUCLAUX AND R. TITÉICA. *Rev. gén. colloïdes* **8**, 251–9(1930); cf. *C. A.* **24**, 10.—The Donnan theory of the equil. of membranes is tested by a series of expts. A study of the hydrosols of $Fe(OH)_3$, $Th(OH)_4$, $FeCl_3$, $K_4(CuFe(CN)_6)_2$, Congo red and caramel showed that the compn. of the ultra-filtrate is independent of the pressure of filtration, the concn. of the micelles, the nature of the ultra-filtration membrane and of the e. m. f. of filtration. A heterogeneous equil. is attained. C. W. SONDERN

The constitution of soluble protein substances as reversible, dissociable component systems. S. P. L. SØRENSEN. *Kolloid-Z.* **53**, 102–24(1930).—The exptl. and theoretical work on other substances of high mol. wt. are compared. The exptl. work on sol. proteins is reviewed and explained by considering a protein as a mixt. of components which are held together by secondary valences, a view similar to Meyer and Mark's theory of the constitution of cellulose. Also in *Compt. rend. trav. lab. Carlsberg* **18**, 1–124(1930). ARTHUR FLEISCHER

The depolymerization of inulin. HANS H. SCHLUBACH AND HORST ELSNER. *Ber.* **63B**, 2302–4(1930); cf. *C. A.* **24**, 2729.—Reply to E. Berner (*C. A.* **24**, 5730). B. concluded that the degradation of inulin (I) as carried out by many workers and observed by cryoscopic measurements is not real but only apparent and is due to the adsorption of solvents with which the compd. has been treated so that the mol.-wt. detns. give too low a value. It is pointed out that the difructose anhydride isolated from squills differs from I but is identical with the degradation product obtained by Vogel and Pictet by heating I in glycerol. The relative ease with which I hydrolyzes throws doubt upon its stability at 120°. Moreover, a sample heated in glycerol, 7 times pptd. from alc.-ether and dried for 12 hrs. at 111° at 0.001 mm., gave no qual. test for either alc. or glycerol. Further evidences that degradation actually occurs are: the change in such phys. consts. as sp. rotation caused by heating I in glycerol and the possibility of sepg. the product into fractions. R. C. HOCKETT

Dissociation of calcium citrate. WALDO J. WILEY. *Biochem. J.* **24**, 856–9(1930).—Cond. measurements agree well with titration of citric acid and $Ca(OH)_2$. The degree of dissocn. at different dilns. is calcd. BENJAMIN HARROW

Mobility of an iron-containing ion. II. Influence of substitution in the outer sphere upon complex iron ions. FRANZ HÖLZL. *Monatsh.* **56**, 79–96(1930); cf. *C. A.* **24**, 2939.—The influence of substitution in complex iron cyanide ions, etc., upon the mobility of the complex ion was studied. GREGG M. EVANS

The relation between ionic charge and size. G. v. HEVESY. *Z. physik. Chem.*, Abt. A, **149**, 472–4(1930).—Diffusion const. of uni-, bi- and tervalent ions obtained from the data of Kohlrausch, Heydweiler and Lorenz agree fairly well with diffusion consts. calcd. according to *Nernst's method*. The H and OH ions were not considered. FRANK URBAN

Further investigations on the kinetics of gaseous oxidation reactions. R. FORT AND C. N. HINSHELWOOD. *Proc. Roy. Soc.* (London) **A129**, 284–99(1930); cf. *C. A.* **24**, 3699.—The rates of oxidation of CH_4, MeOH and HCHO were studied by the static method, at various temps. and partial pressures of reactants. In all cases an initial

induction period was observed. During this period the concn. of intermediate products increased until they were oxidized as fast as they were formed. The reaction products are mostly CO and steam, with very little CO_2. The concn. of combustible gas influenced the reaction rate greatly, but the concn. of O had little effect. The rate increased with greater concn. of combustible gas. The heats of activation of the oxidation of CH_4, MeOH and HCHO are 61,500, 62,500 and 20,600 cal., resp. A chain mechanism is postulated, in which the chains end only at the walls of the vessel. Increasing the surface of the vessel decreased the reaction rate. This is a contrast to the behavior of C_6H_6, in which it was found that the chains ended principally in the gas unless the vessel was very small. An adsorbed layer of O on the walls probably plays an important part in breaking the chains. A theory based on these assumptions agrees in general with exptl. results. C. W. WILSON

Contribution to the thermodynamics and kinetics of heterogeneous equilibria. CH. SLONIM. *Z. Elektrochem.* 36, 439–53(1930); cf. *C. A.* 23, 4631.—Large differences between exptl values for the formation of hydrates from their oxides plus water and values calcd. from pressure measurements of thermal decompn. indicate more complicated changes in nature than are usually assumed. Lines of Röntgen spectra of analcite, chabasite, natrolite, harmotome and stilbite were examd. and found to be similar for the first dehydrated form. The lines changed, however, on further heating. The decompn. of $CaCO_3$ was studied. The differences are accounted for by a "pseudo structure form," which results from the first change during thermal decompn. L. P. HALL

The lead–silver system. F. YOLDI. *Anales soc. españ. fís. quím.* 28, 1055–65 (1930).—Thermal relations of the Pb–Ag system contg. 1.50–10% Ag, previously neglected, were studied, and primary and eutectic crystn. found. This double crystn. is lacking only in the 2.19–2.51% region, thus fixing as eutectic the compn. Pb 97.70–Ag 2.30%. A complete photomicrographic study is shown. Conclusion: Miscibility is complete in a liquid state. E. M. SYMMES

An introduction to chemical catalysis in homogeneous systems. ROBERT LIVINGSTON. *J. Chem. Education* 7, 2887–2903(1930). E. H.

Heterogeneous catalysis and chemical sorption. ERWIN SAUTER. *Z. Elektrochem.* 36, 874–81(1930)—A general theoretical review of the subject. S. LENHER

Studies of the catalytic action of subdivided metals. V. Adsorption isotherms and the state of the adsorbed hydrogen. B. FORESTI. *Gazz. chim. ital.* 60, 516–9 (1930); cf. *C. A.* 23, 4615.—From exptl. data of Kistiakowsky, Flosdorf and Taylor (*C. A.* 21, 3535) relations are deduced between the vols. of H adsorbed by active Cu and by annealed Cu and the pressures (from 0.03 to 0.3 mm of Hg). These relations are of the type $L = K\sqrt{p-m}$. If m is neglected, the relations become quadratic, in which case the most active centers would be satd. by H atoms, in the case of both active Cu and annealed Cu. This is in contrast to measurements of the differential heats of adsorption which have already been carried out on the same samples. On the other hand it is possible to foresee quadratic relations on the basis of a mol. adsorption, even at low pressures. C. C. DAVIS

The heat of formation of molecular oxygen. L. COVELL COPELAND. *Phys. Rev.* 36, 1221–31(1930); cf. *C. A.* 24, 3702.—An app. is described for producing at. O_2 and directly detg. the heat of formation of mol. O_2. The expts. were conducted in the pressure range 0.1 to 0.55 mm. Hg. The heat of formation is given as 131,000 ± 6000 cal. per g. mol. wt. Several of the properties of at. O_2 were investigated, including the possibility of long-lived metastable states. BERNARD LEWIS

The heat transfer coefficient for aqueous solutions of sodium chloride, calcium chloride, magnesium chloride, and "Reinhartin" at turbulent flow in tubes. K. LINGE. *Z. ges. Kälte-Ind.* 37, 194–6(1930).—The heat transfer coeff., α, $= 1750(1 + 0.017t)\cdot[1 - c(\gamma - 1)]\frac{w^{0.87}}{d^{0.13}}$, where w is the velocity in m./sec.; d is the tube diam. in m.; t is temp.; γ is the sp. gr. in kg./cu. m.; α is in $\frac{\text{kg.-cal.}}{\text{sq. m. per degree per hr}}$. The values of c for these solns., at temps. of −30° to +10°, are given as: H_2O, 1; NaCl (to −21°), 1.2; $CaCl_2$, 1.5; $MgCl_2$, 2.4; "Reinhartin," 1.8. F. D. ROSSINI

Remark on the thermal dissociation of nitrous oxide. C. N. HINSHELWOOD *Z. physik. Chem.*, Abt. B, 10, 157–8(1930).—Polemical with Volmer and Kummerow (cf. *C. A.* 24, 4980). GREGG M. EVANS

An improved Victor-Meyer molecular-weight apparatus (HICKS-BRUUN) 1. A micro furnace for temperatures above 1000° (ROBERTS, MOREY) 1. Polarization of the Raman radiation and crystal structure (MATOSSI) 3.

Application of integral equations to diffraction and the proper frequencies in the electromagnetic theory of light. W. STERNBERG. *Z. Physik* **64**, 638–49(1930). E. BRETSCHER

Equations of motion of the electron. USAKU KAKINUMA. *Proc. Phys.-Math. Soc. Japan* [3], **12**, 159–66(1930).—Math. MALCOLM DOLE

The matrix mechanics of the spinning electron. G. TEMPLE. *Proc. Cambridge Phil. Soc.* **26**, 496–506(1930). E. H.

Thread-shaped, visible electron rays. E. BRÜCHE AND W. ENDE. *Z. Physik* **64**, 186–90(1930).—It is possible to obtain non-divergent visible electron rays of 100–200 v., $^1/_4$ sq. mm. cross section and 1 m. length from a glowing cathode with suitably chosen emission and gas pressure. The high usefulness of these rays, especially for the study of magnetic fields, is pointed out. EGON BRETSCHER

Diamagnetism in metals. L. LANDAU. *Z. Physik* **64**, 629–37(1930).—Free electrons possess, according to the quantum theory, a diamagnetism which is $^1/_2$ of the paramagnetism due to the spin. The possible influence of this effect on electrons in a metal or paramagnetic insulator is discussed. EGON BRETSCHER

A representation of the diagram of the elements according to Corbino. A. MAZZUCCHELLI. *Gazz. chim. ital.* **60**, 531–4(1930).—The diagram of Corbino (cf. *Nuovo cimento* **61**(1923)), in which the elements are arranged according to the quantum nos. of the electrons, can be developed further by utilizing the subsidiary quantum no. l as well as the principal quantum no. n. When the diagram is turned 90° (mutual change of abscissa and ordinate) so that the heterologic elements are arranged in horizontal lines instead of vertically, an arrangement resembling the ordinary Mendelyeev table is obtained. This gives a system which shows the genetic dependence of the periodic system on the quantistic distribution of the electrons around at. nuclei. The newly arranged table of elements is shown, and is discussed in detail. C. C. DAVIS

A simple graphic method for the evaluation of Debye-Scherrer diagrams. WERNER EULITZ. *Z. Physik* **64**, 452–7(1930).—The lattice const. may easily be obtained without any calcn. from the scattering angles by means of a nomographic diagram. The advantages of the method are restricted to crystals of the cubic system. E. B.

A method of obtaining the Hull-Debye-Scherrer pattern of cathode rays. KYUZI MATUKAWA AND KEN'ICHI SHINOHARA. *Proc. Phys.-Math. Soc. Japan* [3], **12**, 171–5 (1930).—Pt, Au and Ag sputtered on glass plates were investigated with cathode rays. Fine diffraction rings were obtained and tables of their values are given. M. D.

The ionization of gases by x-rays of short wave length. KLAUS SCHOCKEN. *Z. Physik* **64**, 458–64(1930).—Monochromatic x-rays (reflected from calcspar) are allowed to fall into an ionization chamber contg. O_2, A or MeCl. The ionization current for the different gases is measured as function of the pressure. The total ionization current I is partly due to the photoelectrons ($I_p = N^3\rho\ a$, N effective at. no., ρ density of the gas) and partly to recoil electrons ($I_r = b\rho$). From 2 observations the relative contribution of photoelectrons as function of the wave length (between 0.139 and 0.421 A. U.) is obtained. For $\lambda > 0.35$ A. U. I_r becomes negligible. EGON BRETSCHER

Scattering of x-rays by water and aqueous solutions. WILLIAM GOOD. *Helv. Phys. Acta* **3**, 205–48(1930).—A thin film of water or an aq. soln. of a salt (LiCl, $CaCl_2$, $(NH_4)_2SO_4$, K_2CO_3, KCl, KBr, KI, $BaCl_2$) is irradiated with Cuα radiation. By taking account of the absorption as function of the angle of scattering, 2 diffraction rings are obtained for water, one resulting from intramol. interference; the other is attributed to small ice crystals (assocd. water mols.) suspended in the liquid. The scattered intensity is given diagrammatically for every salt soln. EGON BRETSCHER

Passage of the electric current through solid paraffin in the dark and while irradiated by Röntgen rays. V. M. TUCHKEVICH. *Ann. Physik* [5], **6**, 622–36(1930).—Continuing work previously reported from the same lab. (cf. Nasledov and Sharavskii, *C. A.* **24**, 779, 5551) and using similar app., T. has measured the cond. of solid paraffin in layers 1.3, 5, 10, and 20 cm. in thickness between Al electrodes 5.5 cm. long and 0.5 mm. in thickness in the dark and while being irradiated by x-rays from a W anticathode at 25°. The current was detd. by measuring the time required to charge an electrometer to a certain potential. In the dark the magnitude of the current decreased very rapidly at first and then almost imperceptibly, giving indication that a residual current was present. The principle of similarity of B. and I. Kurchatov (*J. Russ. Phys.-Chem. Soc. Phys.* **61**, 332(1930)) was confirmed in paraffin within the limits of exptl. error, which were not small. The irradiated paraffin, like the ceresin of previous workers, showed a much greater conductance than the same substance in the dark. The time necessary to reach a max. after beginning of irradiation is dependent upon the thickness of the layer but is independent of the time elapsing between turning on current and irradiating the sample. During irradiation the current passing is proportional to all the potential gradients measured (max. 12,000 v./cm.) *i. e.*, Ohm's law is valid. The principle of similarity also holds. A diagram of the app. and data in the form of curves are given. E. R. SCHIERZ

Intensity of total scattering of x-rays by monatomic gases. Y. H. WOO. *Nature* **126**, 501–2(1930).—Raman's (*C. A.* **23**, 3853) and Compton's (*C. A.* **24**, 3425) method of calcn. is changed so that the calcn. of the intensity of the total scattering depends on the evaluation of the radial charge distribution of the electrons in the atom. This involves the assumption of $4\pi r^2 Zp(r)dr$ as the probable no. of electrons between r and dr. ARTHUR FLEISCHER

Extension and intensity of Debye lines or rings as function of the dimensions of the tube focus, the camera and the preparation. W. BUSSE. *Z. Physik* **63**, 227–44 (1930).—The calcn. is limited to a small or very high absorption coeff. of the sample The intensity of a Debye line is obtained as function of the breadth and length of the focus of the tube and the distance from the center of the line. A max. abs. intensity results, if the breadth of the focus is such that the natural breadth of the line is doubled. EGON BRETSCHER

β-Radiation and energy principle. J. KUDAR. *Z. Physik* **64**, 402–4(1930).—To explain the existence of the continuous β-ray spectrum and the well-defined decay const., it is assumed that the β-particle possesses a sharp energy inside the nucleus equal to the mean energy of the β-ray spectrum. The law of the conservation of energy is supposed to hold only statistically. EGON BRETSCHER

The discrete range groups of H particles from aluminum. I. Dependence of the yield and the energy of the H particles on the primary energy. H. POSE. *Z. Physik* **64**, 1–21(1930).—An Al-foil is bombarded with α particles whose energy is varied by interposing a screen between the radioactive prepn. and the Al. The H rays leaving the Al in the same direction are detected in an ionization chamber. Of the 3 groups of H rays previously reported (*C. A.* **24**, 5219), 2 are only observed if the energy of the α rays is of a characteristic narrow limited magnitude. Faster and slower α particles do not give rise to the ejection of an H particle. The last group of H particles is produced irrespective of the primary energy of the α rays. EGON BRETSCHER

The theory of atom disintegration. GUIDO BECK. *Z. Physik* **64**, 22–33(1930). The theoretical explanation of the exptl. results of Pose (cf. preceding abstr.) is given. For a certain characteristic energy of the α particle, a resonance effect occurs inside Gamov's potential trough, which leads to a transition of an α particle to a lower energy level and to the emission of an H particle of definite velocity. There are also possible transitions of α particles to levels of the continuous spectrum with transfer of the energy to H particles. No distinct energy is necessary for a process of this type. For both cases the angular distribution of the H particles is calcd. EGON BRETSCHER

The theory of molecular forces in dipole gases. H. MARGENAU. *Z. Physik* **64**, 584–97(1930).—The second virial coeff. is calcd. with quantum mechanics. For high temp. ($kT \gg h^2/8\pi^2 A$, A = moment of inertia) the classical formula results. Approximations for low temp. are obtained and an elegant quantum mech. deduction of the Langevin-Debye formula for the polarization of a dipole gas is given. E. B.

Exchange of electrons by slow ions. II. H. KALLMANN AND B. ROSEN. *Z. Physik* **64**, 806–16(1930); cf. *C. A.* **25**, 26.—To demonstrate charge transfer directly, a secondary ring electrode with neg. potential (—3 v.) surrounds the receiver of a K. and R. mass spectrograph. The beam of original fast ions is not deflected by the weak field due to the ring electrode, but the slow ions resulting from charge transfer

are collected on it. The charge on this electrode measures the degree of charge transfer. Previous results are confirmed. Ions exchange electrons easily with atoms of the same kind (A^+ in A, N_2^+ in N_2), but the exchange is negligible with atoms of different energy of ionization. (A^+ in N_2, N^+ in A.) N^{++} is partly converted to N^+. Details are given to distinguish between the reactions $A_f^{++} + A_s = A_f^+ + A_s^+$ and $A_f^{++} + A_s = A_f + A_s^{++}$. ($s$ and f refer to slow and fast particles.) The interaction of Hg^{++} and Hg^+ with Hg and N_2 is briefly mentioned. EGON BRETSCHER

Energies of the C—I and C—Br bonds. T. IREDALE AND A. G. MILLS. *Nature* 126, 604(1930).—The long wave length limit at 3340 A. U. and maxima at about 2550 A. U. for ultra-violet absorption bands from Me, Et and iso-Am iodides and bromides is taken to mean dissocn. into a halogen atom and an alkyl residue. From these data the energy has been calcd. as 64 cal. for the C—I and 91 cal. for the C—Br bonds. GREGG M. EVANS

The question of the separation of isotopes. K. P. YAKOVLEV. *Z. Physik* 64, 378–91(1930).—A fine beam of pos. rays is sepd. into the isotopes by elec. and magnetic deflection. The ray consisting now of particles of uniform mass enters an evacuated bulb closed with a very fine film of glass. It is calcd. that approx. 0.03 cu. mm. of Ne^{20} and Ne^{22} have under the given exptl. conditions been collected. The spectra differ less than 0.006 A. U. EGON BRETSCHER

The intensities of doublet lines according to Dirac's theory. K. BECHERT. *Ann. Physik* [5], 6, 700–20(1930).—A derivation of expressions for the intensities of doublet lines on the basis of Dirac's theory. The Hönl-Sommerfeld intensity formulas (*C. A.* 19, 1988) are shown to result from these expressions for a Coulomb field and small relativity corrections. For increasing values of the relativity corrections the expressions show deviations from the Hönl-Sommerfeld formulas. C. C. KIESS

Notes on the spectra of ten bright-line stars of classes B and A. PAUL W. MERRILL. *Astrophys. J.* 72, 98–110(1930).—Peculiarities are described in the spectra of 10 stars which exhibit bright H lines. C. C. KIESS

The spectrum of gamma Geminorum (class A). SEBASTIAN ALBRECHT. *Astrophys J.* 72, 65–97(1930).—The wave lengths have been detd. of more than 900 absorption lines in the spectrum of γ Gem. between 4250 and 4723 A. U. These, for the most part, have been identified with lines emitted by the neutral and singly ionized atoms of H, Mg, Fe, Ti, Cr, Mn, V, etc., many of the strong lines being due to the ionized atoms. C. C. KIESS

The Stark effect of aluminum and carbon. YOSHIO ISHIDA AND M. FUKUSHIMA. *Sci. Papers Inst. Phys. Chem. Research* (Japan) 14, 123–43(1930)(in English).—Elec. fields of 300–500 kv./cm. were employed to observe the Stark effect for lines of Al and C. Tables give the results obtained for Al I between 3961 and 2204 A. U.; and for C II between 4267 and 2574 A. U. C. C. KIESS

Terms of the arc and spark spectra of chromium. C. C. KIESS. *Bur. Standards J. Research* 5, 775–9(1930).—Tables of terms of Cr I and Cr II are given which account for nearly all the lines of these spectra likely to prove of phys., chem. or astrophysical importance. The terms of Cr I belong to the septet, quintet and triplet systems; those of Cr II belong to the sextet, quartet and doublet systems. All the terms given conform to those required by theory. C. C. KIESS

Intensity measurements in the copper arc. L. S. ORNSTEIN AND D. VERMEULEN. *Z. Physik* 64, 657–9(1930).—The intensity ratio of the Cu lines: 1^2S-2^2P_1 and 1^2S-2^2P_2 as function of the intensity of current has a max. at 0.9 amp. This inconstancy of the ratio points to pronounced self absorption that has been overlooked by Nottingham (*C. A.* 23, 2356). EGON BRETSCHER

The hyperfine structure of the lithium-II spectrum. P. GÜTTINGER. *Z. Physik* 64, 749–59(1930).—The hyperfine structure of the $2s$-$2p$ line of ortho Li^+ can be explained if the nuclear spin has the value $i = (3/2)\ (h/2\pi)$. EGON BRETSCHER

The Doppler effect in slow hydrogen canal rays. FRANZ NEY-VALERIUS. *Ann. Physik* [5], 6, 721–38(1930).—The app. and method for observing the Doppler effect of slow canal rays in H are described. The potentials applied to the tubes ranged from 400 to 1200 v. The max. velocity of the effect was observed to agree closely with that derived from the cathode potential drop by means of the relation $\frac{1}{2}\ mv^2 = Ve$. Between 400 and 1000 v. 2 velocity max., v_1 and v_2 were observed. It was found that the ratio $v_2:v_1$ decreased with increasing pressure in the tubes. Between 1000 and 1200 v. 4 max. were observed. These are attributed to the existence in the canal rays of the ions H_1^+, H_2^+, H_3^+ and H_4^+. With tubes at higher pressures two velocities corresponding to neg. canal rays were observed. These are attributed to the particles H_1^- and H_2^-, moving in a direction opposite to that of the pos. ions. C. C. KIESS

The Stark effect of the resonance line of mercury and its relation to magnetic fields. PAUL BRAZDZIUNAS. *Ann. Physik* [5], 6, 739–71(1930).—The app. and method used for detg. the min. Stark effects of the Hg line 2536.7 A. U. have been described by Schein (*C. A.* 23, 4888). It was found that an elec. field of 100,000 v./cm. causes a red shift of the perpendicular components of 5.4×10^{-4} A. U., and that a field of 140,000 v./cm. was required to produce a shift of 1.9×10^{-4} A. U. in the parallel component. The displacements were found to be proportional to the square of the field. With a superposed magnetic field parallel to the elec. field there appeared a quenching of the Stark effect after the magnetic field attained a definite magnitude. The same was noted when the magnetic and elec. fields were crossed. C. C. KIESS

The impact broadening of the rotation-oscillation spectra of gases. VLADIMIR LAZAREV. *Z. Physik* 64, 598–605(1930).—The broadening effect of gases (air, A, HCl, HBr) on the absorption lines of HCl and HBr in the infra-red is only due to damping by impact and not to mutual coupling. EGON BRETSCHER

Deformation of electron shells. II. Absorption spectrum, molecular volume and refraction of certain rare earth salts. P. W. SELWOOD. *J. Am. Chem. Soc.* 52, 4308–16(1930); cf. *C. A.* 24, 4986.—The mol. vol. of aq. soln. of $Nd(NO_3)_3$ and $NdCl_3$ increases with concn.; the mol. refraction increases for the nitrate and decreases for the chloride. The absorption spectra shift toward the red, indicating deformation of the Nd ion in concd. soln. For $Pr(NO_3)_3$ and $Sm(NO_3)_3$ the spectrum shifts toward the red; for $Eu(NO_3)_3$ and $GdCl_3$ no shift is noted. Solns. of $Ho(NO_3)_3$ and $Er(NO_3)_3$ displace the spectrum toward the blue with increasing concn. G. M. MURPHY

Residual rays of univalent and bivalent fluorides. O. REINKOBER AND M. BLUTH *Ann. Physik* [5], 6, 785–92(1930).—The residual rays of several fluorides were isolated by the original method of Rubens. The results of the wave-length measurements are 35.8μ for NaF; 48.6μ for TlF; 40.7μ for Sr_2F; and 50.7μ for Ba_2F. These results make the data for the fluorides comparable with those already found for the chlorides and bromides. C. C. KIESS

The behavior of the bands of nuclear oscillation of the ammonium radical in the transition range. LISELOTTE WILBERG. *Z. Physik* 64, 304–24(1930).—The optical transparency of solid NH_4Cl for light from 0.8μ to 16μ at room temp. and at $-50°$ is measured in continuation of the work of Hettner and Simon (cf. *C. A.* 23, 1058). Three types of absorption bands are found at: I. 3.2 and 7μ, whose intensity does not vary with temp. II. 3.5, 4.25, 4.45, 4.90 and 5μ; the intensity increases considerably with decrease in temp. III. 6.8–6.95μ intensity decreases with decreasing temp. The bands at 5.6μ and 6.95μ exhibit at $-30.3°$ a discontinuous change of intensity. Interpretation of the exptl. results: Two states *a* and *b* with different energies are possible I belongs to *a* and *b*, II to *a* and III to *b*. EGON BRETSCHER

Polarization of the Raman radiation and crystal structure. F. MATOSSI. *Z. Physik* 64, 34–8(1930).—The polarization of the Raman radiation for different crystal positions of *calcspar* and $NaNO_3$ is compared. From the theory (classical) of Mandelstam, considerations of symmetry and the exptl. results, it is concluded that the CO_3 groups are equilateral and are always arranged in antiparallel pairs. E. B.

Raman effect and molecular structure. II. B. TRUMPY. *Z. Physik* 64, 777–8(1930); cf. *C. A.* 24, 5229.—The Na salts of fumaric acid (I), maleic acid (II), mesaconic acid (III) and citraconic acid (IV) give in aq. soln. (15%) the following Raman lines (I): 1277, 1407, 1656 cm.$^{-1}$; (II) 1405, 1646 cm.$^{-1}$; (III) 2930, 1652, 1447, 142[illegible] 1398, 1294 cm.$^{-1}$; (IV) 2916, 1653, 1449, 1401, 1267, 1210 cm.$^{-1}$. The intensities of corresponding lines differ for the various salts. EGON BRETSCHER

Raman effect in hydrogen sulfide. S. BHAGAVANTAM. *Nature* 126, 502 (1930).—Liquid H_2S shows an intense sharp line shifted by 2578 wave nos. from the exciting Hg radiation. Gaseous H_2S shows a more diffuse line shifted 2615 wave nos. The liquid H_2S line is at the same position as that observed for the org. hydrosulfides. ARTHUR FLEISCHER

Splitting of the frequency of light scattered by liquids and optical anisotropy of molecules. E. GROSS. *Nature* 126, 603–4(1930).—In scattering of light by liquids the 2 inner components and the unmodified line are polarized, but outer ones are not. Expts. with CS_2, H_2O, Et_2O, EtOH and ArCl show that in strongly depolarizing liquids these outer lines are intensified. This result is attributed to optical anisotropy of the mols. themselves. GREGG M. EVANS

Form of optical absorption bands in solutions. WERNER KUHN AND E. BRAUN *Z. physik. Chem.*, Abt. B, 9, 426(1930); cf. *C. A.* 24, 5630.—Addn. of a literature reference to a previous article. J. B. AUSTIN

The scientific foundations of photochemistry. MAX BODENSTEIN. *Z. angew. Chem.* 43, 819–23(1930).—A brief review. C. E. P. JEFFREYS

Observations by positive-ray methods on the breaking-down and the building-up of hydrocarbons in discharge tubes. O. EISENHUT AND R. CONRAD. *Z. Elektrochem.* 36, 654–62(1930).—Using a perfected pos.-ray app., the authors investigated CH_4, mixts. of $CH_4 + O_2$, mixts. of $CO_2 + H_2$, C_2H_6, C_2H_4 and C_2H_2. With CH_4, the decompn. products (exclusive of H_2) were CH, CH_2 and CH_3; the built-up products were C_2, C_4, C_2H, C_2H_2, C_2H_4 and C_2H_6. (In the preceding and in the following the pos. ionic charge has been omitted.) Mixts. of CH_4 and O_2 gave CH_3, CH_2, CH and C (masses 15–12) and built-up products C_2 to C_2H_6 (24–30); CO (28) was very strong; C_2O (mass 40) was also observed. In contrast to these results are the results with CO_2 and H_2. Here CH, CH_2 and CH_3 are built-up products; very faint lines corresponding to masses 24–27, 29 and 30 were observed; CO and O were also observed. C_2H_6 gives decompn. parabolas for masses 29–24, 15–12 corresponding to C_2H_5 to C_2 and CH_3 to C, resp.; lines above mass 36 are purely built-up products. C_2H_4 is decompd. into 27–24 (C_2H_3 to C_2) and 14–12 (CH_2-C); 29, 30, 36–42 are built-up products. C_2H_2 gives C_2H, C_2, CH and C as decompn. products and C_2H_3, C_2H_4, C_2H_5, C_2H_6, C_3, C_3H, C_4H and even higher, as built-up products. LOUIS WALDBAUER

Photochemical polymerization of acetylene. S. C. LIND AND R. S. LIVINGSTON. *J. Am. Chem. Soc.* 52, 4613–4(1930).—The complete radiation of a quartz Hg arc was used. The reaction vessel was 3 cm. deep. The reaction velocity was proportional to the pressure of C_2H_2 up to 30 cm. pressure; at higher pressures it tended to become const. Comparison of the rate at 12° and 39° gives a value for the 10° temp. coeff. of 1.25, which may be largely the temp. coeff. of the light absorption. Light of wave length 2537 A. U. and longer is not effective. A weighted av. of $M/h\nu$, for 3 detns., is 7.4 ± 2.5, the uncertainty being due to the pptn. of cuprene on the walls of the reaction cell. C. J. WEST

Investigations on the photochemical decomposition of tartaric acid in presence of citric acid. TITO PAVOLINO. *Giorn. farm. chim.* 79, 310–3(1930).—Solns. of α-hydroxy acids in the presence of U salts, when exposed to sunlight, decompose slowly, giving rise to formation of HCO_2H and of the resp. aldehydes or ketones. Under these exptl. conditions tartaric acid yields glyoxal and citric acid yields acetone. Glyoxal was identified by means of the reaction occurring on addn. of $PhNHNH_2$: a yellow ppt. of phenylglyoxal osazone is formed, which soon changes its color to a wine-red, probably because of the oxidative effect of the U salt. When p-$H_2NHNC_6H_4SO_3H$ is used instead of $PhNHNH_2$, the soln. assumes an intense golden-yellow color. Based on these findings a method was elaborated for the *detection of tartaric* acid in a soln. of citric acid. The soln. to be examd., after addn. of a U salt, is exposed for at least 30 min. to sunlight or a light source of similar intensity. A few drops of $PhNHNH_2$ (or a corresponding quantity of a 5% soln. of its acetate) is added. The pos. outcome of the osazone reaction as described above indicates the presence of tartaric acid. The reaction appears to be sp., since it was not given by any of the other aliphatic α-hydroxy acids examd. G. SCHWOCH

Photochemical reaction between sodium nitrite and iodine. A. K. BHATTACHARYA AND N. R. DHAR. *J. Indian Chem. Soc.* 7, 709–15(1930).—The reaction $NaNO_2 + I_2 + H_2O = 2HI + NaNO_3$ is found to be bimol. in the dark, and the temp. coeff. is 2.7 between 30° and 40°. The temp. coeffs. of the light reaction vary from 2.07 for λ = 4725 A. U. to 2.35 for λ = 8500 A. U. The quantum efficiency varies from 36 to 119 at different temps. and wave lengths. C. E. P. JEFFREYS

Chemical reactions promoted by light. L. VECCHIOTTI AND G. ZANETTI. *Gazz. chim. ital.* 60, 479–86(1930).—A preliminary note. To obtain information on the action of $PhNO_2$ (I) on org. compds. under the influence of light, a field already investigated by Ciamician and Silber (*Gazz. chim. ital.* 33, 354(1903); 36, 174, 176, 190, 197 (1906)), (1) I and $C_{10}H_8$ (II), (2) I and PhMe (III) and (3) I and cinnamic acid (IV) were exposed in an atm. of N to radiation for 6 months (May–Nov.) and the reaction products analyzed. With I (100 g.) and II (20 g.) the only reaction was that of Lustgarten (*Monatshefte* 3, 720), a trace of β-naphthol being the only product identified. With I (100 g.) and III, BzOH (20 g.) and p-$HOC_6H_4NH_2$ (V) were obtained, showing that the side chain of III is oxidized, while I forms V according to the reaction of Ciamician and Silber (*loc. cit.*). I and IV react differently, several products being obtained, including BzOH, CO_2, PhNHBz (VI), PhN(:O):NPh (VII) and o-HOC_6H_4N:NPh (VIII). The reaction with I and IV is explained by rupture of the double bond of IV with formation of BzH and $OHCCO_2H$, which then oxidize to BzOH and $(CO_2H)_2$, resp. By further oxidation IV passes to CO_2. $PhNO_2$ is reduced to PhNO. The formation of

VI, VII and VIII is explained by reference to the explanation of Ciamician and Silber (*Rend. accad. Lincei* [5] **14**, 265(1905)) for the action of $PhNO_2$ on BzH. Thus VI by decompn. of IV to BzH and oxidation of the latter: $PhNO_2 + BzH \longrightarrow VI + 2BzOH$, or in the following way: $PhNO + 2BzH \longrightarrow VI + BzOH$. VII may be formed thus: $2PhNO + BzH \longrightarrow VII + BzOH$, or by analogy with the reaction of PhNO and PhHNOH (cf. *Ber.* **35**, 1606(1902)) thus: $PhNO + Ph(HO)NBz$ (IX) $\longrightarrow$ VII + BzOH. VIII may be formed from VII by transposition (cf. H. M. Knipscheer, *Rec. trav. chim.* **22**, 1–30(1903)) or thus: PhNO + IX $\longrightarrow$ VIII + BzOH. When the expts. were repeated in darkness, there was no reaction with II and III, while IV forms BzOH and VII. C. C. DAVIS

Photochemical formation of chlorine dioxide from chlorine monoxide in carbon tetrachloride solution. ROSCOE G. DICKINSON AND CECIL E. P. JEFFREYS. *J. Am. Chem. Soc.* **52**, 4288–97(1930).—It was found that the decompn. of Cl_2O by the wave length 4358 A. U. in CCl_4 soln. was accompanied by the formation of considerable ClO_2. In solns. 0.014 to 0.054 *M* in Cl_2O, the initial rate of formation of ClO_2 was found to be about 0.35 mol. per quantum absorbed. The initial rate of decompn. was found to be at least 1.8 mols. of Cl_2O per quantum absorbed. C. E. P. JEFFREYS

Photochemical reduction of tungstic and molybdic acids. S. GHOSH AND A. K. BHATTACHARYA. *J. Indian Chem. Soc.* **7**, 717–21(1930).—The photochem. reduction of molybdic and tungstic acid sols by EtOH was found to follow the zero-mol. law. The velocity consts. were found to decrease when the sol was allowed to age, but increased to a value greater than that for a fresh sol when the sol was heated to 70° for 8 min. The sols become less active photochemically in the presence of univalent ions. The order in which the cations affect the velocity consts. is given as Rb > K > Na > Li. C. E. P. JEFFREYS

Chemical reactions in infra-red radiations. II. A. K. BHATTACHARYA AND N. R. DHAR. *J. Indian Chem. Soc.* **7**, No. 8, 677–85(1930); cf. *C. A.* **23**, 5414.—Sixteen reactions including the reaction of $N_2H_4.HCl$ and I_2; NH_2OH and I_2, and decompn. of Na cobalitinitrite were found to be accelerated by radiations of wave length 8500 A. U. Four reactions including the first 2 mentioned were studied in radiation of mean wave-length 7304 A. U. The quantum efficiencies of all the reactions increase with increase in temp., the temp. coeff. being less than those for the corresponding dark reactions. It was shown photographically that a 1-cm. layer of $K_2Cr_2O_7$ soln. (satd.) in a Co-glass cell cuts off all radiation shorter than 8000 A. U. The authors believe that these expts. show that radiation plays an important part in chem. reactions, and strengthen the radiation hypothesis of chem. change. C. E. P. J.

The photochemistry of alkali and silver halide crystals. R. HILSCH AND R. W. POHL. *Z. Physik* **64**, 606–22(1930).—The absorption spectra of alkali halide crystals show below 250 mμ discrete states of energy which become perfectly clear at —183°. AgCl possesses a broad band spectrum without fine structure, which is not altered by temp. The absorption spectrum of the centers of color in an alkali halide crystal is clearly different from the absorption spectrum of pure crystal. For *AgCl* and *AgBr* both types of spectrum overlap. From the absorption const. for the max. of absorption and the wave length, the no. of color centers is calcd. on the basis of dispersion theory and it is shown that both the latent image of a photographic plate and the coloring of irradiated alkali halide crystals are due to a concn. of one color center to 10^{-6}–10^{-7} salt mols. Furthermore it is shown that the quantum yield amounts to 0.33–0.4 color centers per photon. The reverse process occurs simultaneously with the production of color centers and is also independent of the wave length in the alkali halide crystals; but for AgCl only that part of the absorption curve is lowered which corresponds to the wave length of the incident light. With alkali halides the color centers consist of alkali atoms. *Tl salts* behave practically in the same way as Ag salts. E. B.

The influence of temperature on the absorption spectra of alkali halides. H. FESEFELDT. *Z. Physik* **64**, 623–8(1930).—The absorption max. of *RbBr* (186 mμ) and of *KI* (211 mμ) vary linearly with temp. This frequency shift cannot completely be accounted for by thermal expansion as the observed value is about 4 times larger than that calcd. Details of the measurement of the absorption coeff of a very thin layer of alkali halide (deposited on quartz in a high vacuum) in the ultraviolet between 180 and 280 mμ are given. EGON BRETSCHER

Some more absorption spectra of chemically simple halide crystals. HANS FESEFELDT. *Z. Physik* **64**, 741–8(1930); cf. preceding abstr.—$PbCl_2$, $PbBr_2$, PbI_2, TlCl, TlBr, TlI, AgCl, $CdCl_2$, $CdBr_2$, CdI_2, $ZnCl_2$, $BaBr_2$, $NiCl_2$, $NiBr_2$, NiI_2, $CoCl_2$, $CoBr_2$, CoI_2, InCl possess band spectra (diagrammatically given for each salt) which cannot be resolved even at —183°. EGON BRETSCHER

Condensation of hydrocarbons by electrical discharge. Comparison with condensation by α-rays. S. C. LIND AND GEORGE GLOCKLER. *J. Am. Chem. Soc.* **52**, 4450–61(1930).—The condensations of CH_4, C_2H_6, C_3H_8, C_4H_{10} and C_2H_4 have been studied in the elec. discharge. It is found that these reactions are quite similar to the condensations caused by α-rays. The following factors give evidence of this similarity of reaction: (1) pressure changes as function of time; (2) free H produced during the reaction; (3) relative amt. of H and CH_4 in the H-CH_4 fraction of the resultant gases; (4) the % of liquid conversion; (5) the av. compn. of liquid condensate; (6) the % of the hydrocarbons reacted. All of these factors are quite similar for both types of condensations and it is argued that both types of reaction must be caused by the same mechanism. A reaction scheme is discussed on the basis of the ion cluster theory. The usual ideas are amplified in one respect in that it is assumed that the larger mols. are ionized not only by electron impact but also by electron exchange. C. J. WEST

The Ra in aquatic organisms (VERNADSKII) **11D.** Breaking up natural petroleum emulsions or other colloid systems by use of rays of short wave length (U. S. pat. 1,783,471) **3.**

Radioactive preparations. ALOIS FISCHER. Ger. 506,377, Sept. 1, 1927. See Brit. 278,347 (*C. A.* **22**, 2514) and 285,467 (*C. A.* **22**, 4726).

Lamp emitting ultra-violet radiation. MILAN W. GARRETT (to Westinghouse Lamp Co.). U. S. 1,783,643, Dec. 2. Electrodes which may be formed of W or Mo and between which a discharge may be passed are placed in an envelope such as quartz or special glass contg. A or other suitable monatomic gas with an admixt. of N.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electrical apparatus for the coreless induction furnace. N. R. STANSEL. *Iron Steel Eng.* **7**, 519–24(1930).—An induction furnace is a transformer. The general course is a primary circuit supplied with power at const. voltage and const. frequency and a short-circuited secondary circuit formed by a charge of metal in refractory crucible. The output of this transformer is heat developed by currents induced in the secondary circuit. The magnetic flux of a coreless induction furnace is small and the charge in that flux is rapid. The frequencies used for coreless induction furnaces, in size 50 kw. and above, in metal-melting service range from 480 cycles to 2000 cycles. A frequency of 960 cycles has been adopted as standard for steel-melting furnaces in sizes up to 1000 kw. The corresponding voltages in use range from 440 to 1800 v. The standard for the 960-cycle steel-melting furnace is 800 v. The power factor of a coreless induction furnace is low, 5–15%. At the frequencies used the capacitor is more efficient, less costly, with lower operating and maintenance costs than synchronous condensers. The capacitor is designed primarily for a given micro-farad for operation at a given voltage. The voltage rating dets. the thickness of the dielectric between the electrodes. Factors influencing their design are pointed out. W. H. BOYNTON

The development of the electric resistance furnace. W. J. MILLAR. *Metal Ind.* (London), **37**, 459–62(1930). E. H.

Analysis of electric heat treating of high-grade axes. WIRT S. SCOTT. *Elec. J.* **27**, 511–14(1930).—This is an analysis of the hardening and tempering of axes at the Warren Axe & Tool Co. and shows the comparison in operating conditions between gas-fired and electrically heated furnaces. The summarized monthly costs of heat treating indicate a net profit of $524.10 per month when elec. heat is used. A. D. S.

A small laboratory electric furnace. EUGENE F. COLEMAN. *J. Chem. Education* **7**, 2720–1(1930).—Directions are given for making the app. from a flower pot and a *conical* heating element from a household elec. heater. It may be run at about 1300° for as much as 1 hr. without injury. J. H. MOORE

Manganese in electrolytic zinc practice. OLIVER C. RALSTON. *Eng. Mining J.* **130**, 375–8(1930).—An analysis of available data and a crit. study of the available evidence that formed a considerable part of the testimony in the case of Electrolytic Zinc Process *vs.* French's Complex Ore Reduction, hinging on the validity of a Canadian patent. *Ibid* 510–2.—Points of the testimony in the suit are given. W. H. B.

Applications of the photoelectric cell to chemical analysis and control. H. M.

PARTRIDGE. *Ind. Eng. Chem., Anal. Ed.* 2, 207–13(1930).—A bibliography on photoelec. cells and their uses is included. See *C. A.* 24, 4991. D. K. ALPERN

Electrolytic preparation of arsine and stibine. M. HLASKO AND M. MASLOWSKI. *Roczniki Chem.* 10, 240–7(247 French)(1930).—The best conditions were detd. for the production of AsH_3 and SbH_3 by electrolysis of aq. concd. solns. of AcONa (acidified with AcOH) with an As or Sb cathode, resp. The output of either increased rapidly with increase in current, the p. d. between the electrodes remaining const. Increasing the voltage applied to the cell but keeping the current the same diminished the yield of AsH_3 or SbH_3. The best yield of SbH_3 was obtained with a cathode c. d. of 14 amp./sq. dm. Conclusion: The electrolytic method for the prepn. of AsH_3 and SbH_3 is not practical. J. KUČERA

An electroösmotic theory of the electrolytic rectifier. A. A. DOBIAŠ, L. I. KRAMP AND O. P. LEBEDINSKAYA. *Z. Physik* 61, 852–72(1930); *Bull. acad. sci. union rep. soviet. social. Classe sci. phys. math.* 1930, No. 3, 235–55(in German).—This is a repetition and extension of work previously published by D. (*Memoires Inst. Agron. Empereur Pierre I à Voronège* III(1908)).—According to the authors the electrode during the formative period becomes covered with a porous insulating membrane. The formation of this membrane continues until the electroösmotic pressure can overcome the electrostatic attraction between the electrolyte and the electrode. The mechanism of the valve or rectifying action is probably the following: during the active phase the electrolyte is in contact with the electrode and a current passes; during the inactive phase the electrolyte moves through the membrane away from the electrode causing a great decrease in cond. Because of the fact that Ta electrodes did not show this effect, probably because of the acidic nature of the membrane, the authors refrain from saying that their explanation, important though it is, is the only one which will be able to explain the phenomenon. Exptl. data obtained by the use of Al electrodes in 0.1 *M* solns. of $NaHCO_3$, KOH, LiOH, $AlCl_3$, HCl and HNO_3 are given. E. R. SCHIERZ

Investigation of the electric conductivity of sodium chloride crystals. BORIS HOCHBERG AND ANTON WALTHER. *Z. Physik* 64, 392–401(1930).—The temp. variation of elec. cond. σ from 25° to 250° can be represented by the expression $\sigma = A^{(-B/T)}$; the current is due to the migration of the Na ions. Between 550° and 800° a second term is necessary to take account of the contribution of the Cl ions to cond. A special switch has been constructed to measure the current immediately (10^{-3} sec.) after the potential has been applied to the crystal to avoid the interference of polarization effects. EGON BRETSCHER

Electric discharges in crystals. LYDIA D. INGE AND ALEXANDER F. WALTHER. *Z. Physik* 64, 830–44(1930).—A sudden discharge is allowed to pass through a crystal plate placed between a flat and a pointed electrode. The path of the discharge is studied as function of the symmetry and temp. of the crystal and the sign of the potential and illustrated by a great no. of photographs. The crystals investigated are *rock salt, sylvite, fluorspar, calcite, aragonite, beryl, barite.* EGON BRETSCHER

Dissociation of carbon dioxide through influence of electrical discharge at diminished pressure. FRANZ FISCHER, HANS KÜSTER AND KURT PETER. *Brennstoff-Chem.* 11, 300–4(1930); cf. *C. A.* 23, 3861, 4326.—By use of app. previously described, the dissocn. and the elec. efficiency were detd. for dry and wet CO_2 at various flow rates, pressures and current densities. The effects of these variations are shown graphically together with temp. variations in different parts of the discharge tube. The dissocn. of dry CO_2 reached a max. of 42% at 40–60 mm. Hg pressure, 2.0 kw. discharge and 100–150 l./hr. flow. It increased sharply to this point with increasing pressure and flow, then slowly decreased linearly with flow. Increasing c. d. also increased the dissocn., dry gas showing the greater effect. Recombination to reform CO_2 took place rapidly in the presence of H_2O vapor. Efficiency increased with increasing rates, as much as 18% efficiency being obtained at 550 l./hr., the remaining energy going into heat loss. Temps. varied between 700° and 1200° with current and pressures of 30–100 mm. Hg, increasingly linearly with the latter. Variations of rate or H_2O vapor had no effect with const. pressure and c. d. Little O_2 was found in the decompd. CO_2. Dissocn. was believed divided between thermal and elec. effects. F. W. JUNG

Preparation of a large-current quartz mercury-vapor lamp. TSUNESABURÔ ASADA. *Proc. Phys.-Math. Soc. Japan* [3], 12, 167–70(1930).—Novel features of this lamp include a vacuum-tight seal of an Fe-Ni electrode into the quartz and a brine-cooled steel anode which extends into the interior of the lamp, thereby keeping the temp. from rising too high. This lamp may carry a current of 20 amp. MALCOLM DOLE

The constricted mercury arc. R. H. CRIST. *J. Am. Chem. Soc.* 52, 4237(1930).—

Directions are given for making an arc that will run at 4–5.5 amps. and 20–5 v. per sq. cm. for over 30 hrs. with fairly const. intensity. J. H. MOORE

A geometrical analysis of open carbon arc phenomena. W. CRAMP AND A. P. JARVIS. *J. Inst. Elec. Eng.* (London) **68**, 1301–12(1930).—The behavior of a C arc is developed geometrically and proved experimentally. From this the conditions governing the musical arc are deduced and the growth of arc oscillations is traced. Geometrical methods are employed because no direct integration of the differential equations is possible. A. D. S.

Preparation of carbon for the electrical use. VI. Studies on pulverized carbon for the transmitter (3). GENKICHI ICHINOSE. *Rept. Osaka Ind. Research Lab., Japan* 11, No. 8(1930). F. I. NAKAMURA

The radiation distribution of antennae in vertical planes. R. M. WILMOTTE. *J. Inst. Elec. Eng.* (London) **68**, 1191–1204(1930).—Distribution in a vertical plane was obtained by measuring in an airplane the strength of a received signal from an excited antenna on the ground. Substantial agreement was obtained between theory and expt., the discrepancies increasing with the frequency. A. D. S.

Electrical porcelain. II. J. K. GILLETT. *Electrician* **105**, 588–9(1930); cf. *C. A.* **25**, 37.—This instalment deals with tests for porosity, the effect of glazes on mech. and thermal properties, and breakdowns caused by cementing. A brief bibliography is included. W. H. BOYNTON

Electrical resistance of Ni and permalloy wires as affected by longitudinal magnetization and tension (MCKEEHAN) **9**. Apparatus and operation for making hollow rubber articles by electrodeposition from aqueous rubber dispersions (U. S. 1,783,435) **30**. Apparatus for dehydrating petroleum emulsions by electric treatment (U. S. pat. 1,783,595) **22**. Crucibles (U. S. pat. 1,784,647) **1**. Ferricyanides (Ger. pat. 504,501) **18**.

Electric dry-cell battery. GEORGE W. HEISE and ERWIN A. SCHUMACHER (to National Carbon Co.). U. S. 1,784,592, Dec. 9. A cell is described with Zn and Cu electrodes, a Cu oxide depolarizer coöperating with the Cu cathode, a caustic alkali electrolyte in gel form and cellulosic fibers reënforcing the electrolyte gel.

Dry-cell electric battery cores. JOSEPH M. HENDERSON (to Burgess Battery Co.). U. S. 1,781,688, Nov. 18. Mech. features of manuf.

Electric storage battery. M. KUGEL. Brit. 332,660, May 3, 1929. Addnl. phosphoric acid required to maintain the strength of the electrolyte described in Brit. 280,197 (*C. A.* **22**, 2889) is supplied by introducing into the electrolyte a solid substance which will produce H_3PO_4 such as phosphates of Ca, Mg, Al, Ba, Zn, Cd or Pb (which may be in the form of tablets, sticks, balls or cubes), or solid metaphosphoric acid may be used, as may also products formed by adding small quantities of metal oxides to H_3PO_4. The solid material may also be used with H_2SO_4 for producing the electrolyte originally used in the battery.

Sealing on covers of storage batteries. HERBERT H. ALDRICH and JOHN L. RUPP (to Wubco Battery Corp.). U. S. 1,784,216, Dec. 9. A cover of bituminous compn. is applied to a container of the same material and the adjoining faces of the cover and container are joined by fusion of the edges and ironing of the joint.

Galvanic element. MANNESMANN LICHT A.-G. (Karl Stamm, inventor). Ger. 504,638, Apr. 14, 1926. The waste lye from the production of high % K salts in the K industry is used as the electrolyte.

Electrodeposition of gold. HEINRICH PAWECK and ROBERT WEINER. Austrian 119,022, Apr. 15, 1930. A bath is used contg. alkali or alkali carbonate and considerably higher proportions of $K_4Fe(CN)_6$ and Au than those hitherto taken, *e. g.*, $K_4Fe(CN)_6$ 200 and Au 20 g. per l. A high c. d., *e. g.*, 5 amps. per sq. dm., is also applied, and the bath is stirred and warmed in known manner. When insol. anodes are used, the bath is replenished with a salt prepd. by adding $HAuCl_4$ to a hot concd. soln. of $K_4Fe(CN)_6$, then adding Na_2CO_3, filtering off the pptd. Fe and crystg. the soln.

Apparatus for electrodeposition of metal on metal tubes. FRANCIS G. MARTIN and WILLIAM RAMSEY (to J. Stone & Co., Ltd.). U. S. 1,783,885, Dec. 2. Structural features.

Apparatus for electrodeposition of metals such as nickel, iron and copper. JACK HOLLINS (to Imperial Chemical Industries, Ltd.). U. S. 1,782,614, Nov. 25. Structural features.

Electroplating apparatus. CONSTANTINE G. MILLER. U. S. 1,781,791, Nov. 18. Structural features.

Chromium plating. JOHN F. K. MCCULLOUGH and BENJAMIN W. GILCHRIST (to *Ternstedt Mfg. Co.). U. S. 1,781,789, Nov. 18. With a Cr chloride plating bath there is incorporated an addnl. material such as $AlCl_3$ which combines with the OH ions to prevent deposition of Cr hydroxide on the articles being plated. Cf. C. A. 24, 791.*

Electrolytic cell for deposition of iron. ROBERT D. PIKE. U. S. 1,782,909, Nov. 25. Various details are given with reference to a cell with alternating anode and cathode compartments, and with disc cathodes mounted on a shaft for rotation and dipping into the electrolyte.

Electrolytic plant for making iron sheets or tubes or figured iron, with endless-band cathode and anode. ÖSTERREICHISCHE-ALPINE MONTANGES. Austrian 119,031, Apr. 15, 1930.

Removing salts from water, etc., by electrolysis. JEAN BILLITER. Austrian 119,209, Apr. 15, 1930. The liquid to be purified is supplied to the middle compartments of a 3-compartment cell series, the distance between the diaphragms limiting each middle compartment being less than 1 cm.

Tarnish-resisting coatings comprising chromium and silver. DANIEL GRAY, RICHARD O. BAILEY and WM. S. MURRAY (to Oneida Community, Ltd.). U. S. 1,782,092, Nov. 18. Articles are electroplated in a bath contg. a Ag compd. such as Ag chromate together with Cr sulfate and at least 3% of chromic acid, using an anode such as Pb and maintaining an excess of Ag salt in contact with the bath.

Refining aluminum electrolytically. PAUL L. HULIN (to Soc. anon. compagnie de produits chimiques et electrometallurgiques Alais). U. S. 1,782,616, Nov. 25. Refining is effected in an app. contg. 3 superposed layers in a state of fusion: an anode of a dense alloy of the metal to be extd. such as an alloy of Al with Cu, a halogenated bath such as cryolite, alumina, AlF_3 and BaF_2 forming the electrolyte, and a light metal such as pure Al forming the floating cathode, with a horizontal frame of refractory material or C surrounding the anode, a horizontal frame of insulating material contg. the electrolyte and a frame composed substantially of C surrounding the cathode and insulated from an outer metal shell.

Chlorine fixation or recovery in electrolytic processes. EDWIN O. BARSTOW (to Dow Chemical Co.). U. S. 1,781,830, Nov. 18. In the electrolysis of fused compds. such as NaCl and $MgCl_2$, Cl is exhausted while admitting air and the resulting mixt is treated with an agent such as SO_2 and water for selectively retaining the Cl.

Electrode (formed largely of corrugated sheet aluminum) for electrolytic condensers. RALPH D. MERSHON. U. S. 1,784,532, Dec. 9. Structural features.

Precipitating electrode for electric gas-cleaning plant. SIEMENS-SCHUCKERTWERKE A.-G. (Richard Heinrich, inventor.) Ger. 506,434, June 11, 1929. Addn. to 424,834.

Cathodes for electric discharge vessels. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger. 506,459, Apr. 2, 1926. In prepg. cathodes which are to be heated indirectly and comprise a metal coating on a non-conducting oxide, the finely powd. metal is pasted with a sufficiently viscous inert liquid and applied to the oxide, the liquid is evapd. and the powd. metal is sintered on. Electron-emitting substances may be included in the coating. Addnl. details are described.

Electric-furnace for heating metal articles. RANDAL E. TALLEY (to George J. Hagan Co.). U. S. 1,783,155, Nov. 25. Various details are described of a furnace with a hearth which may be tilted and simultaneously jarred. U. S. 1,783,156 relates to a rotary-hearth heat-treating app.

Electric furnace for melting aluminum, etc. FRANZ LINNHOFF (to Ajax Electrothermic Corp.). U. S. 1,782,359, Nov. 18. Details are given of a furnace the upper portion of which is heated by elec. induction and the lower portion of which is heated by resistance heating.

Electric resistance furnace adapted for hardening metals by nitrogenization. ADOLF FRY (to Nitralloy Corp.). U. S. reissue 17,874, Nov. 18. Reissue of original pat. No. 1,661,694 (*C. A.* 22, 1286).

High-frequency electric induction heating system for zone-hardening steel articles such as rolls. JAMES R. ADAMS. U. S. 1,783,764, Dec. 2. The speed of the heating operation is regulated by the rate of power input and the depth of penetration of the hardening heat is regulated by the frequency of the current and rate of power input.

Electrically heated furnace for annealing metal sheets, wire, etc. METALLGES. A.-G., H. VON FORSTER and E. LAY. Brit. 332,656, May 3, 1929. Structural features.

Electric-resistance muffle-furnace construction suitable for heat treating drills, etc. ARTHUR IMBERY (to Globar Corp.). U. S. 1,784,670, Dec. 9.

Charging apparatus for circular electric furnaces. PAUL L. J. MIQUET. U. S. 1,784,699, Dec. 9. Structural features.

Arc smelting furnaces. DEMAG A.-G. Ger. 506,303, Dec. 20, 1928. A furnace having a rotatable cover, through which the electrodes are carried, is provided with means for raising the cover before each rotation.

Electrically heated apparatus for roasting coffee, cocoa, ores, etc. ROBERT H. TALBUTT and FREDERICK A. ALLNER. U. S. 1,782,946, Nov. 25. Structural features.

Electric condenser. MICHAEL POLANYI and STEPHAN VON BOGDANDY. U. S. 1,784,611, Dec. 9. Alternate thin layers of materials such as metal and dielectric material are pptd. in quick succession on a common support such as a rotating drum (suitably by spraying). App. is described.

Electrolytic condensers. RALPH D. MERSHON. U. S. 1,784,674, Dec. 9. An electrolyte such as borax and H_3BO_3 soln. is held in a Cu vessel and filmed anodes such as Al are immersed in the electrolyte. Inactive parts are made of non-filming metal such as Cu and a unidirectional current may be passed through the electrolyte to electroplate out injurious metals. Various structural details are described.

Conditioning electric switches. ROBERT A. MILLIKAN and ROYAL W. SORENSEN (to Calif. Institute of Technology). U. S. 1,784,302, Dec. 9. Contacts, which may be formed of Cu or W, are mounted in a gas-tight chamber and the chamber is exhausted to a pressure lower than the pressure at which gases are conductive, an elec. potential is imposed on the contacts and they are opened to establish an arc between them, and expelled occluded gases are exhausted. U. S. 1,784,303 relates to power circuit interrupters which may be similarly prepd. and the electrodes of which are sufficiently free from occluded gases to have the capacity of producing a fractional cycle arc only when the electrodes are sepd. while carrying a power current.

Mercury-vapor lamps. DEUTSCH ENGLISCHE QUARZSCHMELZE GES. and THERMAL SYNDICATE, LTD. Brit. 332,744, July 22, 1929. In lamps open to the atm., escape of Hg vapor is prevented by causing it to pass into a vessel contg. a material which either absorbs or combines with it such as Au leaf or powder or Au-coated metal foil. Various structural details are described.

Electric incandescent lamps. PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN (to General Electric Co., Ltd.). Brit. 332,506, July 1, 1929. Parts of the lamp to be covered by the cap are roughened during sealing to secure adhesion to the cap (suitably by jets of acid fumes, by blowing powd. glass against the softened glass of the lamp or by introducing etching gases into some of the heating flames, use of P hydride, B hydride and boric acid esters being mentioned).

The Eberhard effect in relation to photographic photometry. N. VALENKOV. *Z. wiss. Phot.* **27**, 236–67(1930).—The Eberhard effect is in a high degree dependent upon the sharpness of the photographic picture. For the straight line portion of the H. and D. curve, the effect is proportional to the difference of the densities between the pictured object and the surrounding field. If the surface of the picture is large, the Eberhard effect shows an edge effect which is never wider than 1.5 mm. Pictures smaller than 3 mm. in diam. show increased densities through the Eberhard effect. The effect is independent of the form of the picture. Very fine grain photographic emulsions show no Eberhard effect. With increasing grain size, this effect increases. For x-rays there is almost no effect. Increase in density due to the Eberhard effect is in all cases very small. Development with metol-hydroquinone and KBr did not show any more difference in the effect than development with ferrous oxalate. The effect is independent of the intensity of the light source. It has little significance for both astrophotometry and spectrophotometry; for x-rays, especially, it has no significance whatever. A. P. H. TRIVELLI

Development of diazotypes or other treatments of films with gas. CELLOPHANE, SOC. ANON. Brit. 332,631, Feb. 21, 1929. Uniform treatment of films with NH_3 or other gas is facilitated by rolling up with the films a gas-permeable band of paper, cloth or the like. Various details of gas treatment and gas removal are also described.

Light-sensitive layer. JOHN EGGERT, RICHARD SCHMIDT and BRUNO WENDT (to Agfa Ansco Corp.). U. S. 1,782,259, Nov. 18. An ethylene deriv. forming *cis-trans*-isomerides, such as maleic acid or *trans*-dibenzoylethylene, is used for sensitizing.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Hydrates of oxides and of mineral salts. L. HACKSPILL AND A. P. KIEFFER. *Ann. chim.* [10], **14**, 227–82(1930).—With a view to detg. the mechanism of the reaction and to explaining, if possible, any existing anomalies, H. and K. studied the dehydration *in vacuo* of a series of hydrates of oxides and of mineral salts. The method used consisted in heating the hydrate *in vacuo* and measuring the loss of H_2O by reading the pressure established in the app. The values of the pressure and the temp. were recorded automatically. Dehydration curves for the substances studied are given. With hydrated Cr_2O_3 dehydration begins at ordinary temp. and continues gradually up to 550°, where it is complete. The curve obtained is characteristic of amorphous hydrates. Although analysis gave the formula $Cr_2O_3.3H_2O$ for the substance, it is a hydrate with a variable proportion of H_2O; it is a dry gel up to 26% H_2O. Therefore, it cannot be given the formula of a definite hydrate. An attempt to prep. $Bi(OH)_3$ by pptg. a soln. of $Bi(NO_3)_3$ with NH_4OH in the cold gave a product with the formula $(Bi_2O_3)_2.N_2O_5.H_2O$. Since other attempts to prep. the hydroxide were unsuccessful, H. and K. state that the existence of this compd. is very doubtful. Orthoboric acid, $B_2O_3.3H_2O$, is stable up to 90°. At 100° the decompn. becomes explosive and 95% of the total H_2O is lost, forming B_2O_3 contg. a little H_2O of adsorption. All the H_2O is gone at 250°. Only this third part of the curve is reversible. Metaboric acid, $B_2O_3.H_2O$, was prepd. by dehydrating ortho-

boric acid in a current of H_2O vapor at 135°. The dehydration curve is analogous to that of orthoboric acid, with the exception that the crit. temp. of dehydration is higher, the difference being due to the induction period. Both acids are perfect hydrates. $BeO.H_2O$ loses no H_2O up to 190°. At 190–200° there is a short induction period, followed at 200° by a rapid decompn. and loss of 80% of the H_2O present. Between 220° and 700° the rest of the H_2O is removed. This is H_2O of adsorption, and this part of the curve is not reversible. For each max. temp. at which the substance was heated, there was obtained an adsorption curve which showed that the higher the temp. the less the adsorption for a given temp. This can be explained only by a change in the phys. state of the substance by polymerization. BeO when heated alone does polymerize, and its state of polymerization is more advanced as the temp. is raised. Therefore $BeO.H_2O$, once dehydrated, cannot be formed again. $CdO.H_2O$ is stable up to 120°. There is then a period of induction followed by rapid dehydration from 160° up. Eighty-eight % of the H_2O is lost. Some of the H_2O remains fixed (as H_2O of adsorption) and is removed slowly up to 600°. At the same time polymerization of the CdO occurs. $ZnO.H_2O$ is less stable. *In vacuo* at 20° $ZnO.0.16H_2O$ is formed, the H_2O being fixed by adsorption. Dehydration thereafter is slow and continuous, and complete at 550°. Polymerization occurs here also, so that $ZnO.H_2O$, once dehydrated, cannot take up H_2O to give $Zn(OH)_2$. With $MgO.H_2O$ dehydration begins at 300° and is rather rapid. Ninety % of the H_2O is lost, and the remainder is removed gradually between 360° and 700°. H. and K. note that artificial brucite, freshly prepd., is dehydrated more easily than natural brucite. $Na_2O.B_2O_3.4H_2O$ loses some of the adhering H_2O at ordinary temp. The hydrate is then stable up to 110°. After a short induction period dehydration continues at 120° with a loss of 50% of the H_2O, giving $Na_2O.B_2O_3.2H_2O$. The rest of the H_2O is lost between 130° and 150°. The last 2 H_2O play a role entirely different from that of the first 2. They must enter into the constitution of the borate, and are "H_2O of semi-constitution." $Na_2O.B_2O_3.4H_2O$ should therefore be written $[Na_2O.B_2O_3.2H_2O].2H_2O$. The monoborates come from the acid $B_2O_3.3H_2O$ or H_3BO_3, the formula of orthoboric acid. Therefore they are not metaborates, as has been assumed previously, but diacid salts of orthoboric acid. $Na_2O.B_2O_3.5H_2O$ was prepd. The dehydration curve showed that 20% of the H_2O is fixed in an unstable manner, and that the salt is $Na_2O.B_2O_3.4H_2O$, to which adheres some of the mother liquor of the soln. from which it was crystd. (cf. Atterberg, *Z. anorg. Chem.* **48**, 371(1906) and Dukelski, *Ibid* **50**, 1(1906)). The dehydration curve of borax has 3 parts. From 20° to 60° there is an induction period, followed by abrupt, almost explosive, decompn. of the hydrate at 60° with loss of 80% of the H_2O. The last 20% of the H_2O is removed with difficulty; dehydration is gradual and is complete at 400°. The last 2 H_2O must enter into the constitution of the salt. The formula of borax is therefore $[Na_2O.(B_2O_3)_2.2H_2O].8H_2O$. The dehydration curve of $Na_2O.(B_2O_3)_2.5H_2O$ shows a horizontal part followed by a slow decompn. which becomes explosive at 120°. Sixty % of the H_2O is lost. The remaining 40% is removed slowly; the salt is completely dehydrated at 400°. It has 3 H_2O of hydration and 2 H_2O of semi-constitution. $Na_2O.(B_2O_3)_2.4H_2O$, a borate called kernite, is stable below 60°; at this point 32% of the H_2O is lost abruptly. The curve then shows a level section up to 116°, at which point 18% of the original H_2O is lost. The remaining $2H_2O$ are removed with more difficulty, and dehydration is not complete until the temp. is above 400°. The salt therefore has 2 H_2O of crystn. and 2 H_2O attached in a different way. The 2 abrupt losses of H_2O indicate that the salt is a mixt. of 2 hydrates. Further study led H. and K. to the conclusion that kernite is a mixt. of 3 hydrates in the proportion: $4[Na_2O.(B_2O_3)_2.10H_2O]$, $6[Na_2O.(B_2O_3)_2.5H_2O]$, $15[Na_2O.(B_2O_3)_2.2H_2O]$. The mixt. of these 3 hydrates forms a homogeneous, transparent crystal. $K_2O.(B_2O_3)_2.4H_2O$ is stable up to 100°. At this temp. dehydration occurs abruptly with removal of 50% of the total H_2O. The last 2 H_2O are removed gradually up to 400°, and are therefore H_2O of semi-constitution. $Cs_2O.(B_2O_3)_2.5H_2O$ is stable up to 70°, and then loses 60% of its H_2O. The other 2 H_2O are lost gradually between 70° and 400°, and are therefore H_2O of semi-constitution. The alk. diborates should be written $[M_2O.(B_2O_3)_2.2H_2O].nH_2O$. They come from an acid with the formula $(B_2O_3)_2.3H_2O$. $Na_2O.(B_2O_3)_2.10H_2O$ is stable up to 75°, where dehydration begins and continues until 80% of the H_2O has been lost. The remaining 2 H_2O are removed slowly up to 350°, and therefore enter into the constitution of the mol. $K_2O.(B_2O_3)_2.8H_2O$ is stable up to 105°, where 75% of the H_2O is lost. The remaining 2 H_2O are removed slowly, and are H_2O of semi-constitution. The formula should therefore be written $[K_2O.(B_2O_3)_2.2H_2O].6H_2O$. $Rb_2O.(B_2O_3)_2.8H_2O$ is stable up to 80°. An induction period is followed by rapid dehydration at 100° and loss of 6 H_2O. The other 2 H_2O are removed gradually be-

tween 120° and 300°, and are H_2O of semi-constitution. $Cs_2O.(B_2O_3)_5.8H_2O$ is stable up to 70°, where 6 H_2O are lost. The other 2 H_2O are H_2O of semi-constitution. All the pentaborates therefore probably contain 2 H_2O of constitution and the formula should be written $[M_2O.(B_2O_3)_5.2H_2O].nH_2O$. They are derived from an acid $(B_2O_3)_5.3H_2O$ or $H_3B_5O_9$. $MgSO_4.7H_2O$ begins to lose H_2O at ordinary temp. *in vacuo*. After an induction period, the loss is more rapid and 5 H_2O are lost, giving $MgSO_4.2H_2O$. The remaining 2 H_2O are removed slowly in 2 steps, which would indicate the existence of $MgSO_4.H_2O$. This hydrate has 5 H_2O of hydration and 2 H_2O of semi-constitution, which are combined differently. At ordinary temp. *in vacuo* $CoSO_4.7H_2O$ loses 5 H_2O. The remaining 2 H_2O are removed slowly between ordinary temp. and 320°, and are H_2O of semi-constitution. $NiSO_4.7H_2O$ behaves very much as the Co salt. Dehydration of $FeSO_4.7H_2O$ *in vacuo* begins at ordinary temp. but is not very rapid When 1.2 H_2O remain, there is a change in the direction of the curve and the rest of the H_2O is removed more slowly. A more exact study showed that because the rate of dehydration is very slow, $FeSO_4.2H_2O$ begins to decomp. in the presence of $FeSO_4.7H_2O$. This explains the value $FeSO_4.1.2H_2O$. The last 2 H_2O are H_2O of semi-constitution. With $BeSO_4.4H_2O$ dehydration begins at 60° and after an induction period becomes rapid at 90° with loss of 50% of the H_2O. Dehydration is then slow and complete only at 320°. The 2 H_2O of semi-constitution seem to be fixed with different affinities, for the curve indicates the possibility of $BeSO_4.H_2O$. $MnSO_4.4H_2O$ has a period of induction beginning at ordinary temp. The reaction is rapid above 60° and $MnSO_4.H_2O$ is formed. The last H_2O is removed slowly between 100° and 250°, and is H_2O of semi-constitution. Dehydration of $CuSO_4.5H_2O$ begins at ordinary temp. *in vacuo*. The period of induction lasts up to 70°, where dehydration becomes rapid, giving $CuSO_4.H_2O$. The pressure then remains const. up to 180°, where the last H_2O is removed. The salt contains 5 H_2O of hydration. For $3CdSO_4.8H_2O$ the period of induction begins at ordinary temp. and continues up to 80°, where dehydration is rapid, giving $CdSO_4.H_2O$. The pressure remains const. up to 105°, where the last H_2O is removed. A little H_2O of adsorption is held up to 200°. With $CaSO_4.2H_2O$ there is no dehydration up to 60°, where the induction period begins. At 80° dehydration is rapid, and 2 H_2O of hydration are lost. Only a little H_2O of adsorption (0.1 H_2O) remains at 100°, and is lost between 100° and 150°. The 2 H_2O are H_2O of hydration. $Al_2(SO_4)_3.18H_2O$ loses 2 H_2O *in vacuo* to give $Al_2(SO_4)_3.16H_2O$, which is stable up to 50°. After an induction period, dehydration becomes rapid above 70° and gives $Al_2(SO_4)_3.6H_2O$. The remaining 6 H_2O (H_2O of semi-constitution) are removed slowly between 100° and 450°. Violet Cr sulfate, $Cr_2(SO_4)_3.18H_2O$, loses 9 H_2O *in vacuo* without heat, giving $Cr_2(SO_4)_3.9H_2O$, which is stable up to 80°. The induction period then occurring continues up to a little above 100°, where dehydration becomes rapid and results in the formation of $Cr_2(SO_4)_3.3H_2O$. The last 3 H_2O are removed slowly and are H_2O of semi-constitution. A bend in the curve above 200° corresponds to $Cr_2(SO_4)_3.2H_2O$. The green Cr sulfate, $Cr_2(SO_4)_3.6H_2O$ (see Recoura, *Bull. soc. chim.* [3], 7, 200(1892)), loses 6 H_2O slowly over the interval from ordinary temp. up to 400°. These 6 H_2O are H_2O of constitution. Above 400° the salt begins to decompose. The violet sulfate dried at 100° gives a green powder with 6 H_2O. This powder does not give the same dehydration curve as the preceding Cr sulfate, and therefore the 2 are not identical. The one obtained from the violet salt is partially dehydrated $Cr_2(SO_4)_3.9H_2O$. For $CuSO_4.K_2SO_4.6H_2O$ the induction period is followed by rapid dehydration at 60°, giving $CuSO_4.K_2SO_4.2H_2O$. The last 2 H_2O are lost at 100°, and dehydration is complete at 120°. The 6 H_2O are H_2O of hydration. $ZnSO_4.K_2SO_4.6H_2O$ behaves as the preceding salt and is a perfect hydrate. Dehydration of $Al_2(SO_4)_3.K_2SO_4.24H_2O$ begins at ordinary temp. *in vacuo*, and after an induction period becomes rapid at 70° with loss of 18 H_2O. The last 6 H_2O behave like H_2O of semi-constitution, and dehydration is complete at 400°. The examn. of the dehydration curves has given valuable information as to the state in which the different mols. of H_2O are fixed. On the basis of the results, H. and K. classify them in 5 groups, instead of the 4 generally accepted: (1) H_2O of occlusion, which is found between the cryst. leaflets in the state of a satd. soln. Removal of this H_2O is continuous but slow. (2) H_2O of adsorption, conditioned by the state of the substance. It is found on the surfaces of the crystals; when the latter are infinitely small, one obtains gels. Removal of this H_2O is slow and continuous, but varies with the concn. (3) H_2O of crystn. which, being part of a cryst. lattice, involves by its removal the disintegration of the crystal. Its removal occurs abruptly at a fixed temp., which varies slightly with the conditions of the expt. (4) H_2O of semi-constitution, which seems to be an integral part of the mol. although its removal, however difficult, does not involve the decompn.

of the anhyd. salt. (5) H_2O which has always been called "water of constitution." It cannot be eliminated without complete breaking-up of the mol. of which it is a part. This H_2O cannot be detected by the method used in these expts., but can be obtained by difference. The same salt may contain 2 or more of the 5 varieties of H_2O just mentioned. One or more mols. of H_2O may pass from one method of fixation to another, *e. g.*, from adsorption to crystn., and *vice versa*. The same mol. of H_2O may be classed differently according to the point of view. The 3 H_2O of boric acid and the 2 or 3 H_2O of orthophosphoric acid are H_2O of crystn. according to the definition of H. and K., but from the purely chem. point of view it is difficult not to consider them as H_2O of constitution. The results show that the reversibility of dehydration is far from being as general as supposed by Debray. This study has not definitely settled the problem of the constitution of hydrates, but it has permitted a better interpretation of phenomena known for a long time. It has enabled the authors to establish or confirm the existence of certain definite hydrates and that of a basic nitrate of Bi. LOUISE KELLEY

The anhydrous lower bromides of titanium. RALPH C. YOUNG AND WALTER C. SCHUMB. *J. Am. Chem. Soc.* **52**, 4233–9(1930).—*Ti tribromide* (I) is obtained as nonvolatile, blue-black crystals by reduction of $TiBr_4$ (II) with H in a "hot-cold" tube. Above 350° I reacts rapidly with HBr, forming II and H. At 400° I decomposes to II and *Ti dibromide*. This latter compd. is black, very reactive, ignites on exposure to moist air and dissolves in H_2O with evolution of H. Heated above 500° decompn. to Ti and II ensues. Above 160° reaction with HBr gives I and II. Ti reacts with HBr forming, at 300°, the lower halides, at 450°, chiefly II. At 300° II in a sealed tube with Ti, Hg or Ag is partially reduced to I. Dissolved in C_6H_6 II is reduced to I by Ag and Hg. In the latter case the reaction is practically quant. B. A. SOULE

Cupric perchlorate. R. PORTILLO AND L. ALBERTOLA. *Anales soc. españ. fís. quím.* **28**, 1117–24(1930).—$Cu(ClO_4)_2$ was prepd. by the action of $HClO_4$ on $CuCO_3$. Crystn. gives pure $Cu(ClO_4)_2.7H_2O$; dried over P_2O_5 it forms $Cu(ClO_4)_2.6H_2O$. Hydrates contg. 4 and 2 H_2O were also prepd. With the hexahydrate $d_4^{23} = 2.225$, soly. 54.3%, mol. heat of soln. −4.6 cal., heat of formation in soln. +64.7 cal. A table of degrees of cryoscopic dissociation is given. E. M. SYMMES

The cupramines (II). Amines of cupric perchlorate. R. PORTILLO. *Anales soc. españ. fís. quím.* **28**, 1125–44(1930); cf. *C. A.* **24**, 308.—$Cu(ClO_4)_2.4NH_3.2H_2O$, $Cu(ClO_4)_2.4NH_3$, $Cu(ClO_4)_2.6NH_3$, $Cu(ClO_4)_2.5NH_3.2H_2O$, $Cu(ClO_4)_2.4NH_3.H_2O$, $Cu(ClO_4)_2.4NH_3.2H_2O$ and $3Cu(ClO_4)_2.10NH_3$ were prepd., the last 4 being new compds. For each, the *d.*, soly., cryoscopic dissocn., and heat of soln. were detd. E. M. S.

The polyiodides of cesium. II. Iodine and cesium iodide. T. R. BRIGGS. *J. Phys. Chem.* **34**, No. 10, 2260–6(1930); cf. *C. A.* **24**, 5248.—The necessary data for construction of the phase diagram for I_2-CsI have been detd. from 60° up to the b. p. of the satd. melt (303°). B. ps. of mixts. of known compn. together with analyses of the melt at known temps. constitute the exptl. criteria. The eutectic temp. for 18 mol. % CsI is fixed at 71.5 ± 0.1°. The presence of 4 solid phases I_2, CsI_4, CsI_3 and CsI is confirmed, but none of these polyiodides is stable at the m. p. A pronounced change of phase is detected at 208–211°, below which temp. the compd. $CsI.I_2(CsI_3)$ appears. H. R. MOORE

The preparation of sulfur hexafluoride and some of its physical properties. WALTER C. SCHUMB AND E. LEE GAMBLE. *J. Am. Chem. Soc.* **52**, 4302–8(1930).—F, prepd. by electrolysis of KHF_2 in a Monel metal generator with graphite anode, formed SF_6 on interaction with S. The properties of the purified product were: vapor pressure of the solid, 760 mm. at −63.8°; m. p. −50.8 ± 0.2°; vapor d. at 20° and 753.5 mm., 6.093 g./l.; relative d. (air = 1), 5.10$_6$. B. A. SOULE

formed by NH_2OH are analogous to those formed by NH_4OH. With Pt there is a ppt. like that formed from H_2PtCl_6 and NH_2OH. With Cu characteristic ppts. are formed. NH_2OH and colloidal $Cu_2Fe(CN)_6$ give a compd. of green fluorescence in the dark and blue fluorescence in sunlight. E. M. SYMMES

Quantitative method of spectrographic analysis. PIERRE URBAIN. *Bull. soc. chim.* [4], **47**, 1183–8(1930).—See *C. A.* **24**, 2961. E. C. K.

Quantitative analysis of steels by spectrum analysis. F. TWYMAN AND A. A. FITCH. *Engineering* **130**, 635–6(1930).—See *C. A.* **24**, 5256. E. C. K.

Historical notes on the Reinsch test (for arsenic). HENRY LEFFMAN. *Analyst* **55**, 684(1930).—The original date of publication and some of the earliest papers mentioning the test are given. W. T. H.

Determination of bismuth in lead ores by internal electrolysis. ELLA M. COLLIN. *Analyst* **55**, 680–2(1930).—The following method is satisfactory for most ores, although in some cases special treatment may be necessary for the attack of the ore. Boil 1–2 g of the finely crushed sample for 10 min. with 25–50 cc. of concd. HCl. If the action is slow add about 1 g. of Zn and heat a little longer. Evap. the soln. to dryness and bake on the hot plate to remove most of the free HCl. Take up the residue in 5 cc. of 7.5 *N* HNO_3. Dil. with hot water, filter and wash with hot 5% HNO_3. If any considerable residue other than siliceous material remains, it is best to give it another treatment with HNO_3. To the soln. add 2% $KMnO_4$ until it is no longer decolorized, to make sure that all Sb is quinquevalent. Add 1 g. of $NH_2OH.HCl$ and electrolyze in the internal electrolysis app. at 80–85° (cf. Collin, *C. A.* **24**, 3726). Dissolve the combined ppts. of Bi and Cu in HNO_3 and sep. the Cu from Bi in the usual manner by means of NH_4OH and $(NH_4)_2CO_3$. Dissolve the Bi ppt. in 7.5 *N* HNO_3 and deposit the Bi by internal electrolysis. If the Bi content is very low the colorimetric detn. of Bi with KI is preferable to the second electrolysis. W. T. H.

Examination of bismuth for tellurium. H. TÖPELMANN. *Z. anal. Chem.* **82**, 284–5(1930).—Te frequently occurs as an impurity in metallic Bi and it is sometimes desirable to det. quickly the approx. Te content of a sample of Bi. If more than 0.001% of Te is present, it is easy to detect and det. semi-quantitatively by means of spectral analysis. Exact details are given for carrying out the test. If less than 0.001% of Te is present, the $SnCl_2$ test is useful. In many cases it is desirable to combine the 2 methods. Expts. with different electrodes are described and the influence of foreign elements on the results is discussed. W. T. H.

Electrodeposition of copper from solutions containing tartaric acid and chloride. HANS HÖLEMANN. *Z. anal. Chem.* **82**, 273–6(1930).—In a previous paper (*C. A.* **24**, 4728) H. has shown that the discharge potentials of Cu and Sb lie so close together that it is impossible to sep. them in HCl soln. By adding tartaric acid, whereby the Sb is converted more completely into a complex anion than it is in the presence of HCl alone, it is now shown that good deposits of Cu can be obtained in the presence of Sb but, unfortunately, Sb begins to deposit before the deposition of the Cu is complete. W. T. H.

Some observations on the estimation of silicon in pig and cast iron. H. W. KEEBLE. *Iron and Steel Ind. and Brit. Foundryman* **3**, 367–8(1930). C. H. LORIG

Iodometric determination of thallium in the presence of ferric iron. The determination in the cadaver. R. FRIDLI. *Deut. Z. ges. gericht. Med.* **15**, 478–88(1930).—Finely ground cadaver (50–100 g.) was digested in concd. NaOH (10 g.) to a homogeneous paste and ignited over a free flame. The cooled ash was then neutralized, made slightly acid with H_2SO_4 and heated on the water bath for 30 min. The mixt. was filtered so that the filtrate plus washings did not exceed 200 cc. Twenty cc. of this filtrate in a 50-cc. beaker was treated with Br-H_2O (few drops); and 2 g. $Na_2HPO_4.12H_2O$ and 5 cc. of 50% H_3PO_4 were added. After 10 min., 0.5 g. KI was added. In the presence of 0.1 mg. Tl the soln. turned yellow, 0.2 mg. produced a slight turbidity and with 0.5 mg. or more there was a marked sepn. of TlI. If Fe^{+++} is present, 10 g. $Na_2HPO_4.12H_2O$ and 20 cc. of 50% H_3PO_4 are added to the remaining 180 cc. of filtrate. Oxidation was produced by Br-H_2O, excess of which was avoided by the addn. of 2 cc. of 5% phenol soln. After the iodometric titration, the TlI was filtered off, dissolved by Cl-H_2O, the soln. evapd. to dryness and Tl detd. in the residue. FRANCES KRASNOW

Determination of small quantities of oxygen in gases. H. R. AMBLER. *Analyst* **55**, 677–80(1930).—The combustion of H_2 in excess of O_2 with the aid of a red-hot Pt wire is a well-known method for detg. H_2 (Dennis and Hopkins). The expts. here described are based on the reverse procedure for the detn. of O_2. In mixts. contg. only O_2, H_2 and N_2, the method is suitable for all proportions of O_2 up to about 4%, which is the explosion limit. The results are accurate within about 0.01% of the total vol. of

gas used in the test. If oxides of C are present, however, the accuracy is reduced. W. T. H.

A modification of iron oxide analysis using diphenylamine indicator. WALLACE K. GIBSON. *Rock Products* 33, No. 22, 66(1930).—The use of a "titrating solution" contg. 100 cc. 71% H_3PO_4 and 434 cc. concd. H_2SO_4 per l. is recommended. Cf. *C. A.* 23, 5557. RAYMOND WILSON

Potentiometric study of the reaction between ferrocyanide and sodium nitrite. JESÚS VÁSQUEZ ROMÓN. *Anales soc. españ. fis. quím.* 28, 1045–9(1930).—In the reaction $Na_4Fe(CN)_6 + NaNO_2 + H_2SO_4 = Na_3Fe(CN)_6 + Na_2SO_4 + NO$ there is a break in the potential curve at the equiv. point. It is possible to det. $NaNO_2$ with $Na_4Fe(CN)_6$ or *vice versa*. E. M. SYMMES

A Kjeldahl method for determining nitro nitrogen in aromatic compounds. M. WEIZMANN, J. YOFE AND B. KIRZON. *Z. physiol. Chem.* 192, 70–2(1930).—The method is based on reduction of the NO_2 group by Zn dust, and is applicable to micro detns. In a 100-cc. Kjeldahl flask treat 0.1–0.2 g. of the dry substance with 5 cc. fuming H_2SO_4 (contg. 7% SO_3) and 2 g. of Zn dust. Avoid too rapid development of heat by adding the Zn slowly. A strong odor of H_2S is soon apparent. Place a small funnel in the neck of the flask and allow the mixt. to stand several hrs., preferably overnight. Add a few crystals of $CuSO_4$ and K_2SO_4 and gradually heat the flask. After 5–6 hrs. apply the full flame and continue heating 6–20 hrs. until the mixt. is decolorized completely. When cool rinse the flask with 10 cc. H_2O, add an excess of 33% NaOH and 10 cc. more H_2O, distil the NH_3 as usual into 10–20 cc. 0.1 *N* H_2SO_4 and titrate the excess acid with 0.1 *N* NaOH and dimethyl red. The quantity of Zn used should be at least 4 times the theoretical. By this procedure good results were obtained in the analysis of *o*- and *p*-$O_2NC_6H_4OH$, α-$C_{10}H_7NO_2$ and picric acid. A. W. DOX

Determination of ethylene oxide in gas mixtures. W. DECKERT. *Z. anal. Chem.* 82, 297–307(1930).—Mixts. of C_2H_4O (*A*) and CO_2 are used under the name of *T-gas* for killing insects. When *A* reacts with HCl glycol chlorohydrin is formed, one mol. of *A* reacting with 1 of HCl. The reaction can be made the basis of a volumetric method for detg. *A* in a gas mixt. By passing the gas through a 22% NaCl soln. in 0.1 *N* HCl all of *A* is absorbed and excellent results are obtained by titrating the excess HCl if the soln. is first heated; or the diminution in vol. of the gas after treatment with HCl-NaCl soln. can be used as basis for the analysis. For a practical analysis of air that has been sprayed with *A*, pass a slow stream of the air (1 l. in 4 min.) through 0.1–0.001 *N* HCl until at least 0.44 mg. of *A* has been absorbed. Then heat the soln. to about 70° and titrate the excess acid with NaOH, methyl orange being used as indicator. One cc. of 0.1 *N* HCl = 4.4 mg. of *A*. W. T. H.

Determination of amino acids with the aid of physicochemical methods. H. LEY AND B. ARENDS. *Z. physiol. Chem.* 193, 131–44(1930).—The Cu complexes of various amino acids show more or less characteristic absorption in the visible spectrum. Those of aliphatic monoamino acids have an intense blue color; those of simple diamino acids, *e. g.*, $NH_2CH_2CHNH_2CO_2H$, are reddish violet. These salts undergo practically no electrolytic dissocn., since the metal is linked to the amino acid by both primary and secondary valences. Except at very high dilns. the molar extinction, measured in a spectral photometer with monochromatic light, is independent of the concn. Extinction curves are given for the Cu complexes of glycine, alanine, $Me_2CNH_2CO_2H$, $NH_2CH_2CH(NH_2)CO_2H$, proline and hydroxyproline. The presence of alkali salts, *e. g.*, NaCl, has practically no influence. Dissociable Cu salts, however, *e. g.*, $CuSO_4$ and $CuCl_2$, greatly diminish the extinction coeffs. of the complexes. For mixts. of 2 complexes the extinction is the sum of the sep. extinctions; hence the concn. of the 2 components can be calcd. from a simple equation. Detns. made in this way of several mixts. of glycine and alanine gave results in close agreement with the theoretical. A. W. DOX

Determination of naphthalene in mixtures with phenols and anthracene. MARIANO MARTÍNEZ CASTILLA. *Anales soc. españ. fis. quím.* 28, 1084–8(1930).—Phenols do not interfere with formation of picrates of hydrocarbons unless more than 50% are present. For the Knublauch method (*C. A.* 11, 3198; 13, 70) to give quant. results with hydrocarbons it is necessary to take into consideration the fact that the 0.002% picric soln. should be added in the necessary quantities to eliminate by washing the calcd. excess of picric acid. Results obtained with anthracene were unsatisfactory. E. M. S.

Extension of micrometric analytical methods to the determination of lactose. J. MA. CLAVERA AND F. MORENO MARTÍN. *Anales soc. españ. fis. quím.* 28, 1066–79(1930).—The Hagedorn-Jensen method (*C. A.* 17, 2721) of glucemia detn. is used in connection with a table prepd. by analyzing known solns. of lactose. The method requires only 0.5 hr. and 0.5 cc. of sample. E. M. SYMMES

The carbazole reaction for carbohydrates and related compounds. JOSEPH S. HEPBURN AND MICHAEL LAZARCHICK. *Am. J. Pharm.* **102**, 560–4(1930).—The test may be made in 3 different ways: (1) Place 1 cc. of the soln. to be tested in a test tube, add 2 cc. of concd. H_2SO_4 (sp. gr. 1.84), mix, cool to room temp., add 0.1 cc. of 0.5% soln. of carbazole in alc., mix, cool to room temp., place in a bath of boiling water and heat for 10 min. (2) Proceed as in (1) but increase the vol. of concd. H_2SO_4 used to 4 cc. (3) Place 1 cc. of the soln. to be tested in a test tube, add 4 cc. of concd. H_2SO_4, mix, cool to room temp., place in a bath of boiling water, heat for 10 min., remove from the bath, cool to room temp., add 1 cc. of distd. water, mix, again cool to room temp., add 0.1 cc. of the alc. soln. of carbazole, once more cool to room temp., place in a bath of boiling water and heat for 10 min. This test has been applied, in all 3 modifications, to freshly prepd. aq. solns. of the following carbohydrates and closely related compds.: monosaccharides: xylose, dextrose, galactose and levulose; disaccharides: maltose, lactose, sucrose; polysaccharide: starch (corn); glucosides: amygdalin, digitonin, esculin, phlorhizin, salicin; hydroxy acids: gluconic acid (as its Ca salt), mucic acid (as its NH_4 salt), β-hydroxybutyric acid, acetoacetic acid (as its Et ester). With the exception of β-hydroxybutyric acid (0.842% aq. soln.), xylose, esculin and salicin (0.5%), phlorhizin 0.1% and mucic acid (0.1%), the initial expt. with each compd. was made with 1% aq. soln. Each of the 17 compds. was also tested at concns. of 0.1, 0.01, 0.001 and 0.0001%. The results are recorded in a table which shows for each compd. the color (if any) given in each procedure at each of the specified concns. The colors usually produced by solns. contg. 0.1% or less of the carbohydrate or related compd. were blue, purple, lilac, or violet. With a single exception, green appeared only when procedure (2) was used; it then was yielded by lactose, esculin and salicin in concns. of 0.01% or less, and by the 4 hydroxy acids in concns. of 0.1% or less. Procedures (1) and (3) tended to give results in agreement with each other, but differing at times from those given by procedure (2). The carbazole reaction by all 3 modifications were entirely neg., *i. e.*, its limit had been exceeded and no color formed, with 0.0001% solns. of the 4 monosaccharides, sucrose, cornstarch, digitonin, phlorhizin and mucic acid, and with 0.001% solns. of maltose, β-hydroxybutyric acid, and acetoacetic ester, while the reaction was still pos. with 0.0001% solns. of esculin, salicin and Ca gluconate. With lactose and amygdalin, the limit of the test varied with the procedure, the limit being exceeded with 0.0001% solns. in procedure (1) and with 0.001% solns. in procedures (2) and (3). The carbazole reaction may serve as a group reaction. However, the colors produced by any one of the compds. used were not sufficiently characteristic to distinguish it from the other compds. in the group studied. W. G. GAESSLER

Radiometric microdetermination of sugar. RUDOLF EHRENBERG. *Biochem. Z.* **226**, 250–2(1930).—In sugar analysis according to Hagedorn-Jensen's method, $K_4Fe(CN)_6$ is detd. radiometrically, whereby a difference of 10^{-5} mg. glucose can be detected. Expts. were carried out with known amts. of glucose in concns. ranging from 1.5 to 9×10^{-3} mg. Of these solns. 0.2 cc. was mixed in centrifuge tubes with 0.5 cc. of a mixt. of 0.01 *N* $K_3Fe(CN)_6$ and Na_2CO_3 and kept 15 min. in a boiling water bath. After cooling 0.5 cc. 0.002 *N* $Pb(NO_3)_2$ charged with ThB was added. (The $Pb(NO_3)_2$ soln. contains 0.5 cc. glacial AcOH per 20 cc.). After centrifuging, 0.5 cc. is removed, evapd and tested electrometrically. Controls with H_2O are carried out at the same time. The activity is then expressed in equiv. glucose quantities. For detns. on blood, 0.1 cc. is placed on a small wad of dry, alc.-extd. cotton packed in the bottom of a small test tube. To the dry blood is added 1 cc. 96% alc. and after 1 hr. also 1 cc. H_2O. After some time this is transferred to a 5 cc. vol. flask, and the cotton re-extd. with 1 cc. H_2O twice. The vol. is made up to 5 cc., 0.2-cc. samples being used for the detn. as already described. S. MORGULIS

The differentiation of cyclic monophenols and monoamines from polyphenols and polyamines. AUGUSTIN MARENZI. *Ann. de Farm. y Bioquim.* **1**, 99–105(1930).—M. describes a method for the differentiation of these compds. by the use of phenol reagent (phosphotungstic and phosphomolybdic reagent) and uric acid reagent (phosphotungstic reagent). Methods for the prepn. of the reagents are described in detail. B. S. LEVINE

A reaction for distinguishing between neutral and basic lead acetate. WALTER A. MUNDT. *Ann. de Farm. y Bioquim* **1**, 119–20(1930).—H_2O_2 is used as the reagent. In the presence of basic lead acetate (as little as 1–3000) a yellow lead peroxide is formed. No reaction takes place with the neutral compd. B. S. LEVINE

Tests for madar juice (Calotropis gigantea) and for snake venom. D. N. CHATTERJI. *Analyst* **55**, 683–4(1930).—Digest the suspected material with abs. alc. for an hr. under a reflux condenser. Distil the ext. with the addn. of a little 1/3 *N* H_2SO_4. The

distillate has a characteristic fruity odor which should be compared with that obtained from a sample known to be madar juice. To the residue obtained from the extn. with alc., add concd. HCl; if madar juice is present, a greenish blue color develops, which changes to brown and violet and which disappears on heating or on standing. To detect snake venom, the serum test which depends upon making an aq. soln. and injecting it into a frog, is recommended. If the frog dies det. the lethal dose of ext. and mix it with twice its vol. of freshly prepd. antivenine (serum immunized against cobra and Russell's viper venom) and incubate for 1 hr. Then treat two more frogs, side by side, one with a lethal dose of the untreated ext. and the other with the same dose which has been immunized. W. T. H.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Pseudo-eutectic textures. WALDEMAR LINDGREN. *Econ. Geol.* **25**, 1–13(1930).—The peculiar intergrowth of sulfide minerals which simulate the eutectic texture in metals is held by L. to indicate replacement, rather than simultaneous deposition, as often believed. Material selected for study was an intergrowth of tennantite, $Cu_6As_2S_6$, and stromeyerite, $(Cu, Ag)_2S$. The intergrowths are described in detail, and structural features shown by figures. L. shows that in the pseudo-eutectic texture, stromeyerite replaces tennantite. Other examples of such pseudo-eutectic textures are given, all the minerals replaced being soft and no cases being known among harder minerals. It is thought that the pseudo-eutectic texture always represents a replacement of one soft mineral by another, in its typical development independent of structural lines in the host. Where the guest mineral assumes a microcryst. structure there are no pseudo-eutectic intergrowths. Locally either of the minerals may be in excess. Replacement of stromeyerite by Ag is also described. ALICE W. EPPERSON

Occurrence and relations of alabandite. D. F. HEWETT AND OLAF N. ROVE. *Econ. Geol.* **25**, 36–56(1930).—Alabandite has been found in Ariz., Nev., Colo., Mont. and various foreign countries. Analyses of ore from Ariz. show about 28% Mn content. In many cases the ores have been worked as sources of Ag. Ore from the St. Anthony vein in Nev. contains 70–270 oz. of Ag per ton. Minerals found assocd. with alabandite in various regions are tabulated. A tendency is indicated toward successive deposition of silicate, sulfide and carbonate of Mn, the latest mineral being formed in part at the expense of those which preceded it. Such alterations of Mn silicate and sulfide to carbonate seem to be due to aq. solns. ALICE W. EPPERSON

The character of the ruby structure. E. ZSCHIMMER. *Sprechsaal* **63**, 832–5, 852–4(1930).—A lecture. C. H. LORIG

Preliminary note on the Lillaverke meteorite. NILS ZENZÉN. *Geol. Fören. Förh.* **52**, 366–9(1930).—A non-luminous meteorite fell May 11, 1930, at Lillaverke, Småland, Sweden. It is a stone weighing 6862 g., sp. gr. 3.1, covered with a dull black crust and looking like a chondrite. WILHELM SEGERBLOM

The computation of the probable value of ore reserves from assay results. S. J. TRUSCOTT. *Bull. Inst. Mining Met.* No. **313**, 15 pp.; No. **314**, 3–24(1930).—See *C. A.* **24**, 4737. ALDEN H. EMERY

Economic geology and allied sciences in ancient times. CORNELIO L. SAGUI. *Econ. Geol.* **25**, 65–86(1930).—The economic geologist was the leader among early Greek technicists. Prospecting was carried on by the Phoenicians. Ancient appliances for ore dressing, smelting, etc., are described and illustrated. Greek theories as to geologic phenomena did not agree, but structural geology and petrology were not unknown. ALICE W. EPPERSON

The Engels copper deposits, California. ADOLPH KNOPF AND C. A. ANDERSON. *Econ. Geol.* **25**, 14–35(1930).—The theory of igneous origin of these deposits in Plumas Co., Calif., has met with strong denial. The gangs consist of altered rocks, showing actinolitization, biotitization, and recrystn. of feldspars and quartz. Deposition of bornite and chalcopyrite lasted longer than that of magnetite and ilmenite, the sulfides occurring in fissures in the oxides only rarely. It is indicated that conditions during the forming of the ore were much like those prevailing during the deposition of contact-metamorphic Cu ores. The ore-forming conditions were pneumatolytic, the rocks characteristically looking fresh and unaltered. After the period of main deposition of the oxides and sulfides, lower-temp. (hydrothermal) alteration affected the ore bodies locally, chlorites and zeolites being formed. This juxtaposition of high-temp. minerals with low-temp. ones is a remarkable feature of these deposits. A. W. E.

The iron deposits of the Sierra de Imataca, Venezuela. GUILLERMO ZULOAGA. *Econ. Geol.* **25**, 99–101(1930).—These deposits have been considered of the same type as those of Minas Geraes, in Brazil. Z. thinks the richer Fe deposits have, in part at least, been introduced into the sediments, although there was probably some Fe present which was later redeposited. ALICE W. EPPERSON

Supergene cassiterite in tin veins. F. R. KOEBERLIN. *Econ. Geol.* **25**, 91–9 (1930).—K. discusses the "supergene" cassiterite in Bolivian tin veins and takes issue with Singewald's conclusions (*C. A.* **23**, 4168) that Bolivian cassiterite is insol. and hence there was no supergene cassiterite enrichment. Evidence is given in favor of supergene enrichment having occurred. ALICE W. EPPERSON

Mineral deposits in the Ural mountains. A. J. ZHILIN. *Keram. i Steklo* **6**, 353–6 (1930).—Z. describes investigations made to det. the possibility of using the enormous deposits of nepheline, sodalite, and other minerals of the Ural mountains for the glass and silicate industries of U. S. S. R. The chem. compn. of the minerals is given. M. V. KONDOIDY

Beryl in Manitoba. J. S. DE LURY. *Canadian Mining J.* **51**, 1015–8(1930).—An address dealing with the substantial nature of recently discovered deposits of beryl and with necessary progress in prepg. the metal from the ore and adapting it to the uses of industry before a steady sale can be developed. W. H. BOYNTON

Classification and specifications of siliceous sands. RALPH TUCK. *Econ. Geol.* **25**, 57–64(1930).—In summarizing definitions of sand, size of grain is held to be the most important factor. Sand is defined as an aggregate of unconsolidated or loosely coherent minerals or rock fragments that range in size from 1/500 to 1/8 in. Sand and sandstone are distinct materials. Lack of uniform specifications for sand for varied uses leads to much confusion. Presence or absence of clay and uniformity of grain size are the most common properties emphasized in such specifications. A detailed scheme of classifications of siliceous sands is given, including specifications for sand for the following uses: filter sand, glass, sand blast, stone sawyer's sand, grinding and polishing, for Carborundum, potter's sand, chem. and metallurgical uses, pulverizing, traction sand, sand-oil roads, stucco, roofing, concrete, sand-lime brick, asphalt pavements and flooring, cushion sand, brick mortar, stonemasonry mortar, fire or furnace sand, core sand, plaster, R.R ballast, sand-clay roads, foundry sands. Sieve tests of characteristic sands are given. ALICE W. EPPERSON

Lignin theory [of the origin of coal]. H. BODE. *Brennstoff-Chem.* **11**, 81–6(1930).—A discussion of the biol. and geological contradictions of Fischer and Schrader's lignin theory (*C. A.* **17**, 2489–92), *e. g.*, bactericidal effect of humic acids on organisms decompg cellulose and evidences of cellulosic plant structures in coal. Plates and sections are shown. F. W. JUNG

Lignin theory of the origin of coal from the biological point of view. R. LIESKE *Brennstoff-Chem.* **11**, 86–90(1930).—Reply to Bode (cf. preceding abstr.) contending recent work indicates humic acids not inhibitive to bacterial action and explaining survival of plant structures in coal. F. W. JUNG

Origin of coal according to the present position of biological investigation. R. LIESKE. *Brennstoff-Chem.* **11**, 101–5(1930); cf. preceding abstr.—A discussion of the biological stages in the formation of peat whereby first aerobic, then anaerobic, organisms decompose hydrolyzable plant constituents, the non-hydrolyzable, as lignin, becoming constituents of coal. F. W. JUNG

Origin of coal according to the present position of chemical investigation. W. FUCHS. *Brennstoff-Chem.* **11**, 106–12(1930); cf. *C. A.* **24**, 2858.—A crit. discussion of literature on plant sources of coal and chem. processes involved in transformation. Analytical data are given in support of the theory of chem. changes whereby the lignin content increases with cellulose disappearance, the source and chem. compn. of the lignin detg. the nature of the coal ultimately formed. F. W. JUNG

Asaphus limestone (Ordovician) in the drill hole of Lagedi (Eesti). K. ORVIKU *Sitzb. Naturforsch.-Ges. Univ. Tartu* **36**, No. 3–4, 180–9(1930).—The stratigraphy to a depth of about 36 m. is discussed, and chem. analyses of 8 samples are given. The compn. of the building, Echinosphaerites and Vaginatum limestone layers, resp., was: quartz 3.56, 4.61, 6.63; silicate loam 1.22, 1.40, 4.13; Fe_2O_3 0.20, 0.56, 0.44; $FeCO_3$ 0.92, 1.74, 1.02; $MnCO_3$ 0.13, 0.24, 0.07; $CaCO_3$ 84.36, 67.40, 72.31; $MgCO_3$ 8.65, 9.98, 10.73; NaCl trace, 0.21, 0.12; $Ca_3P_2O_8$ 0.53, 3.00, 1.78; FeS_2 trace, 0.05, trace; $CaSO_4$ 0.00, trace, 0.00; ignition loss 0.10, 0.15, 0.12%. The structure of the stone is discussed briefly. W. L. HILL

Organic matter, phosphorus and vanadium in the Black Sea deposits. A. D. ARKHANGELSKII AND E. V. KOPCHENOVA. *Bull. acad. sci. union rép. soviét. social* 1930,

205–15.—**Org. matter, P and V content of some Black Sea sediments in the process of deposition were detd., and the relation between the C content and other elements, particularly P and V, present was studied.** Recent deep sea deposits were found to be rich in org. matter (polybitumen, carbohydrates, gaseous hydrocarbons). In the pores and fissures of deep sea deposits (upper Euxinian) were found drops of yellowish transparent oily fluid, and also vaseline-like particles. Analyses showed that P_2O_5 is derived not from the org. matter but from the fragmentary part of the deposits. No P accumulation was found in the H_2S zone. The upper layers of this zone show higher P content derived from certain organisms; however, this is possibly decompd. into gaseous compds. and returns into the water whence it was taken up by the organisms. In the shallow ooze deposits accessible to O the conditions are more favorable to a considerable concn. of P. In some of the Fe-Mn-rich concretions 2.10–6.83% P_2O_5 was found. Analyses of deep sea deposits (gray clay, intermediate clay-lime ooze, lime ooze and black ooze) for CO_2 of carbonates, C of org. substances, and V_2O_5 show that the V content varies from 0.01 to 0.06%, and is related to the org. matter content. Evidently V compds. are extd. from the sea water by certain organisms in the process of their life activities.

Mineralogical study of certain soils of the Akhmangan plateau in Armenia. Z. N. NEMOVA. *Bull. acad. sci. union rép. soviét. social., Classe sci. phys.-math.* 1930, 157–75.—The main problem was to study the dependence of the mineralogical compn. of the soils on the underlying rocks, and to follow the changes of the minerals which took place under the influence of natural processes. N. found that the minerals in the soils of the region do not correspond to the mineralogical compn. of the underlying rocks, and therefore cannot be considered as products of their disintegration. Part of the minerals, as for instance, hypersthene, aegirite, and partly plagioclase, are probably of volcanic origin. Others, as for instance, plagioclase, glaucophane, and probably mica, were formed by the mech. action of water. Besides these 2 groups, minerals are found that were formed by sedimentary processes, *e. g.*, spheroidal calcite, chalcedony, etc.

Milling methods and costs at Presidio Mine of the American Metal Co. of Texas. VAN DYNE HOWBERT AND FRED E. GRAY. *Am. Inst. Mining Met. Eng. Tech. Publ.* No. 368, 20 pp.(1930).—150 tons of oxidized and siliceous ore are treated per day by gravity sepn. and cyaniding. An av. analysis of the ore is given as 19.7 oz. Ag, 0.02 oz. Au, 2.5% Pb and 4.87% Zn. The ore is crushed and the —10-mesh material is tabled to produce a Ag-Pb concentrate analyzing 296 oz. Ag, 0.52 oz. Au, and 43.4% Pb. The tailings are combined with the +10-mesh material to be reduced in a tube mill in circuit with a classifier. The classifier discharge, which is 97% minus 100 mesh, is cyanided.

The combined recoveries amount to 90.3% of the Ag, 97% of the Au and 34.3% of the Pb. Cost data are given for the different steps in the process. C. L. READ

Milling methods of the American Zinc Company of Tennessee, Mascot, Tennessee. C. B. STRACHAN. Bur. Mines, *Information Circ.* **6379**, 12 pp.(1930).—The Mascot concentrator treats 1900 tons of Zn ore per day by gravity concn. and flotation. In 1929 heads averaged 2.90% Zn, concentrate 60.19%, with a recovery of 90.15%. The ore consists of sphalerite, dolomite, calcite, pyrite, quartz and a small quantity of greenockite, and analyzes: $CaCO_3$ 48.11, $MgCO_3$ 35.36, SiO_2 8.73, Al_2O_3 1.04, FeO 1.33 and ZnS 5.43%. ALDEN H. EMERY

Milling practice at San Francisco Mines of Mexico, Ltd. GLENN L. ALLEN. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. **371**, 24 pp.(1930).—Description of mill and methods of concg. used in handling 1100 tons of ore per day. A typical analysis of the ore is given as Pb 8.5, Zn 10.5, Cu 0.63, Fe 4.0, insol. 35, CaO 5.5, CaF_2 14, S 7%, and Au 0.9 g. and Ag 240 g. per metric ton. The ore is reduced in a cone crusher and rod mills. It is then tabled to produce a high Pb-Ag concentrate. The tailings are then put through rod mills and classifiers, the feed to the flotation cells being 70% minus 200 mesh. Pb is floated in an alk. circuit of p_H 7.8-8.2; cresylic acid, xanthate, cyanide, $ZnSO_4$ and at times Na_2S being used. In floating the Zn, the p_H of the circuit is increased to 9.0–9.4 and creosote oil, Cu sulfate and xanthate are used. Typical analyses of the finished products are: Pb concentrate 3.91 g. Au, 1291 g. Ag, 63% Pb, 10.4% Zn and 2.8% Cu; Zn concentrate, 1.0 g. Au, 263 g. Ag, 1.8% Pb, 54.6% Zn and 1.3% Cu; tailings, 0.26 g. Au, 41 g. Ag, 0.3% Pb, 1.3% Zn and 0.1% Cu. Total metal recoveries amount to Au 77, Ag 87, Pb 97, Zn 91 and Cu 88%. C. L. READ

Trend of ore hunting in the United States. AUGUSTUS LOCKE AND PAUL BILLINGSLEY. *Eng. Mining J.* **130**, 565–6(1930).—"The new art, concerned with more remote ore, emphasizes not veins and faults only, but various marginal phenomena of mineral areas. Also, it seeks to build up such a broad and complete picture that new centers of ore deposition may be indicated by the general relationships, though direct indication by outcrop or other means be totally lacking." W. H. BOYNTON

Microscopic examination of ores. P. ERIMESCO. *Eng. Mining J.* **130**, 529 (1930).—The reflecting microscope is an indispensable aid to the geologist. A few microscopic examns. are pointed out and 4 photomicrographs shown. W. H. B.

Note on the agglomeration of fine ore from the iron mines of Rouen. EMILE FOURNIER. *Rev. ind. minérale* **235**, 435–8(1930).—The procedure of agglomeration adopted is a fritting process preceded by briquetting at high pressure. The briquetting causes an intimate contact of the minerals and they cohere at a temp. which is just below the sintering temp. By this coherence of the particles without sintering or fusion, the briquets obtained are very strong but the intermol. porosity is preserved. This product is ideal for metallurgical treatment. The briquets are pressed in a Couffinhal press which exerts simultaneous pressure on 2 faces of the briquet. The pressure is not stated. The briquets are then fired in a Cockerill tunnel furnace fired with powd. coal. A temp. of 1350° is maintained in the combustion zone when the briquets remain for 18 min. The installation at Rouen consists of 2 tunnel furnaces 70 m. long. The capacity is 220 tons per day. The briquets are bluish in color and have a strength of more than 100 kg./sq. cm. They have a porosity of 30% by vol. measured by water absorption.

The use of these briquets in the place of ore permits an increase of 20% in furnace capacity and a diminution of 17% in coke consumption. R. S. DEAN

Washing Mesabi iron ores. S. A. MAHON AND T. B. COUNSELMAN. *Eng. Mining J.* **130**, 519–21(1930).—Changes made over the original flow sheet involve: (1) the replacement of the "turbos" and tables with bowl classifiers; (2) the introduction of secondary crushing for further liberation of silica from the coarser sizes; and (3) the tendency toward the use of abrasive screening on much of the material formerly treated in the 25-ft. log washers. Several tables, and flow sheets for the original process, for bowl classification or secondary crushing, and with the Dorr washer are shown. W. H. BOYNTON

Resistance of iron ores to decrepitation and mechanical work. T. L. JOSEPH AND E. P. BARRETT. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. **372**, 15 pp.(1930).—Samples of ore were rotated in a kiln for $1^1/_2$ hr. periods. The av. decrease in av. particle size amounted to 18% when worked at room temp. and 38.1% when the temp. of the kiln was raised to 1400°F. during the $1^1/_2$ hr. period. This procedure is suggested as a method of detg. the relative amt. of potential flue dust production, as a test for ores to be screened and sintered and as a method of selecting ores for mixing in a blast furnace to obtain better gas-solid contact in the stack. Limestone was resistant to both cold and hot working. Imported Mn ore was little affected by cold working but greatly changed by hot working. C. L. READ

Combustion of blast-furnace gas. T. J. ESS. *Blast Furnace & Steel Plant* **18**, 1613–8(1930).—Blast-furnace gas is discussed with relation to characteristics, uses, cleaning and burning. C. L. READ

Carbon in the blast-furnace well. WM. MCCONNACHIE. *Blast Furnace & Steel Plant* **18**, 1629–30(1930).—From available data, it is concluded that not all the C reaching the level of the tuyères in the furnace is consumed by the O of the blast but that a portion of the O is supplied by the ore. C. L. READ

The influence of moisture due to leaking tuyères on blast-furnace conduct. C. D. ABELL. *Foundry Trade J.* **43**, 247(1930).—The moisture in the blast varies. The "winter" av. is about 0.40 lb./cu. ft. and the "summer" av. about 0.60 lb./cu. ft. It is the only source of moisture which continually dils. the reactions of the blast furnace. Moisture causes the formation of the Fe- and Mn-spinel oxides instead of the normal spinels (hercynite). Specific figures indicate losses of Fe due to excessive moisture on the assumption that equil. is obtained. Since this never proves practical, the figures simply indicate how disastrous the reactions can become, for it tends to give fusible scouring silicates, with the consequent occurrence in the hearth of pieces of apparently unreduced ore consisting mainly of Fe_2O_3 and it also accounts for the "slushy" or pasty character of the Fe cast when the furnace is running irregularly because of the presence of Fe_3O_4 in the iron. The direct results of excessive moisture are a regular-working low-temp. iron, with excess of S and oxide, combined with poor fuel economy and an increase in the rate of furnace driving with lessened production. A factor of prime importance in this respect is the greater rate of combustion of H_2 from the H_2-CO mixt. of the upper zones with attendant disorganization of the CO dissocn. reactions upon which the furnace depends for regular economic working. The extent of the possible reactions is a function of the rate of driving, and the only remedy is to introduce more fuel and extra blast, if danger is suspected from a leaking member. A. believes that 6–50 lb. water /1000 cu. ft. of blast is beneficial in most cases by producing a certain amt. of oxide in the iron. Above this figure it becomes a source of trouble. W. H. B.

Basic open-hearth slag as a valuable blast-furnace material. J. F. HORAK. *Iron Age* **126**, 980–1, 1046(1930).—Basic open-hearth slag contains about 20% SiO_2, 42% CaO, 7.5% MgO, 7.5% MnO, 1.3% Fe and 3% Al_2O_3, and the resultant increase in Mn in the pig iron due to its use is distinctly advantageous. These advantages may be summed up as follows: there is a better refining operation in the furnace resulting in cleaner, better steel, it shortens the time of the heat resulting in a greater output, and cuts the fuel consumption to the ton of steel. The amt. of basic open-hearth slag that may be charged is limited because of its P content, making its use an economic question. It should make a valuable artificial *building* and *road-making material*. W. H. B.

Another porphyry copper in the making. GEO. J. YOUNG. *Eng. Mining J.* **130**, 522–4(1930).—The developments of the Bagdad Copper property near Hillside, Ariz., its prospects and reserves and details of pilot-plant construction and operation are briefly outlined. Röntgenographic analysis of the system: lithium–silver. S. PASTORELLO. *Gazz. chim. ital.* **60**, 493–501(1930).—The present paper shows that it is possible to study a binary system by the röntgenographic method without recourse to thermal analysis. There is no previous literature on Li-Ag alloys, but Quercigh (cf. *C. A.* **5**, 638) and Mathewson (cf. *C. A.* **5**, 2786) have published data on Na-Ag alloys. The present expts. show that Li behaves very differently from Na with Ag, for it forms intermol. compds., and thus behaves more like Mg than Na (cf. S. F. Zemczuznuzy, *Z. anorg. Chem.* **49**, 405(1906); Owen and Preston, *C. A.* **21**, 855). The alloys were prepd. by heating Ag and Li together in an atm. of A in a Ni-Cr steel crucible. For alloys rich in Li it was necessary to heat around 700°, and for those with a low Li content around the m. p. of Ag. Around 500° fused Li reacts violently with Ag, especially if the latter is finely divided, with evolution of heat, indicating the formation of intermol. compds The x-ray data, which are tabulated in detail, show the formation of the *compd.* AgLi, which has a cubic lattice of the CsCl type with a = 3.225 A. U., corresponding to d. = 5.68. The existence of another compd. was also established, with the probable compn $AgLi_3$. The diagram of state shows that, with alloys contg. 80–100% Li, eutectic mixts of Li with $AgLi_3$ are present. No alteration of the Li lattice was observed, and therefore Ag is not sol. in Li in any proportion. With 52–76% Li, 2 compds. exist, while with less than 48% Li, mixts. of AgLi and Ag are present. There was no alteration in the Ag lattice, so that no solid solns. of Li in Ag are formed. C. C. DAVIS

The rearrangement of a solid metallic phase. U. DEHLINGER AND L. GRAF. *Z. Physik* **64**, 359–77(1930).—X-ray diagrams of a Cu-Au alloy (50 at. % Cu and 50 at. % Au) show that the transition of the modification consisting of cubic mixed crystals to the tetragonal system passes through a well-characterized intermediate phase of definite lattice const. and tetragonal symmetry, though the atoms are only partly ordered. The elec. cond. is found to be parallel with the structural change. Though the cubic and the tetragonal modifications are very soft, the intermediate state is exceedingly hard. The transition of the cubic phase to the tetragonal intermediate state must be due to the valency electrons. EGON BRETSCHER

Measurements of elasticity with x-rays. G. SACHS AND J. WEERTS. *Z. Physik* **64**, 344–58(1930).—The change of the lattice const. of a "Duraluminium" rod of oblong rectangular cross section on bending on the convex side is found to be proportional to the sagging. The ratio of the main dilatations is found from the spectrogram. Precision of the lattice const. is $\pm 3.10^{-4}$ A. U. EGON BRETSCHER

Acid open hearth or basic? K. R. BINKS. *Iron and Steel Ind. and British Foundryman* **4**, 53–4(1930).—The same phys. properties can be attained by both types of steel if precautions in manuf. are taken since the material in both types of open-hearth furnaces is exposed to similar influences during the melt down. C. H. LORIG

Thickness of the oxide film which produces temper color on iron. MASAWO KURODA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **14**, No. 267, 145–52(1930).—A part of the tarnished surface of a piece of mild steel, which had been colored dark blue by heating to 400°, was removed by light polishing, so as to obtain the yellowish brown color that corresponds to the temper color of lower heating. The thickness of the film, thinned by the polishing, was measured by the interference method and the value of 40.5μ obtained. Calcns. are given for the refractive index of the film. Two photographs are included, one in color of the tempered Fe with a part of its oxide film thinned by polishing, and the other, showing the interference fringes, produced between the sample and optically flat glass. DOWNS SCHAAF

The resistance of wrought-iron vessels to fluorosulfonic acid. HANS J. BRAUN. *Metallbörse* **20**, 2134(1930).—From the results obtained on testing the resistance of a wrought-iron retort to $HFSO_3$ at ordinary temp., at 130° and at 150° it is concluded

that wrought-iron vessels are sufficiently resistant to this acid. The method of testing is described. D. THUESEN

Nickel-copper-chromium cast iron (Monel cast iron, Nimol). M. WAEHLERT AND H. OSTERMANN. *Chem. Fabrik* **1930**, 377–8, 386–8, 402–4.—Losses of Nimol under acid and atm. corrosion, the analyses, structure, Brinell and losses of 15 alloys prepd. by W. and O. are discussed. J. H. MOORE

Practical application of the sulfur prints of R. Baumann. HUGO PATSCH. *Die Giesserei* **17**, 853–4(1930).—The S print method of Baumann is used for making prints of chilled and gray Fe casting surfaces contg. fine cracks. Repeatedly printing the same spots gives prints which are progressively weaker. By moistening the cracked surface with dil. H_2SO_4 and using AgBr paper which has been soaked in 5% H_2SO_4 a sharp, dark print is again obtained. J. BALOZIAN

Stability of cementite and the various forms of carbon. G. PHRAGMEN. *Jernkontorets Ann.* **114**, 431–42(1930).—A crit. review of the literature. Conclusion: The evidence indicates that cementite becomes stable at higher temps. H. C. DUUS

The heterogeneity of steel and the relationship of macrographic examination. ROGER POWELL. *Iron and Steel Ind. and Brit. Foundryman* **3**, 369–71; **4**, 29–31(1930).—Roughly classified, heterogeneity encountered in steel of miscellaneo are mech. defects, crystal growth and chem. segregation. Mech. defects are mainly pipes, roaks and seams. C. H. L.

Resistance of steels to abrasion by sand. SAMUEL J. ROSENBERG. *Bur. Standards J. Research* **5**, No. 3, 553–74(1930).—Various C steels contg. 0.08–1.29% C were tested in the normalized, annealed and hardened state. Three testing devices were used: (1) the ball mill, (2) the sand blast and (3) the Brinell machine. The ball mill proved very unsatisfactory. The sand blast was a rapid and accurate abrading medium which, however, differentiated insufficiently between steels of widely differing durability. The Brinell machine in which a stream of sand is passed between the specimen and a rotating disk gave generally reliable results. It was shown that the resistance to wear increased with the hardness. An increase in the annealing temp. resulted in a slight increase in resistance to wear, the effect being more marked in a low-C steel than in a high-C steel. The mechanism of the wear consists in the removal of small particles accompanied by severe local straining. There is no evidence that the grains are torn off in their entirety. A no. of photomicrographs, tables and diagrams are included. H. S. VAN KLOOSTER

Secondary quench of supercooled steels and stability of austenite. PIERRE CHEVENARD AND ALBERT PORTEVIN. *Compt. rend.* **191**, 523–5(1930).—A special steel of 1.5% C and 2% Cr was made austenitic by quenching from 1180° and tempered for 7 hrs at temps. varying from 100° to 700°. The microstructure, expansion, hardness, magnetism and elec. resistance were plotted as a function of the drawing temp. Below 330° and above 500° the behavior was identical with that noted previously for the steel of 1.5% C and 2% Mn (cf. *C. A.* **24**, 5697). When tempered above 350° the austenite produces on subsequent cooling martensite and at the same time becomes more and more decarburized. The hardness attains a secondary (and higher) max. between 400° and 500°. The first increase in hardness with a max. value at 330° is ascribed to the structural change austenite $\longrightarrow$ α-phase + cementite, while the second increase represents a physicochem. hardening due to martensite formation. H. S. v. K.

The mechanism of hardening steel. G. KURDYUMOV AND G. SACHS. *Z. Physik* 64, 325–43(1930); cf. *C. A.* **24**, 4746.—Austenite (γ-iron) chilled from 1100° to room temp is partially converted into a tetragonal modification, as shown by x-ray diagrams (Debye-Scherrer) from a rotating rod of the material. The dark ground of the films points to considerable irregularities in the arrangement of the atoms of the crystal lattice. Tempering leads to formation of martensite. The lattice distortion (continuous ground) diminishes with increasing temp. and time of tempering. The relative orientation of the crystals of the austenite modification, the tetragonal phase and the γ-iron has been found and the possible course of the rearrangement is discussed. EGON BRETSCHER

The nature of remanence and the losses by hysteresis. N. S. AKULOV. *Z. Physik* 64, 817–29(1930).—It is shown theoretically that single ferromagnetic crystals do not possess remanence or losses due to hysteresis. These are only found in polycryst. aggregates with internal strain. To obtain therefore a *ferromagnetic alloy* with low hysteresis losses the internal strain has to be small and the single crystals of the alloy should not possess magnetostriction. The magnetic properties of *permalloy* and *perminvar* are discussed on this basis. EGON BRETSCHER

Influence of aluminum on technical brass alloys. EDMUND R. THEWS. *Cons. Chem. Met.* **14**, 322–3, 325(1930).—Al represents one of the most useful addn. agents

when added in the correct proportions and under correct conditions. Al_2O_3 is responsible for the misgivings regarding the value of Al in brasses. Al tends to produce the valuable properties of bronzes, to increase the tensile strength, and d., increase resistance to corrosion, and in small quantities in Zn-rich brass alloys to create a freedom from Zn vapors. The production of Al-brass castings free from Al_2O_3 must be viewed from 3 angles: (1) prevention of the introduction of excessive quantities of oxide in the melt, (2) removal of the oxide from the melt previous to casting and (3) casting in a manner preventing the introduction of Al-Al_2O_3 skins into the castings. Cu should be deoxidized before the addn. of Zn and Al. While the presence of Al_2O_3 cannot be completely avoided in the bath, the addn. of a small quantity of phosphor-Cu directly previous to casting causes the oxide to float and they are easily removed. Bottom-pouring tends to minimize agitation of the bath and the introduction of dross to secure high-grade Al brass out of the brass scrap charged. A brief bibliography is appended. W. H. BOYNTON

Diffusion in cast bismuth-antimony alloys. G. MASING AND H. OVERLACH. *Wiss. Veröffentlich. Siemens Konzern.* **9**, 331–8(1930).—Phenomena leading to increased outer dimensions and formation of a cavity within are studied. F. D. ROSSINI

The temperature dependence of crystal plasticity. II. W. FAHRENHORST AND E. SCHMID. *Z. Physik* **64**, 845–55(1930).—It was previously found (*C. A.* **24**, 3147) that the slip energy is independent of temp. and stretching velocity with Cd crystals The same result was obtained with single crystals of *Zn* (slip energy 0.97 cal/g.). Diagrams relating slip and slip tension are given for the temp. from —253° to 250°. A higher temp. recrystn. disturbs these regularities. Below —83° rupture occurs by splitting along a basal face. EGON BRETSCHER

Some observations on the thickness of hot-dipped zinc coatings as actually measured with micrometer calipers. WALLACE G. IMHOFF. *Am. Metal Market* **37**, No. 226, 5, 9(Nov. 22, 1930).—The thickness of the coating was measured by micrometer readings and checked by calcg. the thickness from the known area and the total wt. of Zn deposited. The tests were made on galvanized iron water pails and results are tabulated. Measured thicknesses on different samples averaged 0.0041–0.0043 in. and the calcd. 0.0024–0.0030 in., indicating an alloy bond of 0.0013–0.0017 in. W. H. B.

The destructive action of molten zinc, at and above zincing (galvanizing) temperatures, upon metals and alloys. XI. The action upon non-metallic materials—general summary. WALLACE G. IMHOFF. *Am. Metal Market* **37**, No. 203, 11 (Oct. 21, 1930); cf. *C. A.* **24**, 5705.—A thermometer casing was coated with vitreous enamel and tested in the galvanizing bath. From a com. standpoint vitreous enamels gave the highest resistance to the action of molten Zn under galvanizing conditions. A complete summary is made in 23 subdivisions and it is concluded that nothing has so far been found that entirely withstands the corrosive action of molten Zn at galvanizing temps. W. H. BOYNTON

Metal corrosion by fuel. S. P. USPENSKII AND N. I. LADUIZHNIKOVA. *Neftyanoe Khozyaistvo* **19**, 264–77(1930).—Metal plates were cut 4 × 4 cm., cleaned with emery paper, washed with petr. ether, dried with filtering paper and weighed. One plate of each metal was then placed in 200 cc. beakers filled with Krasnodar aviation gasoline, Grozny aviation gasoline, Grozny II grade gasoline, motor benzene, acetone, CS_2, refined C_2H_5OH, refined CH_3OH, com. C_2H_5OH and com. CH_3OH. Another series of plates was half immersed, and a third series of plates was placed above the liquids. All beakers were hermetically sealed and left for a few months. The ppts., if

any, as well as the liquids were analyzed for metals. Only the Grozny aviation gasoline did not have any corrosive action. The effect of the other fuels is given in the table: Loss in mg. per sq. cm.

	In liquid				In vapors				Duration
	Pb	Cu	Brass	Fe	Pb	Cu	Brass	Fe	months

A. A. BOEHTLINGK

How to prevent rust. PIETRO CHIARIA. *Giorn. farm. chim.* **79**, 316, 319–21 (1930).—A review of the ordinary methods is given. G. SCHWOCH

Electric welding in carbonization plants and gas works. W. KÜRSCHNER. *Brennstoff-Chem.* **10**, 468–9(1929).—Advantages of elec. welding over riveting for these applications are discussed. F. W. JUNG

Corrosion of riveting and welding in combustion and chemical practice. O. GROSS. *Brennstoff-Chem.* **11**, 133–4(1930). F. W. JUNG

Strengthening the soldering of tramcar wires. A general study of solders. J. NAVARRO ALCÁCER. *Anales soc. expañ. fís. quím.* **28**, 1050–4(1930).—Photomicrographs are shown of the original trolley wire, after soldering to the support, and after rapid chilling after soldering. The solder used was a low-melting Cu-Zn-Ag mixt. Low heat and rapid quenching improve the wearing properties of the wire. E. M. S.

Beryl in Manitoba (DE LURY) **8**. Apparatus for separating materials of different specific gravities such as minerals by the action of vibration and air currents (U. S. pat. 1,782,391–2) **1**. Bleaching and other treatments of fabrics (Brit. pat. 332,718) **25**. Apparatus suitable for various chemical or evaporating operations (U. S. pat. 1,783,726) **1**. Electrically heated apparatus for roasting ores, etc. (U. S. pat. 1,782,946) **4**.

Froth flotation ore separation. GEORGE H. WIGTON. U. S. 1,783,206, Dec. 2. A pulp of oxidized ore such as ore from the Tintic district, Utah, is subjected to a flotation operation in the presence of the reaction product of an alc. soln. of α-naphthylamine or other amino compd. and P_4S_{10}. U. S. 1,783,207 specifies the use of the reaction product of an O-free aromatic amino compd. such as α-naphthylamine and *o*-toluidine and P_4S_{10}.

Method and apparatus for gravity separation of ores or other materials with an agitated mixture of liquid and solid of intermediate specific gravity. THOMAS M. CHANCE. U. S. reissue 17,873, Nov. 18. Reissue of original patent No. 1,685,521 (*C. A.* **22**, 4679).

Froth flotation mineral concentration. LOCKWOOD W. FERRIS. U. S. 1,784,280, Dec. 9. Ores such as those contg. Cu silicate minerals are subjected to heat alone without addn. of reagents to decompose the Cu silicates, and the heated material is then subjected to froth flotation.

Concentrating ores, etc. HARALD SKAPPEL. Ger. 504,487, Feb. 26, 1924. See Brit. 211,895 (*C. A.* **18**, 2122).

Ore-concentrating apparatus. CLAUDE N. BIELENBERG. U. S. 1,781,971, Nov. 18. Structural features.

Ore-concentrating table. FREDERICK C. DYER. U. S. 1,781,810, Nov. 18. Structural features.

Apparatus for leaching and washing ores by use of gas. ALBERT B. STEVENS. U. S. 1,783,591, Dec. 2. Structural features.

Apparatus suitable for agglomerating and roasting minerals. ALEXANDRE DE SAMSONOW (to Soc. pour l'enrichissement et l'agglomeration des minerals, Soc. Anon.). U. S. 1,784,658, Dec. 9. Structural features.

Apparatus for wet classification of solids such as low-grade iron ore. HARRY W. NEWTON (to Dorr Co.). U. S. 1,784,246, Dec. 9. Structural features.

Preparing copper ores for leaching. CARL E. CARSTENS (to Anaconda Copper

Mining Co.). U. S. 1,782,841, Nov. 25. About 4 to 5% by wt. of moisture is added to crushed oxide ores of Cu contg. fines, prior to introduction into a leaching vat, in order to prevent segregation of fines.

Conveyer tube (with insulation and water jacket) for use with heated ore, etc. JOHN W. HORNSEY (to Granular Iron Co.). U. S. 1,782,423, Nov. 25. Structural features.

Recovering volatile metals from slags, etc. ULYSSES A. GARRED (to Anaconda Copper Mining Co.). U. S. 1,782,418, Nov. 25. See Fr. 638,638 (*C. A.* **23**, 366).

Treating barytes. CASPAR P. DE LORE and BRACK B. MCHAN (McHan to De Lore). U. S. 1,783,778, Dec. 2. In the treatment of acid bleached barytes ore, the ore is washed with a wash water contg. a sufficient quantity of a reducing agent such as sulfurous acid to prevent oxidation of the metallic salt present with the barytes and to convert insol. salts into sol. form so that the product may be washed free from impurities.

Separating cobalt and iron from solutions such as those obtained by lixiviating roasted pyrites. NILS E. LENANDER (to Orkla Grube-Aktiebolag). U. S. 1,783,046, Nov. 25. Ferrous Fe in the soln. is oxidized with an alkali metal chlorate, the ferric Fe is pptd., and Co is then recovered from the soln.

Metallurgical plant. GRANULAR IRON CO. Ger. 506,340, July 1, 1927. A plant is described for the manuf. of Fe and other metals by reduction of their oxides without fusion. The plant comprises a no. of rotary drums in which the ore is successively preheated, reduced and cooled.

Method and apparatus for fusing pulverulent masses, especially blast-furnace dust. ADRIEN DAWANS. Ger. 506,350, Aug. 5, 1927.

Apparatus for continuous indication and recording of the temperature of molten iron at a pouring spout. HARRY W. DIETERT (to U. S. Radiator Corp.). U. S. 1,784,420, Dec. 9.

Purifying pig iron. KONRAD HOFMANN (to Fried. Krupp A.-G.). U. S. 1,782,923, Nov. 25. See Brit. 312,361 (*C. A.* **24**, 819).

Preparing foundry molds by use of impacts and pressure. M. GRINDAL. Brit. 332,712, June 3, 1929. App. is described.

Mold for casting metals. WM. G. GOODWIN. U. S. 1,783,285, Dec. 2. Structural features.

Casting and heating ingots. C. A. PARSONS. Brit. 332,654, May 3, 1929. Heat is supplied to the top surface of the ingot principally toward the periphery (suitably by hot gases or a high-frequency induction coil). App. is described.

Iron casting composition. RUDOLF SCHENCK. Ger. 506,352, Sept. 24, 1927. A compn. suitable for casting into machine parts, etc., is prepd. by fusing Fe_2O_3 with Fe poor in C so that the mass contains 21–25% of O. Addns. of other oxides, *e. g.*, MgO, MnO or CaO, may be made.

Apparatus for casting zinc slabs, etc. DANIEL M. GRAY and JOHN J. WILLIAMS (to Hazel-Atlas Glass Co.). U. S. 1,782,920, Nov. 25. A vacuum pump serves to degasify and transfer the molten metal.

Recovery of tin from residues of tin-plate manufacture. JEHAN LALEY (to Les petits fils de Francois de Wendel & Cie). U. S. 1,784,490, Dec. 9. See Fr. 661,818 (*C. A.* **24**, 1072).

Filtering and dust collecting apparatus suitable for treating smelter gases. INGENUIN HECHENBLEIKNER (to Chemical Construction Corp.). U. S. 1,782,823, Nov. 25 Structural features of an app. comprising a holder with internal transverse grid structure, the holder being substantially filled with a granular mass such as sand fed in cyclic manner.

Furnace with two hearth units, suitable for volatilizing roasting of ores, etc. FREDERICK L. PRESTON. U. S. 1,784,109, Dec. 9. A hood is provided shiftable endwise of the furnace, for use with either unit of the hearth, and a common heating chamber extends beneath both hearths.

Furnace for the production of pure tin direct from the ore. CAYZER TIN SMELTING CO. (Pty), LTD. Ger. 505,722, June 17, 1928. The powd. Sn ore mixed with C is placed on a porous hearth made of spongy Fe obtained by reducing Fe ore with C in the furnace just prior to the introduction of the Sn ore.

Blast furnace. JAMES P. DOVEL (to G. P. Dovel). U. S. 1,783,416, Dec. 2.

Rotary-hearth furnace suitable for heat treatments. ALAN D. DAUCH (to George J. Hagan Co.). U. S. 1,782,956, Nov. 25. Structural features.

Rotary case-hardening furnace. ERNST GOERIG. U. S. 1,784,427, Dec. 9. Structural features.

Protecting inside walls of metallurgical furnaces with steam. HENRY F. EASTER (to American Smelting & Refining Co.). U. S. 1,783,284, Dec. 2. The inside walls of furnaces are protected from the scorifying action of the contents of the furnace by providing a coating of steam on the inside wall without substantially changing the normal operating atm. throughout the body of the furnace. A furnace construction is described.

Furnace for annealing elongated metal blanks, tubes, etc. GRANT B. SHIPLEY and HENRY ALINDER (to International Nickel Co.). U. S. 1,782,481, Nov. 25.

Heat treatment suitable for annealing brass, iron, steel, etc. JOHN R. CAIN (to The Richardson Co.). U. S. 1,784,221, Dec. 9. In a liquid annealing medium, such as Pb and superposed hydrocarbon oil, a temp. gradient is maintained ranging from a temp. at least as high as that necessary to effect the desired heat treatment to a temp. at least as low as will permit withdrawal of a heat treated article to the air without danger of formation of scale or oxide on the article; an article under treatment is advanced from a cooler portion of the liquid medium to a heat treating zone where it is kept for the desired heat treatment, and then withdrawn through a cooler portion of the liquid medium. App. is described.

Furnace and endless conveyer for heat-treating articles such as universal joint parts. HORACE L. WAISNER (to Mechanics Universal Joint Co.). U. S. 1,782,451, Nov. 25.

Apparatus for conveying articles through heat-treating furnaces. GEORGE F. BEACH (to Ryan, Scully & Co.). U. S. 1,782,335, Nov. 18. Structural features.

Quenching tank suitable for use in cooling metal tools after heat treatment. HAROLD W. FLETCHER (to Hughes Tool Co.). U. S. 1,784,095, Dec. 9.

Electric immersion heaters in vats of metal-pickling solution. WM. C. SIEFERT and GEORGE W. PAWEL (to International Nickel Co.). U. S. 1,782,482, Nov. 25. Structural features.

Etching precious metals. JAMES C. MCFARLAND (to Wadsworth Watch Case Co.). U. S. 1,783,663, Dec. 2. A Cr plating is applied to serve as a resist for the etching fluid for the precious metal, and the exposed surface of the precious metal is etched while the plating design serves as a resist; the Cr plating is then removed. Cf. *C. A.* **24**, 2104.

Local case-hardening of iron and steel. FRANZ KRUŠEK. Austrian 119,023, Apr. 15, 1930. A paste to be applied to the parts that are not to be hardened comprises pipe clay, glass meal and asbestos meal bound with an aq. soln. of crude sugar.

Steel. FRANZIE ANTOINETTE DE SILVA and CHARLES GEO. CARLISLE. Ger. 506,351, Aug. 18, 1927. See Brit. 290,442 (*C. A.* **23**, 812).

Rolling mill for rolling metals. WILLIAM F. DETWILER (to Allegheny Steel Co.). U. S. 1,781,809, Nov. 18.

Special alloy rolling-mill guides. MARVINE GORHAM (to Michigan Steel Casting Co.) U. S. 1,783,148, Nov. 25. Portions of guides subjected to the wear of highly heated bars and billets are formed of an alloy of Fe together with Ni 32–38, Cr 13–17, C 0.35–0.65, Si 0.9–1.4 and Mn 0.85–0.95%.

White alloy suitable for general use as a substitute for nickel-plated brass. CHARLES PHILIPPOSSIAN. U. S. 1,783,139, Nov. 25. An alloy which is readily worked has the approx. compn. Cu 66.554, Ni 18.2, Zn 14.5, Mg 0.19, Al 0.19, Cd 0.098, Si 0.078 and Mn 0.19%. Cf. *C. A.* **24**, 583.

White metal. OSKAR GRÜNBAUM. Austrian 118,864, July 15, 1928. Addn. to 109,161 The alloy described in Austrian 109,161 (*C. A.* **22**, 4452) is modified by replacing part of the Zn by Cd.

White metal. N. V. TINKOPER HANDELMAATSCHAPPIJ. Ger. 506,082, Nov. 11, 1926 Mo 0.1–3, Sn 3–16, Ni 0.5–15, Fe 0.1–1 and Cu 96.3–65%.

Aluminum alloy. HORACE C. HALL and TENNYSON F. BRADBURY (to Rolls-Royce, Ltd.). U. S. 1,782,300, Nov. 18. See Brit. 323,353 (*C. A.* **24**, 2977).

Special alloy poppet valves. WARREN NOBLE. U. S. 1,784,640, Dec. 9. Heads of poppet valves for internal-combustion engines are made of a binary alloy of Ag 90% and a hardening agent such as Mg 10% to give high heat cond. and wear-resisting characteristics.

Refining alloys of magnesium or alkaline earth metals electrolytically. ALFRED CLAUDE JESSUP. Ger. 504,508, Sept. 12, 1926. A layer of readily fusible compd., such as chlorides of the metals, is placed on the layer of fused metal floating on the surface of the electrolyte, to protect it against the air.

Improving the resistance to corrosion of magnesium and its alloys. ADOLF BECK and GUSTAV SIEBEL (to I. G. Farbenind. A.-G.). U. S. 1,783,770, Dec. 2. Materials

contg. at least 8% Mg are treated with a boiling aq. soln. of dichromates for about at least an hr.

Device for the accurate preparation of amalgams. RICHARD LESSMANN. Ger. 504,551, Mar. 15, 1929.

Coating articles of ferrous metal. FREDERICK M. BECKET (to Electro Metallurgical Co.). U. S. 1,784,570, Dec. 9. Articles are heated in contact with a mixt. contg. a fluosilicate such as that of Na and an alloy of Fe, Cr and Si until cementation is effected.

Coating zinc and cadmium. ALADAR PACZ. U. S. 1,784,106, Dec. 9. For producing coatings on Zn and Cd, which are of preservative and decorative character, a non-alk. dipping soln. is used contg. a sol. molybdate such as NH_4 molybdate and a second sol. salt such as $(NH_4)_2SO_4$ which is non-alk. and does not ppt. Mo.

Apparatus for coating wire with copper, etc., after treatment with acid. CHARLES D. JOHNSON (to Johnson Steel & Wire Co.). U. S. 1,783,429, Dec. 2. An app. is described for treating wire with an acid bath, a coating bath and a washing bath and also with an air jet.

Detecting faults in articles such as rails, cables, wires or tubes by apparatus comprising electric magnetizing coils operating on alternating current. HELMUT CHAPUZEAU AND OTTO EMERSLEBEN (to Neufeldt & Kuhnke Betriebsges. m. b. H.). U. S. 1,782,462, Nov. 25.

Thick-walled electrically welded metal pressure vessels. RICHARD STRESAU (to A. O. Smith Corp.). U. S. 1,784,080, Dec. 9. Various details of annealing and mech. treatment and final heat treatment to relieve stresses are described, adapted to the manuf. of app. such as that for use in *oil cracking*.

Electric welding of metals. BORIS S. ROBINOFF, SUMNER E. PAINE and WRIGNOL E. QUILLEN (to National Tube Co.) U. S. 1,782,316, Nov. 18. A groove is formed along the seam to be welded, flux is placed in the groove, a metal electrode is moved along the groove and an arc is drawn causing the flux to melt and causing molten metal from the electrode to be deposited through the melted flux. App. is described.

Electric arc-welding apparatus. FULTON LANE and HARRY J. MORGAN (to P. L. and M. Co.). U. S. 1,784,015, Dec. 9. Mech. and elec. features.

Rod for use in arc welding or cutting. J. B. GREEN (to Franklin M. Warden). U. S. 1,783,013, Nov. 25. A filler material such as a metal rod is coated with compds. of W and U oxides, such as a product formed from U oxide and Na tungstate. Cf. *C. A.* **24**, 333.

Soldering flux. HARRY C. MOUGEY (to General Motors Research Corp.). U. S. 1,783,925, Dec. 2. $ZnCl_2$ and water are used together with a water-sol. oil solvent such as di-, tri- and tetra-ethylene glycol, Et and Bu carbitol, the mono-acetates of ethylene and diethylene glycol and of the methyl and ethyl ethers of ethylene glycol, Et lactate, Et oxybutyrate and di-acetone alc.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

The history of stereochemistry; a memorial on the death of J. A. Le Bel. E. WEDEKIND. *Z. angew. Chem.* **43**, 985–6(1930). E. H.

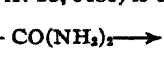
Bivalency of carbon. IV. Halogen displacements from *sym*-tetrabromo- and -chloroethane and tribromo- and -chloroethylene. ALLAN M. WARD. *J. Chem. Soc.* **1930**, 2143–8; cf. *C. A.* **24**, 2749.—No Br displacement takes place from $(CHBr_2)_2$ in EtOH at 15° and 25° but 1 Br atom is displaced instantaneously at these temps. in the presence of NaOH or EtONa, CBr_2:CHBr being formed. The same velocity coeff. should therefore be obtained by using $(CHBr_2)_2$ and CBr_2:CHBr, which was the case, the reaction being bimol. The velocity coeffs. for NaOH and EtONa are the same; the temp. coeff. for the range 15–25° is about 4.5. $(CHCl_2)_2$ behaves similarly, 1 Cl atom being displaced instantly from $(CHCl_2)_2$ by NaOH or EtONa but further displacement at 15–25° was very slow and kinetic expts. were therefore not carried out. C. J. WEST

Isoprene sulfone. ERNEST EIGENBERGER. *J. prakt. Chem.* **127**, 307–36(1930).—prene (10 g.) and 100 cc. Et_2O, satd. with SO_2 and heated 5 hrs. in the H_2O bath, give of *isoprene sulfone (2-methyl-2-butene, sulfone < 1,4 >)* (I), m. 63–3.5°, decomps. 5°. I is stable toward 0.5 *N* NaOH during 15 min. boiling. In neutral or nearly neutral media, titration with $KMnO_4$ proceeds in such a way that nearly 2

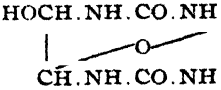
mols. O are consumed per mol. sulfone before the oxidation is noticeably slowed up, with the formation of a monobasic acid; a by-product of the reaction is an oxidative degradation with the formation of H_2SO_4. Details of the oxidation under various conditions are reported; a product of the oxidation is the *disulfone*, $C_{10}H_{20}O_8S_2$, m. 130°. I (10 g.) and 13 g. Br in 20 cc. CCl_4 give 19 g. of the *dibromide* (II), m. 127°. Boiling the latter with H_2O gives the bromohydrin (*3-bromo-2-methylbutan-2-ol sulfone* < *1,4* >), m. 67–8°; $BaCO_3$ splits off HBr and SO_2; MeONa in MeOH appears to give a di-Me ether; with excess 5.5 *N* MeONa in MeOH there results *3-methoxy-2-methyl-2-butene sulfone* < *1,4* >, b_{13} 1.0°, m. 44–5°; Br in $CHCl_3$ gives *2,3-dibromo-3-methoxy-2-methylbutane sulfone* < *1,4* >, m. 151–2°; sapon. of the enol ether gives *2-methylbutan-3-one sulfone* < *1,4* >, m. 180°; *phenylhydrazone*, m. 167°. The ketone is easily saponifiable by *N* alkali, giving *4-hydroxy-2-methylbutan-3-one-1-sulfinic acid*, giving with $PhNHNH_2$ a *$PhNHNH_2$ salt* of the *osazone*, decomps. without melting. II and MeOH-NaOH give a thick oil, which polymerizes to a yellow *2-methyl-2,3-butadiene sulfone* < , > , $(C_5H_6(OH)_2O_2S)_x$, which does not react with Br. Oxidation with $KMnO_4$, using 4.2 atoms O per mol., gives a product analyzing approx. $C_{3.5}H_7O_{6.5}S$; with 2.5 atoms O there results a product which with $PhNHNHH_2$ gives a *$PhNHNH_2$ salt*, $C_{28}H_{26}O_3N_6S$, which gives with dil. alkali the *K salt* of the *osazone*, $C_{17}H_{19}O_3N_4K$; hot HCl and neutralization gives the *K salt* of a *monohydrazone*, $C_{11}H_{13}O_4N_2SK$; the *semicarbazone*, $C_6H_{10}O_5N_3SK$, was not obtained pure. With 5.7 atoms O, there results a compd. which yields a *phenylhydrazine salt* of an *osazone*, $C_{21}H_{24}O_3N_6S$. C. J. West

Decomposition of the acids of peanut oil with the use of a new principle in fractional distillation. Ernst Jantzen and Carl Tiedcke. *J. prakt. Chem.* **127**, 277–91 (1930).—A column is described for fractional distn. in high vacuum and a device is developed for measuring the m. p. of the distillate during the distn. The working of this app. is illustrated by the sepn. of the Me esters of palmitic and stearic acids. The high-melting acids of peanut oil are sepd. by means of this app into eicosanic, docosanic and tetracosanic acids Thus the presence of the 1st two acids is confirmed and the presence of tetracosanic acid is made certain for the 1st time. No evidence is found for the presence of acids of odd C atoms or branched chains. It is therefore improbable that isobehenic or lignoceric acids are present in peanut oil. The following m. ps. are reported for synthetic products contg. C_{18}, C_{20}, C_{22} and C_{24}: Acid, 69.2°, 74.8–75.0°, 79.8–80°, 83.4–84.0°. Ph ester, 52°, 58.5°, 62.8–3.2°, ——. Alc., 59°, 65–5.2°, 70.8°, ——. Iodide, 34°, 41.5–2°, 47.8–8.0°, ——. C. J. West

Degradation of ethylenebissulfonylacetic acid in alkaline solution. Sulfinoacetic acid and hydroxyethylsulfonylacetic acid. J. A. Reuterskiöld. *J. prakt. Chem.* **127**, 269–76(1930).—$(CH_2SO_2CH_2CO_2H)_2$ in 140 cc. H_2O, treated with a little more than 1.5 equivs. of 4 *N* NaOH and allowed to stand 24 hrs., gives a mixt. of *sulfinoacetic acid* (I) and *hydroxyethylsulfonylacetic acid* (II). I is pptd. from the neutralized soln. by $SrCl_2$ as the *Sr salt*, crystals with 0.5 mol. H_2O; distn. of a soln. of the salt with H_2SO_4 gives AcOH; oxidation with H_2O_2 gives $HO_3SCH_2CO_2H$; the *Ag salt* of I was also prepd. In neutral and alk. soln. I is stable, even after short warming; in acid soln. at low temps., SO_2 is split off at once; even at —20° in Et_2O SO_2 is split off, giving AcOH. At —70° a rather stable soln. of I may be prepd. in Me_2CO. From the mother liquor, II is sepd. as the *Pb salt*, which crystallizes with 1 mol. H_2O. The free II m. 87–9°. Bromination of a soln. of II gives *dibromomethylsulfonylethyl ether*, m. 126.5–7.5°. C. J. West



Conductivity measurements of the comparative rates of hydrolysis of lactones derived from simple sugars. Sydney R. Carter, Walter N. Haworth and Robert A. Robinson. *J. Chem. Soc.* **1930**, 2125–33.—Data are given for the cond. of various lactones over a period of days (until a const. value is obtained); the values obtained for the equil. % agree well with the values previously obtained by polarimetric measurements. The lactones studied were: tetramethyl-γ- and -δ-mannonolactones, tetramethyl-γ- and -δ-gluconolactones, tetramethyl-γ- and -δ-galactonolactones, trimethyl-δ-rhamnonolactone, trimethyl-γ- and -δ-arabonolactones, trimethyl-γ- and -δ-xylonolactones, mannono-γ- and -δ-lactones, glucono-γ- and -δ-lactones and galactono-γ-lactone. The relative rates of hydrolysis of the 2 series are also shown as curves. The lowest rate found among the δ-lactones is several times as great as the highest rate among the γ-series. C. J. West



Some salts with *p*-, *o*- and *m*-quinoid structure. VII. R. Ciusa and L. Musajo. *Gazz. chim. ital.* **60**, 486–92(1930).—From 3 nitrophenylhydrazones of $AcCO_2H$ which were described in an earlier paper (*C. A.* **18**, 2138) numerous mono-metallic salts were prepd. with the object of ascertaining whether any of the salts might have a complex structure. Such a structure might indicate the existence of rings with more than 6 atoms, with participation of secondary valences in the closing of the ring. This struc-

ture is probably characteristic of salts of *p*-nitrophenylnitromethane (cf. Hantzsch, *Ber.* 40, 1533). The existence of internal complex salts is also probable in the case of alk. salts of derivs. of benzoyl- and acetylmethylphenylhydrazine, for while the salts of PhNMeN:C(OH)Ph are colorless, those of methyl(or ethyl)benzoyl-*p*-nitrophenylhydrazine are red (cf. *C. A.* 21, 1251). The *o*-nitrophenylhydrazone and its Na and K salts have already been described (Ciusa and Rastelli, *C. A.* 17, 1449). Prepd. by addn. of aq. $AcCO_2H$ (4 g.) to warm *m*-$O_2NC_6H_4NHNH_2$ in dil. AcOH, cooling and recrystn. of the ppt. from EtOH, *m-nitrophenylhydrazone* is yellow and m. 226°. The *p*-nitrophenylhydrazone and its Na and K salts have already been described (cf. Fischer, *Ann.* 253, 64; Hyde, *Ber.* 32, 1215; Ciusa and Rastelli, *loc. cit.*). Of the other salts described in the present paper, some were prepd. by the action of the hot hydrazone on aq. solns. or suspensions of the carbonate. On cooling the filtered soln, the salts crystd. Others were prepd. by double decompn. of alk. salt solns. of the hydrazones and solns. of the metallic salts. The NH_4 salts were prepd. by passing dry NH_3 into suspensions of the phenylhydrazones in abs. EtOH, and adding to the alc. soln. twice the vol. of Et_2O, which caused crystn. of the NH_4 salts. All the salts correspond to the general formula $Me(MO_2C)C:NNHC_6H_4NO_2$. The following data give the color (and in some cases other information) of the particular salts of the *o*-nitro-, *m*-nitro- and *p*-nitrophenylhydrazone of $AcCO_2H$, resp.: *NH_4*, brilliant yellow, yellow (m. 210–11°), yellow; *Li*, yellow, yellow, yellow; *Na*, already described (*loc. cit.*), yellow, already described (*loc. cit.*); *K*, already described (*loc. cit.*), lustrous (from AmOH), already described (*loc. cit.*); *Mg*, yellow (from water), yellow (from water), yellow (from water); *Ca*, yellow, yellow, yellow (from water); *Sr*, yellow, yellow (from water), yellow (from water) *Ba*, yellow, yellow (from water or EtOH), (from water); *Ni*, green-yellow, green-yellow (from water), green-yellow; *Co*, brick-red, intense yellow (from water), brick-yellow; *Cr*, golden yellow, yellow (from water), orange-yellow; *Mn*, yellow (from water), yellow (from water), yellow; *Al*, light yellow (from water), light yellow (from water), yellow; *Fe*, ——, the ferrous and ferric salts decomp., ——; *Hg*, yellow, yellow (from dil. cold solns.), decomps. easily; *Ag*, yellow (blackens in light), yellow (blackens in light), brick-red (lighter flesh-red when dry); *Cu*, yellow, green-yellow, green-yellow. In general the salts are yellow even where the metals usually form salts of other colors. The properties, particularly the differences in color of the *o*-, *m*- and *p*-derivs., of the Co salt of the *o*-nitrophenylhydrazone deriv. and the Ag salt of the *p*-nitrophenylhydrazone deriv. suggest a complex structure. The absence of any indication of complex salt formation among the *m*-derivs. is accounted for by the fact that the rule of Angeli is true only of *o*- and *p*- derivs. C. C. Davis

Derivatives of *dl*-asparagine. S. Berlingozzi and G. Carobbi. *Gazz. chim. ital* 60, 573–82(1930); cf. B., *C. A.* 23, 1620.—In the previous expts. there were obtained from the 2 rotatory asparagines 2 different series of acyl derivs. of the compn. $H_2NCOCH_2CH(CO_2H)NHCOR$, which are enantiomorphic. With these, attempts were made to obtain the *dl*-forms by direct union of the antipodes. Such tests gave positive results in 2 cases, while in the 3rd case the results were uncertain. With the object of clearing this uncertainty, the expts. were repeated under better conditions and were also extended to other acyl derivs. of the rotatory asparagines. Besides this, the d. and other consts. and the crystallographic characteristics of the compds. were studied. The results of the expts. confirm in general the formation of the *dl*-forms in all cases, so that in spite of the rotatory asparagines showing no tendency to form *dl*-forms under ordinary exptl. conditions, their acyl derivs. behave quite differently. *Expt.*—An improved *method for the prepn. of dl-$ClCH_2CONHCH(CO_2H)CH_2CONH_2$*, which gives a higher yield than in the previous work, involves dissolving each of the 2 antipodes (2 g.) in water (20 cc.) at approx. 30°, mixing the solns., evapg. very slowly at 30°, and recrystg. the residue from water, which yields 3.5 g. of *hydrated dl-chloroacetylasparagine*, $ClCH_2CONHCH(CO_2H)CH_2CONH_2 . H_2O$, m. 105°, loses its H_2O of crystn. at 60°, d_{15} 1.560; its aq. soln. is optically inactive; its crystals are triclinic (pinacoidal class), *a*:*b*:*c* = 0.9068:1:0.8617, mol. vol. 145.23. The *d*- and *l*-chloroacetylasparagines both m. 150°, d_{15} 1.538; their crystals are monoclinic (sphenoidic class), *a*:*b*:*c* = 0.7876:1:0.4281, mol. vol. 135.59. *dl*-$BzNHCH(CO_2H)CH_2CONH_2$, prepd. by the method previously described, m. 184°, d_{15} 1.433; its aq. solns. (Na salt) are optically inactive, its crystals are monoclinic (prismatic class), *a*:*b*:*c* = 0.8865:1:0.5929, mol. vol. 164.76. The *d*- and *l*-benzoylasparagines m. 189°, d_{15} 1.474, mol. vol. 160.18; their aq. solns. have $[\alpha]_D^{20}$ 36.4°. No success was had in obtaining crystals of the *d*- and *l*-forms large enough for thorough crystallographic analysis. *d*-Asparagine in *N* NaOH (calcd. quantity), agitated with $PhSO_2Cl$ (calcd. quantity) in Et_2O (added in small portions alternated with corresponding quantities of *N* NaOH), and acidified,

ppts. *d-benzenesulfonylasparagine*, $PhSO_2NHCH(CO_2H)CH_2CONH_2$, m. 163°, d_{18} 1.434; its crystals are monoclinic (sphenoidic class), $a:b:c$ = 0.7557:1:0.7105; its *Na salt* in water is optically inactive. In the same way from *l*-asparagine was prepd. *l-benzenesulfonylasparagine*, m. 163°, d_{18} 1.434; its crystals are monoclinic (sphenoidic class), $a:b:c$ = 0.7557:1:0.7105; its *Na salt* in water is optically inactive. An aq. soln. of the Na salts of the *d*- and *l*-forms (equimol. quantities) ppt. after acidification *dl-benzenesulfonylasparagine*, m. 172°, d_{18} 1.559; its crystals are monoclinic prisms but were too minute to be analyzed crystallographically, mol. vol. 174.59. C. C. Davis

Action of glyoxal on urea; new methods of formation of hydantoin. H. Pauly and Heinr. Sauter. *Ber.* **63B**, 2063–9(1930).—von Lippmann had observed that the juice of the pale sprouts growing from beets in moist warm weather contains hydantoin (I); if Klein's view that the urea circulating in the juice of plants combines with the aldehydes formed in the CO_2 assimilation (*C. A.* **23**, 5486) is correct, the formation of I might be represented by the scheme $(CHO)_2 + CO(NH_2)_2 \longrightarrow$  (II) $\longrightarrow$ I.

This reaction can be readily carried out *in vitro* and explains why $(CHO)_2$ has not hitherto been detected in plant juices, for the condensation to II occurs in H_2O without the aid of reagents or heat and is apparently irreversible. The dehydration of the monourein II to I is easily effected with hot HCl. II is identical with the product obtained in small amt. by Franchimont and Klobbie by the decompn. of dinitroglyoxaldiurein. In the presence of HCl (*i. e.*, conditions under which the known diurein (III) is formed), there is obtained a *compd.* $C_6H_{10}O_6N_4.3H_2O$ (IV), to which is assigned the structure  . Like II, it takes up 2, and only 2, atoms Na from 10% aq. NaOH, and whereas I can condense with another mol. of urea to form III, IV cannot. Repetition of the work of Behrend, Meyer and Rusche (*Ann.* 339, 5 (1905)) has shown that their supposed compds. $C_{11}H_{18}N_8O_{10}$ and $C_{10}H_{16}N_{12}O_{10}$ were very impure mixts. of IV with III or I. *2-Oxo-4,5-dihydroxyimidazole tetrahydride* (II) (21 g. from 50 cc. of a soln. of 18.75 g. $(CHO)_2$ with 24 g. urea concd. *in vacuo* to a thin sirup and stirred with MeOH), m. 146°; *di-Na salt*. IV, prepd. by cautiously mixing 100 cc. of 38% $(CHO)_2$ soln. with 22.5 g. urea in 50 g. HCl (d. 1.14) and sepg. from the somewhat less basic III with 27% HCl, chalky powder, m. 95–7° (when anhyd., it carbonizes without melting); *di-Na salt*. With boiling HCl, both II and IV give I. *Glyoxalbis(carbethoxyimide)*, from $(CHO)_2$ or its sulfate with 2 mols. urethan in HCl (d. 1.08) on the H_2O bath, microcryst. powder with no m. p. *Glyoxaldithiourein*, from $(CHO)_2$ or its sulfate with 2 mols. $CS(NH_2)_2$ in dil. HCl, tablets with no m. p. C. A. R.

New synthesis of creatine and alacreatine. Harold King. *J. Chem. Soc.* **1930**, 2374–7.—$H_2NCH_2CO_2H$ (7.5 g.) in 100 cc. *N* KOH and 21.7 g. $HN:C(NH_2)SMe.HI$, slowly evapd., give 10.2 g. glycocyamine, $H_2NC(:NH)NHCH_2CO_2H$; heating with concd. HCl 6.5 hrs. at 150° gives 74% of glycocyamidine-HCl, m. 213°. In a similar manner alanine gives 65% of alacreatine, whose *picrate*, yellow, m. 187°. Sarcosine gives 40% of creatine, whose *picrate* m. 218–20°. C. J. West

Unsaturated anhydrosugars. IV. 2-Oxygalactal and the preparation of kojic acid (2-hydroxymethyl-5-hydroxy-γ-pyrone). Kurt Maurer and Artur Müller. *Ber.* **63B**, 2069–73(1930); cf. *C. A.* **24**, 2112.—The synthesis of kojic acid (I) from glucose was described in Paper III. A similar synthesis has now been effected from galactose. 2,3,4,6-Tetraacetyl-2-oxygalactal (II) shows the same properties as the oxyglucal; like the latter, it loses its Ac groups when treated with $PhNHNH_2$, yielding galactosazone. Oxidative cleavage of the double bond with $KMnO_4$ gives the K salt of acetylated lyxonic acid, converted by sapon., through the Pb salt, into lyxonolactone (III). II takes up Cl in abs. Et_2O, forming, among other products, a dichlorotetraacetyl-2-oxygalactal, which could not be obtained in cryst. form but with Ag_2CO_3 and H_2O yielded the beautifully crystd. tetraacetylgalactosone hydrate (IV). IV reduces Fehling soln. at room temp., decolorizes cold $KMnO_4$ and shows mutarotation. With NaOH it forms galactosone, yielding galactosazone with $PhNHNH_2$ at 20°. With C_5H_5N-Ac_2O, IV gives the diacetate of I in good yield. It is worthy of note that, although the arrangement of the substituents on C atom 4 is the reverse of that in the glucose deriv., this does not interfere with the splitting off of the AcOH from IV. II, obtained in 3–4 g. yield from 40 g. acetobromogalactose, m. 111°, $[\alpha]_D^{18}$ 5.03° (EtOH).

9.90° (MeOH), —3.84° ($CHCl_3$), —12.68° ($(CHCl_2)_2$). K lyxonate, m. 166°, $[\alpha]_D^{19}$ (0.1732 g. in 8.65 cc. 0.1 *N* HCl made up to 10 cc.) 8.91° immediately after soln., 41.73° (const.) after 7 days. IV (2.2 g. from 5 g. II), m. 96°, $[\alpha]_D^{20}$ 45.68° ($CHCl_3$; no mutarotation). In aq. solns. its rotation slowly decreases: $[\alpha]_D^{20}$ in H_2O 98.90° decreasing to 1.35° in 105 days, in NH_4OH 80.77° changing to 4.55° in 88 days, in HCl 113.17° changing to 3.42° in 75 days. C. A. R.

Highly polymerized compounds. XXXIX. Cellulose. H. STAUDINGER, K. FREY, R. SIGNER, W. STARCK AND G. WIDMER. *Ber.* 63B, 2308–16(1930); cf. *C. A.* 24, 5717.—A review with 68 references. **XL. Viscosity measurements on polysaccharides and their derivatives.** H. STAUDINGER AND O. SCHWEITZER. *Ibid* 2317–30.—Data are given for inulin, lichenin and starch in $HCONH_2$, acetylcellulose in CCl_4 and *m*-MeC_6H_4OH, cellulose benzyl and Me ethers in CCl_4 and the Me ether in H_2O, and for nitrocellulose in BuOAc. 78 references are given. **XLI. Molecular-weight determinations on acetylcelluloses.** H. STAUDINGER AND H. FREUDENBERGER. *Ibid* 2331–43.—The relative viscosity of acetylcellulose decreases from 213 to 2.26 when the acetylation time is increased from 6 to 120 hrs. at 60° and from 20.9 to 3.11 when the time is increased from 0.75 to 6.25 hrs. at 80°; the corresponding changes in mol. wts. are from 18,400 to 2200 and from 8200 to 2200. Other data are given for products prepd. by different methods. The nature of the colloidal solns. of cellulose acetates is discussed. C. J. WEST

Chemistry of the three-carbon system. XXV. Effect of the methyl group on the tautomerism of acids and ketones of the cyclopentane and cyclohexane series. GEO. A. R. KON AND RAM SIMHA THAKUR. *J. Chem. Soc.* 1930, 2217–31; cf. *C. A.* 24, 3213.—α-Cyclohexylidenepropionic acid gives an *anilide*, m. 126°, and a *p-toluidide*, m. 161°; α-Δ¹-cyclohexenylpropionic acid, b_1 120–4°, m. 38°, $d_4^{20.6}$ 1.0332, $n_D^{20.6}$ 1.48405; Et ester, b_{19} 111°, $d_4^{19.7}$ 0.9660, $n_D^{19.7}$ 1.4627; anilide, m. 123–4°; *p-toluidide*, m. 108°; the equil. mixt. contains 32% α,β-acid; the mobility is approx. 0.0075. 2-Methylcyclohexylideneacetic acid m. 68.5°; *amide*, m. 112°; *anilide*, m. 99°; 2-methyl-Δ¹-cyclohexenylacetic acid yields an *amide*, m. 138°, and an *anilide*, m. 143°; the equil. value is about 11.3% α,β-acid; the mobility is 0.15 and the half-change period 59 hrs. 3-Methylcyclohexylideneacetic acid, m. 90°; *amide*, m. 143–4°; *p-toluidide*, m. 136°; 3-methyl-Δ¹-cyclohexenylacetic acid, m. 38°; the equil. mixt. contains about 8% of α,β-acid; the mobility is 0.27 and the half-change period is about 26 hrs. 4-Methylcyclohexylideneacetic acid, m. 66°; *p-toluidide*, m. 119°; 4-methyl-Δ¹-cyclohexenylacetic acid, m. 42–3°; *p-toluidide*, m. 111°; the mean equil. value is about 7%; the mobility is 0.42, the half-change period 17 hrs. α-Methyl-Δ¹-cyclopentenylacetic acid b_1 113–5°, $d_4^{19.4}$ 1.0366, $n_D^{19.4}$ 1.47497; the Et ester b_{10} 82–3°, $d_4^{18.4}$ 0.9616, $n_D^{18.4}$ 1.45393; the mean equil. value is 38% of α,β-acid; the mobility is 0.58 and the half-change period 14 hrs. The α-Me group causes appreciable shifting of the equil. towards the α,β-side in both the cyclopentane and the cyclohexane series; it also retards the mobility of the system so greatly that only approx. measurements were possible in some cases. The introduction of a Me group in the cyclohexane ring has a general slight retarding effect on the mobility but it has practically no effect on the position of equil. which is displaced towards the β,γ-side to a slight extent. All attempts to prep. the α,β-isomer of α-methyl-Δ¹-cyclohexenylacetone by the Blaise-Maire or Grignard reaction were fruitless. The same is true of the 2-Me isomer; condensation with $CHNa(CO_2Et)_2$ in EtOH gives *Et 2-methylcyclohexanespirocyclohexane-3,5-dione-6-carboxylate*, m. 134°. *3-Methylcyclohexylideneacetone*, b_{6-7} 91–3°, $d_4^{18.3}$ 0.9235, $n_D^{18.3}$ 1.48571; *semicarbazone*, m. 191°. 3-Methyl-Δ¹-cyclohexenylacetone, b_{7-8} 86–8°, $d_4^{16.8}$ 0.9200, $n_D^{16.8}$ 1.46986; the equil. mixt. contains about 25% α,β-isomer. Condensation of the β,γ-ketone with $CHNa(CO_2Et)_2$ gives a product which is hydrolyzed to *3-methylcyclohexanespirocyclohexane-3,5-dione*, m. 135–6°. *4-Methylcyclohexylideneacetone*, b_9 94°, $d_4^{16.8}$ 0.92694, $n_D^{16.8}$ 1.48594; *semicarbazone*, m. 176–7°. 4-Methylcyclohexenylacetone, b_8 85°, $d_4^{16.3}$ 0.9178, $n_D^{16.3}$ 1.46836. The equil. mixt. contains about 13.5% α,β-isomer; the mobility varies from 600–700. *4-Methylcyclohexanespirocyclohexane-3,5-dione*, m. 168°. α-Methylcyclopentylideneacetone, b_{11} 95.5–6°, d_4^{19} 0.9601, n_D^{19} 1.49737; α-methyl-Δ¹-cyclopentenylacetone, b_{10} 74°, d_4^{19} 0.9216, n_D^{19} 1.4635; the equil. mixt. contains 64% α,β-isomer; the mobility is about 3000. Condensation with $CHNa(CO_2Et)_2$ by heating 4 days gives a small amt. of an oily ester hydrolyzed to *cyclopentanespiro-2-methylcyclohexane-3,5-dione*, m. 118–9°. The introduction of an α-Me group displaces the equil. in these ketones

toward the β,γ-side in both cyclohexane and cyclopentane series, *i. e.*, its effect is the reverse of that observed in the acids. It does not appear to affect mobility to a great extent. The effect of the Me group in the *m*- and *p*-position of the cyclohexane ring is not very pronounced; but in the *o*-position it appears to exercise considerable influence in the stabilization of the β,γ-phase to the almost exclusion of the α,β.
C. J. WEST

Action of reduced nickel and hydrogen on aromatic hydrocarbons under high pressure and temperature. TORU OGAWA AND TOSHIO YOKOTA. *Bull. Chem. Soc. Japan* **5**, 266–75(1930).—C_6H_6 (100 g.) and 5 g. reduced Ni and H, heated 1 hr. at 470° under pressure of 80 atm. at 0°, showed a depression of H of 35 atm. at 0° (2.7 mol. %); the gas in the autoclave contained 98.5% H, 1.2% N, 1.4% satd. hydrocarbons and 0.1% CO; the liquid reaction product (92%) was cyclohexane, which is stable under the above conditions. C_6H_6 and Ni, heated with H at 500° and 100 atm., gave 28% gas, 41% liquid hydrocarbons and 14% coke; the gas consisted of 94.5% CH_4 and 5.5% H; the liquid boiled from 48 to 320° and contains C_6H_6 and PhMe. C_6H_6 at 200° and 100 atm. for 2 hrs. and then at 500° for 3 hrs. gives 5.4% CH_4 and a mixt. of cyclopentane, methylcyclopentane and cyclohexane. Pure $C_{10}H_8$, heated with H at 460–500° and 80 atm., with or without Fe_2O_3 or CuO, showed no reaction; with Ni there resulted 5% CH_4 and 91% of a liquid, composed of C_6H_6 homologs and tetralin. Tetralin, treated as in the case of $C_{10}H_8$, gives 5.6% CH_4 and 92% of a liquid consisting of C_6H_6 homologs and decalin. Decalin gives cyclohexane and its homologs.
C. J. WEST

Action of fuming sulfuric acid on hexane, cyclohexane and some of their derivatives. GEO. N. BURKHARDT. *J. Chem. Soc.* **1930**, 2387–99.—When an excess of hexane (I), cyclohexane (II) or methylcyclohexane (III) is stirred vigorously with fuming H_2SO_4 (35 or 65% SO_3) at 0–10° for 4–5 hrs., practically the whole of the SO_3 is used in the reaction which takes place. In most of the smooth reactions, about 1 mol. SO_2 was formed per mol. of hydrocarbon attacked; it is clear that the oxidation of some of the H of the hydrocarbon is an important part of the reaction but it is not clear whether this is the primary reaction or whether sulfonation precedes oxidation. Cyclohexanesulfonic acid is very readily oxidized by 20% oleum under similar conditions and it appears that sulfonation can occur without oxidation. The general nature of the products formed was deduced from the chem. properties and analyses of the mixed Ba salts and sulfonyl chlorides. The Ba salt of the hydrolyzed product from I contained 2 mol. proportions of disulfonate per mol. of monosulfonate; 5% of the I chains were unsatd. and it appears that about 30% of the I chain contained a HO group; the HO groups were very largely or entirely in the form of H_2SO_4 esters in the first product. Similar proportions of the corresponding alicyclic sulfonic acids were formed from II together with a small % of $PhSO_3H$. Cyclohexene and concd. H_2SO_4 give some cyclohexanol and Ba cyclohexyl sulfate; with 35% oleum only the Ba salt was isolated. Cyclohexanol and 25% oleum, followed by 70% oleum, give polymerized cyclohexene and a Ba salt, probably contg. a large proportion of sulfatosulfonic acid and perhaps disulfonic acid. Cyclohexanol (IV) and 12% oleum below 20° or $ClSO_3H$ in $PhNMe_2$ give *cyclohexylsulfuric acid*, whose *Na salt*, plates, crystallizes with 1 mol. H_2O and *Ba salt*, brilliant plates, with 4 mols. H_2O. The salts are rapidly hydrolyzed to IV by boiling dil. mineral acid but not readily below 80–90°; it is unaffected by boiling neutral aq. $KMnO_4$ in 15 min. and in dil. soln. is only rapidly attacked by CrO_3-H_2SO_4 mixt. at the b. p. The salts of cyclohexanesulfonic acid are discussed.
C. J. WEST

New orientation rule and the anomaly of the nitroso group. DALZIEL L. HAMMICK AND WALTER S. ILLINGWORTH. *J. Chem. Soc.* **1930**, 2358–64.—The facts as to the orienting influence of single atoms and groups present in the C_6H_5 nucleus on further substitution can be expressed, without any theoretical implications whatever, by the following rule: If in the C_6H_6 deriv. PhXY, Y is in a higher group of the periodic table than X, or if, being in the same group, Y is of lower atomic wt. than X, then a 2nd atom or group of atoms that enters the nucleus will go in the *m*-position to the group XY. In all other cases, including that in which the group XY is a single atom, a 2nd entering atom or group goes to the *o*- and *p*-positions. The effect of ionic charges on XY is given by the statement that a positive charge directs *m*- and a negative charge directs *o*- and *p*-. Examples are given of the application of the rule. The 1 apparent exception to this rule is the NO group, since nitration and bromination of PhNO in CS_2 and CCl_4 give *p*-derivs. PhNO in CS_2 over the range studied has an av. degree of assocn. of 18%; in dil. soln. in AcOH it is entirely unimol. PhNO in CS_2 gives the *p*-Br deriv rapidly at —5°; negative results were obtained in AcOH; after 24 hrs. Br and

PhNO in AcOH contg. excess AcONa give a *tribromoazoxybenzene*, m. 123°. It thus appears that the rapid production of *p*-substituted PhNO occurs only when expt. shows that the PhNO is present to some extent in the bimol. form. The solid equil. curve for AcOH-PhNO shows no indication of compd. formation. Expts. indicate that the reactivity of the halogen in the Br-substituted PhNO is in accordance with the view that the NO group is *m*-directing when present in the unimol. form. C. J. WEST

Reaction between keto-anils and Grignard reagents and the tautomerism of aliphatic keto-anils. WALLACE F. SHORT AND JOHN S. WATT. *J. Chem. Soc.* **1930**, 2293–7.—Aliphatic keto-anils react with MeMgI in Am_2O to give 1 mol. CH_4 and, since practically the whole of the anil may be recovered by decompn. of the resulting Grignard complex, these anils must be capable of reacting in the enamic form: :C:CRNH.-Aryl. Acetone anil (I), m. 23.5°, d_4^{20} 1.0087, n_D^{20} 1.5886 (supercooled); PhMgBr and 13 g. I give a product which, decompd. with NH_4Cl, gives 3 g. C_6H_6, $PhNH_2$ and a little I in the fraction b_{18} up to 128° but the main fraction is pure I. The product from I and EtMgBr reacts with Me_2SO_4 to give CH_2:CMeNMePh, b_{18} 146°, d_4^{20} 1.0030, n_D^{20} 1.5856. I, $PhCH_2Cl$ and C_6H_6 give the *HCl salt*, m. 195° (decompn.), of *benzylisopropenylaniline*, m. 22–3°; the HCl salt is immediately decompd. by cold dil. Na_2CO_3. The values of $[R_L]_D$ indicate that I exists mainly in the enamic phase and is the first simple instance of the tautomeric system :CHC:N ⟷ :C:C.NH. PhC(:NPh)-Me and PhMgBr give dypnone anil, m. 97° (cf. Plancher and Ravenna, *Atti. accad Lincei* 15, ii, 555(1906)), which results from the condensation of 2 mols. PhC(:NPh) Me under the influence of the Grignard reagent, since EtMgBr gives the same product. Benzophenone anil is recovered after its vigorous reactions with Grignard reagents. C. J. WEST

Compounds with iodoform, bromoform and chloroform with quaternary and ternary salts. IV. WILHELM STEINHOPF AND HERBERT TEICHMANN. *J. prakt. Chem.*. 127, 337–56(1930); cf. *C. A.* 20, 2815.—$Et_2Ph(PhCH_2)NI$, m. 120°, gives *compds.* with CHI_3, yellow, m. 120°, with $CHBr_3$, m. 114–6°, and with $CHCl_3$, m. 105°. $Me_2(PhCH_2)_2NI$ yields a *compd.* with $CHBr_3$, light yellow, m. 108°. $(PhCH_2)_3NHI$, m. 189°, for which a convenient method of prepn. is given, gives a *compd.* with $3CHBr_3$, m. 82°. *Diethylbenzylphenylarsonium iodide*, m. 149°, in 100% yield from Et_2PhAs and $PhCH_2I$, gives a yellow *compd.* with CHI_3, m. 122°, and a yellow *compd.* with $CHBr_3$, m. 113°. *Ethylbenzyldiphenylarsonium iodide*, m. 178°, gives a bright yellow *compd.* with CHI_3, m. 101–8° (could not be crystd. from EtOH), and a pale yellow *compd.* with $CHBr_3$, m. 125–55°. Et_3SI and CHI_3 give a light yellow *compd.* in the ratio 2:3, m. 127°; this also results from Et_3SOH and CHI_3. The *compd.* $Et_3SI.CHI_3$ results on mixing the components in mol. ratios and m. 139°; recrystn. from EtOH gives the compd. m. 128°. Only 1 *compd.* results with $CHBr_3$ (1:1), m. 98–100°. Me_2SI (m. 208–13°) and CHI_3 form a *compd.* in the ratio of 1:2, m. 152°; the compd. with $CHBr_3$ decompd. so easily that it was not analyzed. The *compd.* $Me_2EtSI.2CHI_3$, yellow, m. 136°; the *compd.* $Me_2EtSI.CHBr_3$ m. 35–40° and is decompd. by cold H_2O. Choline iodide and CHI_3 give a *compd.* in the ratio of 2:3, m. 195°. *Trimethylaminoacetic acid-HI*, $C_{10}H_{23}O_4N_2I$, m. 240–1° (decompn.). A table of known addn. compds. is given. C. J. WEST

Polynitroarylnitroamines. I. 2,4,6-Trinitrophenylnitroamine. WM. W. JONES AND FRANCIS G. WILLSON. *J. Chem. Soc.* 1930, 2277–9.—Nitration of *p*-$H_2NC_6H_4SO_3H$ in H_2SO_4 at 15°, stirring for 24 hrs. and standing for 48 hrs. at 20°, gives 75% of *2,4,6-trinitrophenylnitroamine* (I), yellow, deflagrates between 80–110°; the alk. soln. is deep purple-red, from which well-defined salts can be isolated. The constitution is shown by the conversion into the Me deriv., m. 115–20°, with Me_2SO_4; by its decompn. in the Lunge nitrometer with quant. liberation of NO_2; by its formation from picramide (II) by nitration; and by the formation of II, in practically quant. yield, when dissolved, with an equimol. amt. of 2,4-$(O_2N)_2C_6H_3NH_2$, in cold concd. H_2SO_4. Nitration of 2,6-$(O_2N)_2C_6H_3SO_3H$ gives 55% of I. Nitration of *p*-$O_2NC_6H_4NH_2$ likewise gives I (cf. Macciotta, *C. A.* 24, 4279). C. J. WEST

Action of ferric chloride on *o*-, *m*- and *p*-toluidine. WM. H. PATTERSON. *J. Chem. Soc.* 1930, 2401.—*o*-$MeC_6H_4NH_2$ with HCl and $FeCl_3$ gives a dark bluish green ppt. with purple reflex; the *m*-isomer gives a brown color and then a ppt.; the *p*-isomer gives an intense plum-red color. The reaction of the *m*-isomer with excess $FeCl_3$ at room temp. is complete after 28 days; the wt. of the ppt. is about half that of the toluidine; the ppt. obtained after 7 days from a mixt. of the *o*- and *p*-isomers (69.5% of the former) is 32% of the wt. of the *o*-isomer; the content of the *p*-isomer in the

residual mixt. is 37.6%. These complexes contain no Fe and burn without melting when heated in air. C. J. WEST

Tertiary arylalkylphosphines. I. IVOR K. JACKSON, WALTER C. DAVIES AND WM. J. JONES. *J. Chem. Soc.* 1930, 2298–301.—The following derivs. were prepd. from *p*-$EtC_6H_4PCl_2$ or *p*-$MeOC_6H_4PCl_2$ and the proper Grignard reagent: *p-Ethylphenyldipropylphosphine*, b_{21} 157°, d_4^{25} 0.9147, n_F^{25} 1.5370, n_D^{25} 1.5255, n_C^{25} 1.5208; *dibromide*, oily. The *di-Bu deriv.* b_{15} 176°, d_4^{25} 0.9042, n^{25} 1.5319, 1.5208, 1.5162 for F, D and C; the *dibromide* is oily. The *di-Am deriv.* b_{18} 201°, d_4^{25} 0.9022; *mercurichloride*, m. 95°. *p*-Ethylphenylmethyldipropylphosphonium hydroxide is an oil; the soln. reacts alk. and ppts. the difficultly sol. metallic hydroxides from solns. of their salts; the *chloroplatinate*, yellow, m. 195°; the corresponding *di-Am deriv.*, yellow, m. p. unsharp. *p-Methoxyphenyldipropylphosphine*, b_{17} 165°, d_4^{25} 0.9738, n^{25} 1.5477, 1.5352, 1.5301 for F, D and C; *dibromide*, thick liquid; *mercurichloride*, m. 134°. The *methiodide* m. 60°. The *di-Bu deriv.* b_{16} 190°, d_4^{20} 0.9600, n^{25} 1.5389, 1.5274, 1.5226 for F, D and C; *methiodide*, m. 86°. The hydroxide is an oil, which yields a *chloroplatinate*, yellow, m. 196°. The *di-Am deriv.* b_{18} 202°, d_4^{25} 0.9382, n^{25} 1.5289, 1.5178, 1.5132 for F, D and C; *dibromide*, m. about 85°; *mercurichloride*, m. 114°; methiodide, oily; *chloroplatinate*, yellowish brown, m. 153°. The rate of oxidation of these phosphines is comparatively slow. The at. refractivity for P, calcd. from the above values of *n*, ranges from 10.15 to 10.65, which, compared with the value of 9.47 for Et_3P, shows the great optically exaltative effect of the linking of the Ph group to P. C. J. WEST

Action of hydrobromic acid on certain arsonic acids. MONTAGUE A. PHILLIPS. *J. Chem. Soc.* 1930, 2400–1.—Boiling the following benzenearsonic acids with 3–4 times their wt. of HBr (d. 1.445) gives the following products: 3,4-$O_2N(H_2N)$, 4,2-Br-$(O_2N)C_6H_3NH_2$ (97%); 4,3-$O_2N(H_2N)$, 5,2-$Br(O_2N)C_6H_3NH_2$ (96%); 3,4-O_2N-(MeNH), 4,2-$Br(O_2N)C_6H_3NHMe$ (92%); *4-nitro-3-methylamino*, yellow plates, 5,2-$Br(O_2N)C_6H_3NHMe$ (80%); 3,4-$O_2N(HO)$, mixt. of polybrominated nitrophenols, from which 20% of 2,4,6-$Br_2(O_2N)C_6H_2OH$ was isolated; 3,4-$H_2N(HO)$, 4,2-$Br(H_2N)$-C_6H_3OH (about 20%); 3,4-AcNH(HO), the same product as before; 4,3,5-H_2N-$(O_2N)_2$, 4,2,6-$Br(O_2N)_2C_6H_2NH_2$ (96%). No decompn. occurred with the 6,3-O_2N-(H_2N) deriv. The 4,3-$O_2N(HO)$ and 2,3-$O_2N(HO)$ derivs. gave mixts. which could not be sepd. C. J. WEST

Direct meta-substitution in the toluene nucleus. JOHN B. SHOESMITH AND JOHN F. MCGECHEN. *J. Chem. Soc.* 1930, 2231–6.—The reaction between Me_3CCl and PhMe with $AlCl_3$ gives *m*- and *p*-$Me_3CC_6H_4Me$ in the ratio of 62:38; in the presence of $FeCl_3$ the ratio is 67:33; in the presence of $PhNO_2$-$AlCl_3$, 67:33; details of the analysis are given, 1 method being based on the marked difference in the solubilities of the *Ba sulfonates* of the hydrocarbons. BuCl and PhMe with $AlCl_3$ give a mixt. of *m*- and *p*-$MeEtCHC_6H_4Me$ in the ratio of 75:25. The synthesis of these 2 compds. from *m*- and *p*-$MeC_6H_4C(OH)MeEt$ is described. *m-sec-Butyltoluene-?-sulfonyl chloride* b_{11} 164–5°; *anilide* m. 120.5–1°; the corresponding *p-derivs.* b_{12} 162–4° and m. 124.5–5°, resp. C. J. WEST

Aromatic sulfonyl fluorides. II. WILHELM STEINKOPF AND PAUL JAEGER. *J. prakt. Chem.* 128, 63–88(1930); cf. *C. A.* 21, 3603.—In the first work it was shown that the sulfonyl fluorides were stable toward H_2O, acids and NH_4; it is now shown that they are also stable toward metals such as Cu and Mg. *m*-$IC_6H_4SO_2F$ and Cu, heated 6 hrs. at 200–30°, give 54% of *3,3'-biphenyldisulfonyl fluoride*, m. 133–4°; Cl-SO_3H gives the chloride, m. 127–8.5°. *2-Iodotoluene-4-sulfonyl fluoride*, m. 35–6°, results from the NH_2 deriv. through the diazo reaction; with Cu at 220° there results 41% of *2,2'-dimethylbiphenyl-5,5'-disulfonyl fluoride*, m. 146–7°; with Me_2NH in EtOH there results the *dimethylamide*, m. 244–7°. *2-Iodoanisole-4-sulfonyl fluoride*, m. 58–8.5°; Cu at 220° for 10 hrs. gives *2,2'-dimethoxy-5,5'-biphenyldisulfonyl fluoride*, m. 205.6°. Aminomesitylenesulfonyl fluoride, m. 62°, results by the reduction of the NO_2 deriv. by Sn and concd. HCl. *Dinitromesitylenesulfonyl fluoride*, m. 157–8°, results quant. on nitrating with HNO_3-H_2SO_4 at 20–5°; reduction gives the *di-NH_2 deriv.*, m. 142–3°. $PhSO_2F$ and MeMgI in Et_2O give *methylphenyl(phenylsulfonyl)sulfanic acid*, $PhSO_2SMe(O_2H)Ph$, m. 123–4°, stable at 260–300° (*K salt; Me ester*, m. 102–3°), and $MeSO_2Ph$, m. 87–8°. $PhSO_2F$ and PhMgBr give Ph_2 and Ph_2SO_2. 2,4-$(FO_2S)_2$-C_6H_3Me and PhMgBr give a mixt. of *2,4-di(phenylsulfone)toluene*, m. 192°, and *tolyl-(2- or 4-phenylsulfone)-4- or 2-diphenylsulfonic acid*, decompg. 125–6°. 3-$H_2NC_6H_4$-SO_2F in EtOH, concd. H_2SO_4 and $AsCl_3$, treated with $NaNO_2$ at 5–10°, give *phenylarsonic acid-3-sulfonyl fluoride*, m. 160°; the *amide* does not m. 300°; reduction of

the acid with SO_2 in HCl gives the *dichloride*, b_{10} 183–4°, m. 42°; with $AlCl_3$ in CS_2 there results *phenyldichloroarsine-3-sulfonyl chloride*, b_{10} 200–5°, m. 61–2.5°. *Diphenylarsinic acid-3-sulfonyl fluoride*, m. 150–2° (34.8% yield); reduction gives 81% of *diphenylchloroarsine-3-sulfonyl fluoride*, b. (high vacuum) 168–79°. 2,4-$Me(FO_2S)$-C_6H_3OH in FSO_3H, heated 2–2.5 hrs. at 80–90°, give 15% of *2,2'-dimethylphenylene-o-sulfonylide-4,4'-disulfonyl fluoride*, decomps. over 240°. The *m*-isomer and FSO_3H, heated 2 hrs. at 80–90°, give *m-cresoldisulfonyl fluoride* (I), 3,2,4- or 3,4,6-$Me(FO_2S)_2$-C_6H_2OH, m. 125–6.5°; *NH_4 salt*, m. 163–5°; liquid NH_3 at room temp. for 3 days gives *m-cresoldisulfonamide*, m. 244–5.5°; I and concd. HNO_3 give the *NO_2 deriv.*, light yellow, m. 99–100°. 4,3-$HO(FO_2S)C_6H_3Me$ and FSO_3H, heated 2 hrs. at 80–90°, give 65% of *4,4'-dimethylphenylene-o-sulfonylide-6,6'-disulfonyl fluoride*, decomps. 260–5°; treated with liquid NH_3 for 3 days, there results *3-hydroxytoluene-3,5-disulfonamide*, m. 219.5–20.5°. 3,5-$Me_2C_6H_3OH$ and FSO_3H 6 hrs. at 0° give a *sulfonyl fluoride*, m. 107–8°; liquid NH_3 gives a *sulfonamide*, m. 161–2°. 2,4-$Me_2C_6H_3OH$ gives a *sulfonyl fluoride*, b. (high vacuum) 71–3°; attempts to prep. a disulfonyl fluoride gave *4,6,4',6'-tetramethylphenylene-o-sulfonylide*, decomps. 243–5°. *o*-ClC_6H_4OH gives 30% of a *sulfonyl fluoride*, m. 83–4°. $PhSO_2F$ and BzONa, heated 16 hrs. at 240°, give a mixt. of Bz_2O and BzF, which with $PhNH_2$ gives BzNHPh. C. J. West

The nitration process. III. Nitration of *o*- and *m*-cresol. Stig. Veibel. *Ber* **63B**, 2074–82(1930); cf. *C. A.* **24**, 4512.—Using the same methods as in the nitration of PhOH, the following results were obtained with *o*- and *m*-cresol at 25°. The dropping pipet held 470 × 10^{-4} mol. of the *o*-cresol (liquefied by adding 11 g. H_2O to 200 g. of the cresol) and 480 × 10^{-4} mol. of the *m*-cresol. The yields are expressed in mol × 10^{-4}. In designating the nitrocresols, the HO group is taken as being in position 1.

The yields of condensation product are based on the assumption of a mol. wt. of 227, corresponding to a dimethylindophenol. With *o*-cresol, the yield of nitrocresols at first increases in the more dil. HNO_3 (1–1.5 *N*) with increase in the length of dropping and that of condensation product decreases, whereas in the more concd. HNO_3 (2–3

N) the reverse is true; this difference is probably due to a nitration of the condensation product, with consequent increase in its wt., in the more concd. acid. The av. value of the ratio [increase 6-NO_2 deriv.]/[increase 4-NO_2 deriv.] is 3.61:1. Assuming that 3.61/4.61 = 0.78 of the nitrocresol part of the condensation product was on the way to the formation of the 6-NO_2 deriv. and 1/4.61 on the way to the formation of the 4-NO_2 deriv., the yields of the NO_2 derivs. found should be corrected by the addn. of 0.39 and 0.11, resp., of the condensation product; when so corrected the ratio of 6- to 4-nitro deriv. becomes 0.965, 1.07, 1.08, 1.06 in 1, 1.5, 2 and 3 *N* HNO_3, resp. In the nitration of *m*-cresol, 2 *o*-NO_2 derivs. are formed, but in this paper they were detd. together and are reported as the 6-NO_2 deriv. The titration of the *p*-compd. (4-nitro-*m*-cresol) with Br is not as accurate as that of the other nitrophenols studied and a correction factor, depending on the excess of Br used, must be applied. The ratio increase 6- to increase 4-NO_2 deriv. is 1.56 and the yields of 6- and 4-NO_2 derivs. found should be corrected by the addn. of 0.3 and 0.2, resp., of the condensation product. The cor. ratio 6- to 4-NO_2 deriv. becomes 0.655, 0.64, 0.625, 0.605 in 1, 1.5, 2 and 3 *N* HNO_3, resp. The chief results of this investigation are that the nitration of *o*-cresol yields the 6- and 4-NO_2 derivs. in about the ratio 1:1. The ratio is not changed by changes in the initial concn. of the HNO_3 but seems to increase slightly with increasing concn. of the HNO_3. With *m*-cresol the yield of 6-NO_2 + 2-NO_2 to 4-NO_2 deriv. is 2 3 and is not influenced by changes in the concn. of the HNO_3 and HNO_2.

C. A. R.

Influence of the sulfur atom on the reactivity of adjacent atoms or groups. IV. Direct polar effects. G. Macdonald Bennett and A. Neville Mosses. *J. Chem. Soc.* 1930, 2364–9; cf. *C. A.* 24, 1339.—Previous work has shown that the HO group situated in the δ-position to a S atom was much more reactive with HBr than 1 in the γ-position. The possibility that the hydroxy sulfide might have been converted directly into the cyclic sulfonium hydroxide before reacting with HBr is disposed of by the fact that $PhS(CH_2)_4OH$ has no tendency to ring closure at 100°; a 2nd possibility that the hydroxy sulfide might have been converted into the sulfonium bromide without the intermediate formation of the open-chain bromo sulfide is disposed of by the comparative reaction of HCl upon the γ- and δ-compds.; The γ-deriv. reacted to the extent of 3.7%, while the δ-compd. gives 33.2% of *1,4-diphenylthiolbutane*, m. 85°, also obtained by the action of PhSNa on $PhS(CH_2)_4Cl$ in EtOH. $PhS(CH_2)_3OH$ and $PhS(CH_2)_4OH$ with excess fuming HBr at room temp. show about 1.16% conversion into the bromo sulfides, while $PhS(CH_2)_4OH$ gives *phenyltetramethylenesulfonium bromide*, analyzed as the *bromoaurate*, dark red, m. 120° (decompn.). The direct polar effect of the Me group is discussed.

C. J. West

The constitution of some dibromophenetidines. G. Bargellini with Lydia Monti and Antonio Grippa. *Gazz. chim. ital* 60, 559–72(1930); cf. *C. A.* 24, 4771.—Both as a continuation of earlier expts. on the prepn. of dichlorophenetidines (*Gazz. chim. ital.* 59, 16(1929); cf. *C. A.* 23, 1630) and because of the contradictory results obtained by Staedel (*Ann.* 217, 67(1883)) and Jackson and Fiske (*Ber.* 35, 1130(1902)) on the prepn. and properties of 2,6,4-$Br_2(H_2N)C_6H_2OEt$ (I), expts. were carried out on the prepn. of the di-Br derivs. of phenetidine by the method used for the di-Cl derivs., and the prepn. of derivs. of these dibromophenetidines. 2,6,4-$Br_2(O_2N)C_6H_2OH$ (II) was prepd. by the method of Möhlau and Uhlmann (*Ann.* 289, 94(1896)). $Na_2S_2O_4$, added slowly to aq. alk. II on a boiling water bath until the liquid remains permanently colorless, cooled, acidified with AcOH and the ppt. recrystd. from boiling C_6H_6, yields I, m. 191–3°. I (3 g.), AcONa (2 g.) in EtOH (30 cc.) and $ClC_6H_3(NO_2)_2$ (2.3 g.), refluxed 3 hrs., cooled, and the ppt. recrystd. repeatedly from boiling EtOH, yield *1-hydroxy-2,6-dibromo-2,4'-dinitrodiphenylamine*, red, m. 213–5°, which is easily electrified by rubbing with glass. When refluxed, I and piperonal (III) (equimol. quantities) in EtOH form a black resinous product, probably through oxidation of I. But I (2 g.) and III (1.1 g.) heated without solvent at 100° in CO_2 for 2–3 hrs., the product dissolved in boiling EtOH and cooled, ppts. *piperonal-2,6-dibromo-4-aminophenol*, yellowish, m. 150–2°. I and BzH in EtOH also form a black resin, but I and BzH (equimol. quantities), heated in CO_2 at 100°, the product dissolved in boiling petr. ether, cooled, and the ppt. purified by repeating this process, form *benzylidene-2,6-dibromo-4-aminophenol* (IV), 3,5,4-$Br_2(HO)C_6H_2N:CHPh$, rose color, m. 94–5°. Excess EtI (10 g.), added to a mixt. of IV (10 g.), KOH (2 g.) and EtOH (30 cc.), refluxed 4–5 hrs., the EtOH removed by distn., the residue dissolved in water, extd. with Et_2O, the ext. evapd., the oily residue (which could not be purified) hydrolyzed by refluxing with HCl (1:1) for 30 hrs., dild. with water, extd. with Et_2O to remove BzH and other unaltered products, the aq. soln. neutralized with NH_4OH, steam-distd., and the distd. product recrystd.

from boiling petr. ether, gives a small yield of **I**, m. 108°. The analysis and m. p. show that this is identical with the compd. of Jackson and Fiske (*loc. cit.*). Attempts to obtain a higher yield of I by modifying the conditions described above, by heating with EtI in a closed tube and by using Et_2SO_4 instead of EtI, gave very small yields. Aq. $AgNO_3$, added to **II** in dil. NH_4OH, filtered, washed with water, the residue refluxed with excess alc. EtI for 2–3 hrs., filtered, the filtrate evapd., and the residue recrystd. from EtOH, yields *dibromo-p-nitrophenetole* (**V**), yellowish, m. 59°. **V** (20 g. in 200 cc. of EtOH), NaS (40 g.) and S (5 g.), refluxed 4–5 hrs., evapd., the residue dissolved in water, steam-distd., and the distillate purified by crystn. from petr. ether, yield 2,6,4-$Br_2(H_2N)C_6H_2OEt$ (**VI**), m. 107–8° (cf. Jackson and Fiske, *loc. cit.*). To avoid the formation of a di-Ac deriv., **VI** in C_6H_6 was treated with AcCl (calcd. quantity) in C_6H_6 and the ppt. recrystd. from dil. EtOH, which yields 2,6,4-$Br_2(AcHN)C_6H_2OEt$, m. 198° (cf. Fuchs, *Monatsh.* **38**, 331). A higher yield of 3,5,6-$Br_2(H_2N)C_6H_2OEt$ (**VII**) than that obtained by the method of Fuchs (*Monatsh.* **38**, 113, 331) was obtained by adding Br (24 g.) in $CHCl_3$ (50 cc.) to phenetidine (10 g.) (keeping the mixt. ice-cold), evapg. on a water bath, steam-distg. the residue, and purifying the distillate by crystn. from dil EtOH, which yields 7 g. of **VII**, m. 79°. No condensation products of **VII** with BzH, **III**, $ClC_6H_3(NO_2)_2$, etc., could be obtained, which is in accordance with the behavior of 3,5,6-$Cl_2(H_2N)C_6H_2OEt$, *i. e.*, the 2 halogen atoms in *o*-position to NH_2 exercise a steric hindrance, in the face of which the NH_2 is incapable of reacting with the compds. mentioned. **VII** in C_6H_6 and AcCl (the calcd. quantity or a little more) in C_6H_6 form a ppt. which, recrystd. from dil. EtOH, yields the mono-Ac deriv. (**VIII**) of **VII**, softens at 130°, m. 144° (cf. Fuchs, *loc. cit.*). **VII**, boiled with excess Ac_2O for a few min., poured into water and the ppt. recrystd. from EtOH, yields a *di-Ac deriv.* of **VII**, $C_{12}H_{13}O_3NBr_2$, m. 91–2°, heated with NH_4OH or aq. KOH it forms **VIII**. **VII** (1 g.), BzCl (1 g.) and C_6H_6 (10 cc.), refluxed 3–4 hrs., evapd., the residue washed with aq. $NaHCO_3$ and recrystd. from EtOH, yield *benzoyl-3,5-dibromophenetidine*, m. 186–8°. Br (18 g.) in AcOH (30 cc.), added to phenacetin (**IX**) (10 g.) in AcOH (30 cc.) (keeping cold), let stand several hrs., heated 20–30 min. on a water bath, poured into water, and the ppt. purified by recrystn. from EtOH after boiling with animal charcoal, yields *acetyl-2,5-dibromophenetidine* (*2,5-dibromophenacetin*), 3,6,4-$Br_2(AcHN)C_6H_2OEt$ (**X**), m. 170°. **X** can also be prepd. by a method similar to that for 2,5-dichlorophenacetin (cf. *Gazz. chim. ital.* **59**, 16(1929)). A mixt. of Br (13 cc.) and 40% aq. NaOH (20 cc.) (keeping the soln. cool), dild. with water until pptn. is complete, the ppt. purified by crystn. from EtOH after boiling with animal charcoal, yields **X**. According to the conditions of crystn., 2 different forms of **X** are obtained, which m. 169–71° and which can be transformed into one another. From concd. solns. and with rapid cooling, a cryst. needle form is obtained, and from dil. alc. solns. and with slow cooling a rhombohedric form is obtained. **X** (6.5 g.) in AcOH (50 cc.) and concd. HCl (50 cc.), refluxed 4–5 hrs. and cooled, ppts. *2,5-dibromophenetidine-HCl*, m. 225–6°. This, treated with NH_4OH and the product purified by steam distn. and crystn. from dil. EtOH, yields the free *base* (**XI**), m. 55–6°. Satd. alc. picric acid with alc. **XI** forms the *picrate* of **XI**, yellow, m. 143–5°. BzCl (1.5 g.) and **XI** (3 g.) in C_6H_6 (15 cc.), heated 2 hrs. on a water bath, filtered, the residue washed with aq. $NaHCO_3$ and recrystd. from boiling EtOH, yield *benzoyl-2,5-dibromophenetidin*, m. 145–7°. **XI** (2 g.) and **III** (1 g.) in EtOH (20 cc.), refluxed 4–5 hrs., cooled, and the ppt. recrystd. from boiling EtOH, yield *1-ethoxy-2,5-dibromopiperonalaniline*, light yellow, m. 143–5°. **XI** (2 g.), $ClC_6H_3(NO_2)_2$ (1 g.), AcONa (2 g.) and EtOH (20 cc.), refluxed 5–6 hrs., dild. with water, steam-distd., and the resinous residue purified by repeated crystns. from boiling EtOH, give a small yield of *1-ethoxy-2,5-dibromo-2',4'-dinitrodiphenylamine*, brick-red, m. 145–65° (decompn.). **X** (5 g.) and HI (25 cc. of d. 1.7), refluxed 6–7 hrs., poured into water contg. $NaHSO_3$, neutralized with NH_4OH, and the ppt. recrystd. from boiling C_6H_6, yield *2,5-dibromo-4-aminophenol* (**XII**), yellowish, m. 195–7°; its solns. in boiling water and in hot EtOH become rapidly red (decompn.). Concd. $K_2Cr_2O_7$, added to **XII** in cold dil. H_2SO_4, filtered, washed, and the residue steam-distd., yields 2,5-dibromoquinone, m. 185–6° (cf. *Monatsh.* 1, 346(1880); *Ann.* 209, 113(1881)).

C. C. Davis

Preparation of the optically active phenylmethylcarbinols. Armand J. H. Houssa and Joseph Kenyon. *J. Chem. Soc* 1930, 2260–3.—The crystn. of the brucine salt of the H phthalic ester of PhMeCHOH is a convenient method for prepg. the *l*-alc. The *d*-alc. can be obtained only in small amts. by this method, but the H phthalic ester from the mother liquor, on treatment with CS_2, gives a product which, converted into the free *d* + *dl* alc., furnishes a convenient starting point for the prepn. of the *d*-alc. by the succinate method. *l*-PhMeCHOH H phthalate m. 81–2°, $[\alpha]_{5461}^{20}$ 39.8° (EtOH, *c*

5.1220), —59.7° (CS_2, *c* 8.4800), 1.23° ($CHCl_3$, *c* 6.5100); the brucine salt m. 152° (decompn.), $[\alpha]^{17}_{5461}$ —45.7° (Me_2CO, *c* 5.100), $[\alpha]^{18}_{5461}$ —47.7° ($CHCl_3$, *c* 5.085); the free alc., b_{14} 93°, $[\alpha]^{18}_{5461}$ —13.27°, $[\alpha]^{20}_{5893}$ —10.94°, $[\alpha]^{20}_{4358}$ —28.06°; 1.3 mols. *di*-ester gives 0.27 mol. of *l*-alc. of max. activity. C. J. WEST

Mercuration of some polyhydroxybenzaldehydes and their monomethyl ethers. THOMAS A. HENRY AND THOMAS M. SHARP. *J. Chem. Soc.* 1930, 2279–89.—2,4-(HO)$_2$C$_6$H$_3$CHO and 2 mols. Hg(OAc)$_2$ react normally to give the *3,5-diacetoxymercuri deriv.*, faintly pink, does not m. 300°; the *3,5-dichloromercuri deriv.*, needles, decomps. 260°; Br in AcOH converts it into *3,5-dibromoresorcylaldehyde* (I), m. 204° (cor.); I (5% in 10% aq. KI) gives the *3,5-di-I deriv.*, m. 168° (cor.). Methylation of I gives a mixt. of the *2,4-di-MeO deriv.*, m. 101–2° (cor.), the 4-MeO deriv., m. 96–7°, and the 2-MeO deriv., m. 172–4° (cor.). Mercuration of 2,3-, 2,5- and 3,4-(HO)$_2$C$_6$H$_3$CHO is followed by oxidation but the oxidation products could not be isolated. Isovanillin gives a product which was converted into *2-acetoxymercuriisovanillin*, does not m. 300°; the *chloromercuri compd.* m. 255–6°; the bromomercuri compd. is converted by Br in AcOH to *2-bromoisovanillin* (II), m. 211–2°. Bromination of isovanillin gives a mixt. of II and the *6-Br deriv.* (III), whose *monohydrate* m. 112–4° (cor.). II with MeI and MeONa gives *2-bromo-3,4-dimethoxybenzaldehyde*, m. 80° (cor.), sublimes slowly at 70° *in vacuo;* oxidation gives 2,3,4-Br(MeO)$_2$C$_6$H$_2$CO$_2$H, m. 203–4° (cor.), sublimes slowly at 120° *in vacuo*. The structure of III was similarly established, all the products being known. 2,4-HO(MeO)C$_6$H$_3$CHO and Hg(OAc)$_2$ in EtOH contg. a little AcOH give *3-acetoxymercuri-2-hydroxy-4-methoxybenzaldehyde*, m. 159–60° (cor.); the corresponding bromomercuri compd. with Br in AcOH gives *3-bromo-2-hydroxy-4-methoxybenzaldehyde*, m. 119–21° (cor.), sublimes at 100° *in vacuo;* phenylhydrazone, m. 166–7° (cor.); further bromination gives the 3,5-di-Br deriv. 2,5-HO(MeO)C$_6$H$_3$CHO yields a product which was transformed into the *3-chloromercuri deriv.*, m. 242–3° (cor., decompn.), which appears to crystallize in rosettes of yellow flat needles from solns. below 50°, in yellow spherical crystals from solns. above 50° and in hair-like yellow needles when the solns. evap. spontaneously at room temp.; with Br this yields 3,2,5-Br(HO)(MeO)C$_6$H$_2$CHO, m. 110 1° (cor.). *o*-Vanillin yields an acetoxymercuri deriv., which, dried at 100° *in vacuo*, loses its Ac group and gives *2,5-anhydro-5-hydroxymercuri-2-hydroxy-3-methoxybenzaldehyde;* Br gives 5,2,3-Br(HO)(MeO)C$_6$H$_2$CHO, m. 127–9°. The Hg deriv. of vanillin, on treatment with Br, gives 5-bromovanillin, m. 166–9° (cor.). 2,4,6-(HO)$_3$C$_6$H$_2$CHO and Hg(OAc)$_2$ give a compd. contg. 2 atoms Hg, probably $C_7H_4O_5Hg_2$. C. J. WEST

Benzoic esters and electronic affinities of radicals. II. The halogenoalkyl benzoates. AHMAD ZAKI. *J. Chem. Soc.* 1930, 2269–72; cf. *C. A.* 22, 2376.—In Part I comparison was made between the orienting powers of various alkyl radicals as exhibited in the alkyl benzoates; the effect of a halogen in the alkyl group is now considered. The nitration of the esters, the hydrolysis of the products and the subsequent analyses were carried out as in Part I. BzOCH$_2$Cl, b_2 104–6°; nitration gives a 98.2% yield, of which 81.9% is *m*-isomer. BzOCH$_2$CH$_2$Cl, b_{18} 138.8°, b_{762} 255–7°; nitration, 96.9%, 75.8% *m*-isomer. *γ-Chloropropyl benzoate*, b_{15} 155–6° (75% yield); nitration, 98.5%; 77.3% *m*-isomer. BzOCH$_2$CH$_2$Br, b_{15} 147–9°; nitration, 98.7%; 71.5% *m*-isomer. BzOCH$_2$CH$_2$CH$_2$Br, b_{18} 164.5–5.5°; nitration, 99%; 72.8% *m*-isomer. *β-Iodoethyl benzoate*, b_{17} 161–3° (80% yield); on nitration this liberates I. The effect of Cl is greater the nearer the Cl is to the nucleus; the Br esters occupy a place between the corresponding normal and Cl esters and show the alternation exhibited by the other 2 series. C. J. WEST

***p*-Azobenzenesulfonic acid and *p*-mononitro-*p*-azobenzenesulfonic acid.** FRANZ PERKTOLD. *Monatsh.* 56, 247–52(1930).—*p*-HO$_3$SC$_6$H$_4$N$_2$Ph results in 90–100% yield by heating 20 g. PhN$_2$Ph in 120 g. oleum (8–10% SO$_3$) from 90° to 130–5°; prolonging the time of heating does not influence the yield but heating at 140–50° decreases it considerably; the acid crystallizes with 3 mols. H$_2$O; the anhyd. acid has no definite m. p.; the *Na salt* crystallizes with 4 mols. H$_2$O; the Mg and Ca salts are characterized by their insoly.; the *urea salt* was also prepd., as were the *PhNH*$_2$ (1.5 mols. H$_2$O), the *o*- and *p-MeC*$_6$*H*$_4$*NH*$_2$ and *α*- and *β-C*$_{10}$*H*$_7$*NH*$_2$ *salts*. *p*-O$_2$NC$_6$H$_4$N$_2$C$_6$H$_4$SO$_3$H-*p* results by nitration of the above acid at 75°; it crystallizes with 3 mols. H$_2$O; the *urea*, *PhNH*$_2$, *β-C*$_{10}$*H*$_7$*NH*$_2$ and other *salts* were prepd.; with Br in AcOH at 130–50° there appear to be formed a BrC$_6$H$_4$N$_2$C$_6$H$_4$NO$_2$ and a compd., m. 208°, probably 2,6,4-Br$_2$(O$_2$N)C$_6$H$_4$NH$_2$. The soly. of the above salts at approx. room temp. is reported and the probable use of these acids in *anal. chem.* is discussed. C. J. W.

Isomeric monohydroxyphenylalanines. II. Some halogen-substitution products

and their reactions. WM. P. DICKINSON AND PHILIP G. MARSHALL. *J. Chem. Soc.* 1930, 2289–93; cf. *C. A.* **23**, 4684.—The synthesis of dibromo- and diiodo-*o*- and *m*-hydroxyphenylalanines was attempted by the condensation of the appropriately substituted benzaldehydes with glycine anhydride (I) but difficulty was experienced in the purification of the products and in the hydrolysis and reduction the halogen was removed. However, 3.1 g. I, 15.5 g. 3,5,2-$Br_2(HO)C_6H_2CHO$, 10 g. AcONa and 25 g. Ac_2O, heated 12 hrs. at 40°, give 7.9 g. of a mixt., sepd. by crystn. from AcOH in which the *cis*-isomer is very sol., into the *trans*-, decomps. above 300°, and the *cis* form, m. 287°, of *2,5-diketo-3,6-di(3',5'-dibromo-2'-acetoxybenzylidene)piperazine;* reduction with Zn in AcOH gives the *benzyl deriv.*, m. 275°. In the same way the *4'-Ac deriv.* was obtained as pale yellow needles, but no individual product was obtained on reduction. *Bromo-m-hydroxyphenylalanine*, m. 260° (decompn.), was obtained by Zeynek's method (*C. A.* **16**, 1412); the *o-HO deriv.* m. 256°. *Diiodo-m-hydroxyphenylalanine*, m. 230° (decompn.), was prepd. from the acid in NH_4OH (d. 0.880) with 32% I in KI; HCl salt, m. 194°; the *o-HO deriv.* m. 211°; HCl salt, m. 214° (decompn.). *2,5-Diketo-3,6-di-m-acetoxybenzylpiperazine*, m. 191–2°; hydrolysis gives *m*-hydroxyphenylalanine; $FeCl_3$ gives a pale reddish violet color in the cold; all monohydroxyphenylalanines and their halogen derivs. give an orange-yellow to brown color on being warmed with $FeCl_3$. C. J. WEST

Constitution of cetraric acid. GEORG KOLLER AND EHRENFRIED KANDLER. *Monatsh.* **56**, 234–8(1930); cf. *C. A.* **24**, 355.—The same aldehyde is obtained on the degradation of cetraric acid, capraric acid and atranorin and 4,2,6-$Me(HO)_2C_6H_2CHO$. The other possible aldehyde, 3,4,2,6-$Me_2(HO)_2C_6HCHO$, has not been isolated in pure form but its existence has been shown by methylation. C. J. WEST

Constitution of capraric acid. GEORG KOLLER AND WALTER PASSLER. *Monatsh.* **56**, 212–33(1930).—Capraric acid (I) (Hesse and Zopf, *J. prakt. Chem.* **92**, 439(1915)), $C_{24}H_{30}O_{12}$, is a tri-CO_2H acid, contg. a free HO group, 2 Ac groups and a CHO group. The *Ac deriv.* of I is formed by the action of Ac_2O in C_5H_5N. The presence of 3 CO_2H groups is shown by heating I with HI at 150°; the action of MeMgI liberates CH_4 equiv. to 4 HO groups. I and CH_2N_2 give a *compd.* contg. 4 MeO groups, the 2 Ac groups being intact. In the action of Me_2SO_4 on I, the 2 Ac groups are also replaced, giving a *hexa-MeO deriv.* I gives a yellow *phenylhydrazone*, $C_{30}H_{36}O_{11}N_2$, and a yellow *anilide*, $C_{14}H_{13}O_2N$. The action of Zn dust and NaOH in H_2O and a H atom upon I gives an *aldehyde*, $C_8H_8O_3$, m. 122–3, whose *oxime* m. 188° and *anilide* m. 206°; the *di-Me ether* m. 92–3° (*oxime*, m. 215–6°); oxidation of the ether gives 4,3,5-$Me(MeO)_2C_6H_2CO_2H$; therefore, the above aldehyde is 4,3,5-$Me(HO)_2C_6H_2CHO$. The liquid di-Me ether accompanying the ether, m. 93°, is oxidized to *1,2-dimethyl-3,5-dimethoxybenzoic acid*, m. 185° (*Me ester*, m. 40–1°), whose structure was established by the synthesis of *1,2-dimethyl-3,5-dihydroxybenzoic acid*, m. 159–60°, from 1,2,3,5-$Me_2C_6H_2(OH)_2$ and methylation. The mother liquor of the aldehydes contained orcinol. C. J. WEST

Constitution of hydrangenol and phyllodulcinol. III. Synthesis of hydrangenol. YASUHIKO ASAHINA AND JUNTARO ASANO. *Ber.* **63B**, 2059–63(1930); cf. *C. A.* **24**, 3008.—3-Methoxyphthalic anhydride (I), heated with *p*-$MeOC_6H_4CH_2CO_2H$ and NaOAc according to the Gabriel method for prepg. benzalphthalides, gives, in poor yield, *7,4'-dimethoxybenzalphthalide* (II) which dissolves in hot alkali to form $MeO(HO_2C)C_6H_3COCH_2C_6H_4OMe$, easily reduced to $MeO(HO_2C)C_6H_3CH(OH)CH_2C_6H_4OMe$ which on acidification gives *7,4'-dimethoxybenzylphthalide* (III), not identical with the di-Me ether of hydrangenol. When III in KOH in hot MeOH is evapd. to dryness and heated to 200° *in vacuo*, it loses Me and CO_2, yielding methylhydrangeaic acid, 3,2-$HO(HO_2C)C_6H_3CH{:}CHC_6H_4OMe$ (IV), which at 180° forms methylhydrangenol (8-hydroxy-4'-methoxy-3-phenyl-3,4-dihydroisocoumarin) (V). Attempted demethylation of III, IV or V with halogen acids led to formation of tars, but by heating them a long time with alkali *in vacuo* at 230°, taking up in H_2O and acidifying, there was obtained a mixt. of IV and hydrangeaic acid (VI) which on cautious heating at 180° gave a mixt. of the corresponding lactones, hydrangenol (VII) and its Me ether (V). Soln. of the mixt. in hot dil. alkali converts the VII into VI and V into $HO(HO_2C)C_6H_3CH_2CH(OH)C_6H_4OMe$ (VIII), and acids ppt. the VI unchanged while VIII regenerates V, thereby becoming Na_2CO_3-insol. The VI at 180° readily rearranges into VII. 3-Hydroxyphthalic acid was prepd. from the 3-NO_2 compd. according to Bernthsen and Semper and converted with MeI and Ag_2O in Et_2O into $MeOC_6H_3(CO_2Me)_2$, the free acid of which (4 g.) with AcCl and Ac_2O on the H_2O bath gave 3.3 g. I, m. 160°. II (0.07 g. at most from 3 g. I), yellowish, m. 183°, sol. in cold alkalies with deep red

color. **III** (0.75 g. from 1 g. II), m. 108°, sol. in hot alkalies and repptd. unchanged by acids. C. A. R.

Optical activity and the polarity of substituent groups. XVI. Application of the Thorpe-Ingold valency-deflection hypothesis to optically active compounds. H. Gordon Rule and John Harrower. *J. Chem. Soc.* 1930, 2319–28; cf. *C. A.* **24**, 5745.—The influence of *gem*-dialkyl groups, CR_2, on the rotatory power of *l*-menthyl esters of the type $XCR_2CO_2C_{10}H_{19}$ has been examd. The increasing proximity of X and $CO_2C_{10}H_{19}$ resulting from the changes $CH_2 \longrightarrow CMe_2 \longrightarrow CEt_2$ leads to a marked fall in the rotations of the menthyl malonates (X = $CO_2C_{10}H_{19}$), to a rise in the values of the H malonates (X = CO_2H), and to a fall in those of the corresponding Na salts (X = CO_2Na). The depression following the conversion of the acids into their Na salts increases continuously in magnitude from the malonate to the diethylmalonate. These observations are in agreement with the known influence of the substituents X in the *p*- and *o*-substituted benzoic esters, on the assumption that the characteristic *o*-effects are related to the proximity of X to the ester grouping. The MeO esters (X = MeO) exhibit a continuous rise from the methylene to the *gem*-di-Et compd. and thus present no parallel to the characteristic depression occasioned by the MeO group in *l*-menthyl *o*-methoxybenzoate. *l-Menthyl dimethylmalonate*, b_2 210–2°, $d_4^{14.5}$ 0.9712, [*M*] —177.5°, —230.9°, —438.7° for λ = 6708, 5893, 4358 (this order is followed below); data are also given for EtOH and C_6H_6 solns. Partial hydrolysis gives the *H dimethylmalonate*, pale yellow, $d_4^{17.5}$ 1.029, [*M*] —131°, —172°, —342°; data are given for EtOH and C_6H_6 solns. and for the Na salt in EtOH. The *diethylmalonate* m. 52–3°, d_4^{20} 0.9705, [*M*] —181°, —236.2°, —452.3°. The *H diethylmalonate* is a pale yellow, very viscous sirup, d_4^{20} 1.013, [*M*] $_{5461}$ —224.7°. The *α-methoxyisobutyrate* b_{10} 124–6°, d_4^{20} 0.9466, [*M*] —127.9°, —168.1°, —328.2°. The *α-methoxy-α-ethylbutyrate* b_8 139–41°, $[\alpha]^{18}_{5461}$ −76.58°. C. J. West

Organic sulfur-nitrogen unions. Eugen Riesz, A. Lorenz, Ch Myschalow and O Strakosch. *Monatsh.* **56**, 239–46(1930).—This work is a continuation of the study of the oxidation of the S-N union. All of the following compds. gave negative results when treated with 30% H_2O_2 or $Na_2Cr_2O_7$ in AcOH; either the original compd. was recovered or the compd. was more or less completely degraded. *sym-Bis(4-chloro-2-nitrobenzenesulfonyl)benzidide*, m. above 290° (decompn.), from 2 mols each of 4,2-$Cl(O_2N)C_6H_3SO_2Cl$ (I) and (p-$H_2NC_6H_4$)$_2$ in hot Et_2O. p-$H_2NC_6H_4OH$ in hot Et_2O gives *4-chloro-2-nitrobenzenesulfonyl-4'-hydroxyanilide*, m. 92–3°; the *2'-HO deriv.* m. 122–3°. p-$C_6H_4(NH_2)_2$ (2 mols) gives *sym-bis(4-chloro-2-nitrobenzenesulfonyl)-1',4'-diaminobenzene*, m. 250° (decompn.). One mol. I and 2 mols. p-$C_6H_4(NH_2)_2$ give *1'-amino-4'-(4-chloro-2-nitrobenzenesulfenyl)aminobenzene* (II), dark brown, m. 161°; the diazo soln. with β-$C_{10}H_7OH$ gives a dark red dye. Condensation of 2 mols. II with 1 mol. 4,2-$Cl(O_2N)C_6H_4SCl$ in AcOEt gives (*4-chloro-2-nitrobenzoylsulfonyl*)-(*4'-chloro-2'-nitrobenzenesulfenyl*)-*1",4"-diaminobenzene*, m. 164–6° (decompn.). I (2 mols) and 2 mols. o-$C_6H_4(NH_2)_2$ in benzine give *sym-bis(4-chloro-2-nitrobenzenesulfonyl)-1',4'-diaminobenzene*, m. 92–4° (decompn.); using 1 mol. I, there results a *compd.*, yellow-green, m. 143°, which may be *1'-amino-2'-(4-chloro-2-nitrobenzenesulfonyl)-aminobenzene*, although the S values indicate the loss of 1 mol. H_2O. *1'-(Dimethylamino)-4'-(4-chloro-2-nitrobenzenesulfonyl)aminobenzene*, m. 125°. 4,2-$Cl(O_2N)C_6H_4SCl$ and 2 mols. m-$H_2NC_6H_4OH$ in Et_2O give *4-chloro-2-nitrophenylsulfur-3'-hydroxyanilide*, red, m. 158°; with m-$C_6H_4(NMe_2)_2$ there results *1'-(dimethylamino)-3'-(4-chloro-2-nitrophenylsulfur)aminobenzene*, red, m. 148°. C. J. West

Optically active diphenylhydroxyethylamines and isohydrobenzoins. III. Optically active diphenylethylene oxides. John Read and Ishbel Grace Macnaughton Campbell. *J. Chem. Soc.* **1930**, 2377–84; cf. *C. A.* **24**, 609.—In order to decide between the configurations I and II for diphenylhydroxyethylamine (I) and isodiphenyl-

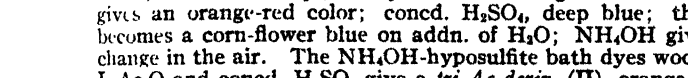
hydroxyethylamine (II), 2,3-diphenylethylene oxide (III) was prepd. from an optically active base of each type, through the corresponding $PhCH(OH)CH(NMe_3OH)Ph$, *dl*- and *l*-II each gave a *cis*-III, m. 42°. *d*-I gave a trimethylammonium iodide, m. 145°, $[\alpha]_D$ 92.4° (MeOH, *c* 1.6290); with Ag_2O there resulted a *l-trans*-III, m. 69–70°, $[\alpha]_D$ 306° (abs. EtOH, *c* 1.3060), —311° (MeOH, *c* 0.5320), —287° (PrOH, *c* 0.5180), —279° (isoPrOH, *c* 0.5110), —249° ($CHCl_3$, *c* 0.5205), —291° (Me_2CO, *c* 0.5655),

—313° (AcOEt, *c* 0.5020), —374° (C_6H_6, *c* 0.4985); some values are given for $[\alpha]_{5461}$. On standing in ordinary abs. EtOH the rotation gradually changed with the formation of *l-isohydrobenzoin Me ether*, m. 45–50°, $[\alpha]_D$ —34.6° (EtOH, *c* 0.5640). A $CHCl_3$ soln. of the *l*-oxide (0.2008 g.) and 1 equiv. of HCl gave $[\alpha]_D$ —233°, which did not change on standing. With 5 and 10 equivs. of HCl there is a change in rotation and the original oxide could not be recovered. *d-trans*-III, prepd. as the *l*-deriv., m. 69–70°, $[\alpha]_D$ 310° (abs. EtOH, *c* 0.5170). *dl-trans*-III also m. 69–70°; the equimol. mixt. of the *d*- and *l*-forms also m. 69–70°, but other mixts. m. less definitely; values are given for 45–100% of the *l*-form. Further study of the oily product of the action of HNO_2 on I or II indicates that the main constituent is a chem. inert and optically inactive product of polymerization contg. C, H and O only. C. J. West

Reducing action of a Grignard reagent. Harold Burton. *J. Chem. Soc.* 1930, 2400.—Benzilamide and *p*-MeC_6H_4MgI in AmOH, heated 8 hrs., give $Ph_2CHCONH_2$ but no *p*-$MeC_6H_4C(OH)Ph_2$. In Et_2O the amide was recovered unchanged after 8 hrs. heating. C. J. West

Organic sulfur compounds. XVII. Sulfur-containing analogs of hexaphenylethane and triphenylmethyl. Alexander Schönberg and Theodor Stolpp. *Ann.* 483, 90–107(1930); cf. *C. A.* 24, 2746.—$Ph_2(PhS)CCl$ and Hg in C_6H_6, shaken for 52 hrs. in the dark, give 57.2% of $Ph_2C{:}CPh_2$ and a larger amt. of $Ph_2C(SPh)_2$, m. 137°. $Ph_2(o\text{-}O_2NC_6H_4S)CCl$ and Hg in C_6H_6 give Ph_2CO, a small amt. of $(o\text{-}O_2NC_6H_4S)_2$ and $(o\text{-}O_2NC_6H_4S)_2CPh_2$. 9-Chloro-9-phenylmercaptofluorene with Hg in C_6H_6 gives *α,β-diphenylmercapto-α,β-dibiphenyleneëthane* (I), m. 220° (decompn.), which gives no halochromism with concd. H_2SO_4; the compd. gives a *mol. compd.* with AcOEt; thermal decompn. of I at about 230° gives a mixt. of $(C_6H_4)_2C{:}C(C_6H_4)_2$ and Ph_2S_2; boiling 2.5 hrs. in BzOEt gives only the hydrocarbon, which is also obtained by the action of light on a C_6H_6 soln. 9-Chloro-9-(*o*-nitrophenylmercapto)fluorene with Hg in C_6H_6 gives *α,β-di-o-nitrophenylmercapto-α,β-bidiphenyleneëthane*, yellow, m. 165–7° (decompn.); the compd. is very sensitive to heat, the decompn. products being fluorenone and a little $(o\text{-}O_2NC_6H_4S)_2$. 9,9-Dichlorofluorene and PhSH in C_6H_6 in CO_2, heated 20 hrs., give the *diphenylmercaptole of fluorenone*, m. 115°, becomes deep red at 220°; the *di-o-nitrophenylmercaptole* (II), yellow-brown, m. 159–60°. Thermal decompn. of II gives fluorenone and a little $(o\text{-}O_2NC_6H_4S)_2$. Thermal decompn. of $Ph_2C(SC_6H_4NO_2)_2$ gives Ph_2CO and $(o\text{-}O_2NC_6H_4S)_2$. $(C_6H_4)_2C(SPh)_2$ at 240° gives Ph_2S_2 and $(C_6H_4)_2C{:}C(C_6H_4)_2$. **XVIII. Thermal rearrangement of thionocarbonic esters into thiolcarbonic esters. 2. Formation of disulfides from phenols.** Alexander Schönberg, L. v. Vargha and Werner Paul. *Ibid* 107–14(1930).—$(p\text{-}MeC_6H_4O)_2CS$, m. 136°, heated 15 min. at 300°, gives *di-p-tolyl thiolcarbonate*, m. 109°; with 4 mols. NaOH in dil. EtOH there results $(p\text{-}MeC_6H_4)_2S_2$, m. 47°. Dithymyl thionocarbonate was prepd. by 2 methods. Thymol (15 g.) in 5% NaOH, treated gradually with 11.5 g. $CSCl_2$, and the resulting $Me_2CHC_6H_3MeOCSCl$ treated with an additional 15 g. thymol, gives 14.5 g. of the ester, m. 85°; 25 g. thymol in C_6H_6, treated with 1 mol $CSCl_2$ and, after a few min. cooking, with 52 g. C_5H_5N, gives 12 g. ester. Heating the ester in N at 300° gives nearly quant. *dithymyl thiolcarbonate*, pale yellow, m. 58–9°; dil. NaOH gives *dithymyl disulfide*, light yellow, m. 63°. *o*-HOC_6H_4Ph (2 mols., 50 g.) in EtOH-KOH and $CSCl_2$ in C_6H_6 give 6.5 g. *di-o-biphenyl thionocarbonate*, pale yellow, m. 106°; rearrangement at 300° and the action of NaOH in EtOH gives a mixt. of *o*-HOC_6H_4Ph and *o*-HSC_6H_4Ph, oxidized by H_2O_2 to *di-o-biphenyl disulfide*, m. 116°. $CS(OPh)_2$ with HgO gives $CO(OPh)_2$. C. J. West

Configurations of the benzil monoximes. Thomas W. J. Taylor and Marcia Sarah Marks. *J. Chem. Soc.* 1930, 2302–7.—The solubilities in C_6H_6 of *α*-benzil oxime from 28.6° to 127–8° and of the *β*-oxime from 33.5° to 103° are reported, from which the nominal heats of soln. are calcd. Analysis of the results indicate clearly that the stereochem. configurations of these oximes are those proposed by Meisenheimer and thus supports the view that, in this case at least, the Beckmann transformation involves the groups in the *anti*-position to one another. Improved methods for the prepn. and purification of these oximes are described. C. J. West

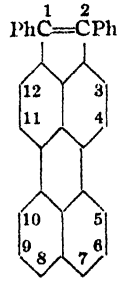


Preparation of 4-nitronaphthalene-1-sulfonyl chloride. W. Brunetti. *J. prakt. Chem.* 128, 44–6(1930).—4,1-$O_2NC_{10}H_6NH_2$, diazotized and poured into satd. H_2SO_3 with stirring (Cu catalyst), gives *4-nitronaphthalene-1-sulfinic acid*, yellow, m. 131°; an alk. soln., treated with Cl, gives 4,1-$O_2NC_{10}H_6SO_2Cl$, m. 99°. C. J. West

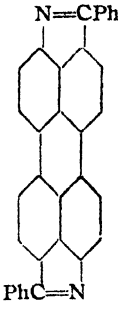
Condensation of aldehyde and phenols. IV. *o*-Chlorobenzaldi-β-naphthol. Otto Dischendorfer. *Monatsh.* 56, 261–71(1930); cf. *C. A.* 22, 3656.—*o*-ClC_6H_4CHO and β-$C_{10}H_7OH$ in AcOH-HCl give *2-chlorobenzaldi-β-naphthol* (I), m. 184–5° (decompn.); *Na salt; diacetate*, m. 198–9°; *dibenzoate*, m. 241–2°; *Me ether*, m. 192–

3°. I in EtOH and NaOH with Br gives the *dehydro deriv.*, bright yellow, m. 258°; cold concd. H_2SO_4 gives a deep yellow color, changing to brown-red on warming. I, heated with AcOH and HCl, gives *meso-2-chlorophenyldinaphthopyran* (II), m. 221°; this also results by adding concd. H_2SO_4 to a mixt. of *o*-ClC_6H_4CHO and β-$C_{10}H_7OH$ in AcOH. II in AcOH, treated with MnO_2 and concd. HCl and heated 15 min., then treated with solid $FeCl_3$, gives *meso-2-chlorophenyldinaphthopyrylium chloride ferrichloride* (III), golden red, m. 215°; the *mercurichloride*, red with green luster, m. 261–2° (decompn.); *perbromide*, dark red, m. 189–91° (decompn.); *perchlorate*, red with green luster, m. 293–4° (decompn.). III with Me_2CO gives *meso-2-chlorophenyldinaphthopyranol*, m. 221°; *Et ether*, m. 236° (slight decompn.); *Me ether*, m. 242° (slight decompn.); *di-NO_2 deriv.*, light yellow, m. 290°. C. J. West

Phytochemistry. VI. Allobetulin. Otto Dischendorfer and Hugo Juvan. *Monatsh.* **56**, 272–81(1930); cf. *C. A.* **23**, 2961.—Apoallobetulin, m. 200–1°, which is obtained from allobetulin and PCl_5 in $CHCl_3$, also results in about 5% yield from betulin with Pd and active C or in 64% yield by treating betulin with fuller's earth in boiling $C_6H_4Me_2$ or in 8% yield by heating without a solvent at 210–60°. Similarly was prepd. *apohydroxyallobetulin*, m. 309°, $[\alpha]_D^{20}$ 79.9° (0.02819 g. in 1.198 g. $CHCl_3$). Allobetulone and *m*-$O_2NC_6H_4CHO$ in AcOH, satd. in the cold with HCl, yield the *m-nitrobenzylidene deriv.*, m. 137–9°. Oxidation of hydroxyallobetulin in AcOH with CrO_3 gives 50% of *hydroxyallobetulone* (I), m. 341–2°, $[\alpha]_D^{20}$ —6.25° (0.03277 g. in 1.3583 g. C_6H_6); *oxime*, m. 333–7° (decompn.); *semicarbazone*, m. 301° (decompn.). Oxidation of I in AcOH with fuming HNO_3 gives hydroxyallobetulinic acid, m. 283–4° (decompn.); the anhydride of this acid yields 30% of a *mono-Br deriv.*, m. 315° (decompn.); this is also obtained by brominating the free acid. C. J. West

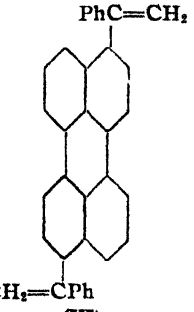


Fungus dyestuffs. IX. Constitution of thelephoric acid. Fritz Kögl, Hanni Erxleben and Ludwig Jänecke. *Ann.* **482**, 105–19(1930); cf. *C. A.* **24**, 3245.—The thelephoric acid (I) was obtained from *Thelephora palmata* by extn. with C_5H_5N in 0.5% yield on the dried material; I is a nearly black powder with a slight metallic luster, without a m. p., nearly insol. in all org. solvents except C_5H_5N; concd. H_2SO_4 gives an orange-red color; concd. H_2SO_4, deep blue; the wine-red soln. in C_5H_5N becomes a corn-flower blue on addn. of H_2O; NH_4OH gives a blue soln.; alk. solns. change in the air. The NH_4OH-hyposulfite bath dyes wool and cotton a violet color. I, Ac_2O and concd. H_2SO_4 give a *tri-Ac deriv* (II), orange-yellow, decomps. 330°; reduction with Zn in AcOH and AcONa gives *pentaacetylleucothelephoric acid*, does not melt. Catalytic reduction of I, followed by methylation with CH_2N_2, gives *heptamethylhexahydrothelephoric acid*, m. 246°; the mother liquor gives a yellow compd., m. 237°, and also a colorless compd. Zn distn. of II gives *7-phenanthryl-1*(or *2?*)*butadiene*, $C_{18}H_{14}$, m. 125°, oxidized by $KMnO_4$ to phenanthrene-2-carboxylic acid, m. 254°. Oxidation of I with H_2O_2 in 0.1 *N* NaOH gives *1-hydroxybenzene-2,4,5-tricarboxylic acid* (III), m. 241° (decompn.), which was synthesized from pseudocumenesulfonic acid. Oxidation of the hexahydro deriv. of I with H_2O_2 gives the same acid and also adipic acid. Oxidation of I with CrO_3 gives III and a *trihydroxybiphenyltetracarboxylic acid*, m. 290°; decarboxylation of this acid gives *4,3',6'-trihydroxybiphenyl* (IV), m. 234°, oxidized by H_2O_2 to *p*-$HOC_6H_4CO_2H$. *p-Methoxyphenylquinone*, m. 110°, on reduction and demethylation, gives IV. These facts lead to the formula



for I. C. J. West

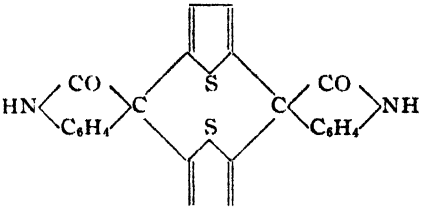
Perylene and its derivatives. XXIX. Degradation of perylene to benzanthrone. Alois Zinke and Rudolf Wenger. *Monatsh.* **56**, 143–52(1930); cf. *C. A.* **24**, 2126.—In the oxidation of perylene with CrO_3 in H_2O (heating 6 hrs.) there results, in addn. to perylene-3,10-quinone and anthraquinone-1,5-dicarboxylic acid, a small amt. of *1,9-benz-2-anthrone-5,10-dicarboxylic anhydride* (I), brown needles, which is extd. by 4% aq. NaOH and pptd. by HCl; it may be crystd. from $PhNO_2$ or sublimed *in vacuo* in a CO_2 stream. The concd. H_2SO_4 soln. of I is a bright golden brown with a yellow fluoresence; the hyposulfite bath is at first violet, then changes to a wine-red and a dark brown, which becomes a bright yellow-brown on boiling and shows a strong green fluorescence. I also results from the quinone in concd. H_2SO_4 and MnO_2. The Na salt from I, pptd. with ice-cold HCl, gives the free *acid* (II), light yellow; crystn. from $PhNO_2$ gives I; *Ca salt*, ocher-yellow; NH_4OH gives the *imide*, brown-yellow, sol. in concd. H_2SO_4 with a gold-brown color and a pale yellow fluorescence; NaOH gives a yellow-brown color without fluorescence; the hyposulfite bath is blood-red and then violet; *di-Me ester*, from the Ag salt and MeI, yellow, m. 190–1°. I and Br in $PhNO_2$



give a *di-Br deriv.*, light yellow, which gives I on crystn. from $PhNO_2$; similarly, II gives a *di-Br deriv.*, light yellow. Zn distn. of I gives benzanthrene, identified as its oxidation products. **XXX.** A. ZINKE AND OTTO BEBBDORF. *Ibid* 153–62.—Perylene and BzCl with $AlCl_3$, after 20–4 hrs. at room temp., give a mixt. of the *3,9*-(I) and *3,4-di-Bz derivs.* (II), sepd. by extg. the first with $C_6H_4Me_2$; the residue crystd. from $PhNO_2$ gives II, yellow to brown-red, m. 329–30°, sol. in 1000 parts boiling AcOH and 300 parts boiling $C_6H_4Me_2$, easily sol. in $PhNO_2$; concd. H_2SO_4 gives a green soln. with a strong, fiery blood-red fluorescence. Reduction of II with amalgamated Zn and concd. HCl gives *1,2-diphenylaceperylene* (III), dark brown-red with violet luster, m. 315–

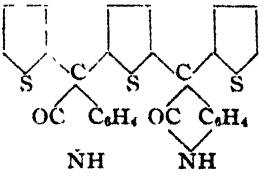
(III)

(IV)



(VI)

6°. II and Br in AcOH give the *compd.* $C_{34}H_{19}O_2Br$, yellow, m. about 326–30°. I with KNO_2 and H_2SO_4 in AcOH gives the *4,10-di-NO_2 deriv.*, red needles; reduction with hyposulfite gives the *compd.* $C_{34}H_{18}N_2$ (IV), dark green needles with violet-blue luster; concd. H_2SO_4 gives a deep blue color, as does AcOH; Br gives a *tetra-Br deriv.*, blue. II also gives a *di-NO_2 deriv.*, red needles from $PhNO_2$, brown leaflets from $C_6H_4Me_2$. II and MeMgI give the *tert. alc.* $C_{36}H_{28}O_2$ (V), light yellow, m. 277°; heating with AcOH gives the hydrocarbon $C_{36}H_{24}$ (VI), yellow, m. 257–8°. Diacetylperylene yields a *di-NO_2 deriv.*, $C_{24}H_{14}N_2O_6$, red needles, giving a deep green soln. in concd. H_2SO_4. (WITH H. KOLMAYR.) Perylene and chloroacetyl chloride give with $AlCl_3$ in CS_2 a *di-(chloroacetyl)perylene*, brown needles with a green metallic luster, giving a blue soln. in concd. H_2SO_4, which shows a red fluorescence on heating, the soln. turning greenish blue. **XXXI.** ALFRED PONGRATZ AND ANDRIJ HALABARDA. *Ibid* 163–78.—Perylene and *m*-MeC_6H_4COCl with $AlCl_3$ give *di-m-toluylperylene*, yellow, m. 248–50°, sol. in concd. H_2SO_4 with a violet-blue color; the *p-isomer*, yellow-brown, m. 340–1°; concd. H_2SO_4 gives a bluish green soln. with red fluorescence; the same compd. is obtained with or without CS_2. Perylene-3,9-dicarbonyl chloride (I) and *o*-$C_6H_4Me_2$ with $AlCl_3$ give *3,9-di-o-toluylperylene*, orange-yellow, m. 270–3°, sol. in concd. H_2SO_4 with a violet-blue color; the *m-isomer*, yellow, m. 262–4°; the *p-isomer*, brownish red, m. 247–9°. I and anthracene give the compd. $C_{50}H_{28}O_2$, orange-yellow, does not m. 360°; concd H_2SO_4 gives a violet-blue color; phenanthrene gives the *compd.* $C_{50}H_{28}O_2$, yellow, does not m. 360° and gives a greenish blue soln. in concd. H_2SO_4. I and $PhNH_2$, gently warmed, give the *dianilide* (II), light yellow, giving an orange color in concd. H_2SO_4; the *di-o-chlororanilide* (III), yellow, m. 342–5°; I and PhNHMe give the *compd.* $C_{36}H_{26}O_2N_2$, yellow, m. 270–2°, and gives a yellow-brown soln. in concd. H_2SO_4; it is unchanged by PbO_2 in boiling $PhNO_2$. PbO_2 and II, boiled 1 hr. in $PhNO_2$, give the *compd.* $C_{34}H_{20}O_2N_2$, brown-red needles; similarly III gives a *compd.*, red needles. I and β-aminoanthraquinone in $PhNO_2$ at 180–90° give the *compd.* $C_{50}H_{26}O_6N_2$, brown-red needles. I is not brominated by Br or at least the product on recrystn. from BzCl is unchanged I. Perylene-3,9-dicarboxylic acid (1 g.) and 1 g. Br at room temp. give the *mono-Br deriv.*, yellow needles, does not m. 360°; this also results with Br in $PhNO_2$; in concd. H_2SO_4 there results a *tetra-Br deriv.*, yellow needles; the *di-Et ester* from I, m. 275–6°, gives a *di-Br deriv.*, yellow, m. 248–50°; heating with $PhNH_2$ splits off the Br, giving the free ester. Heating the acid, CuCN and quinoline 1 hr. gives perylene.



C. J. WEST

Thiophene series. XXI. Indophenin. WILHELM STEINKOPF AND JOHANNES ROCH. *Ann.* **482**, 251–64(1930); cf. *C. A.* **20**, 2854.—This study was undertaken to det. if possible the structure of indophenin (I). The Grignard reagent from bromothiophene with $CuCl_2$ in abs. Et_2O gives 44% of dithienyl (II), m. 33°; 2,5-dibromo-

thiophene gives 38% of *5,5'-dibromo-2,2'-dithienyl*, m. 143°. 2-Bromo-5-methylthiophene gives 12% of *5,5'-dimethyl-2,2'-dithienyl*, m. 67°. II (5 g.) in 500 cc. C_6H_6 and 5 g. isatin in 100 cc. concd. H_2SO_4, shaken 2 min. at 0–3° and then poured into 3 l. H_2O, give 4 g. *bis(α-ketodihydro-β-indolidene)tris(α-dithienyl)* (III), olive-green, with no m. p., difficultly sol. in $C_6H_4Me_2$, quinoline, tetralin, C_5H_5N and PhOH; concd. H_2SO_4 gives a blue soln., from which H_2O ppts. a violet-blue compd., sol. in NH_4OH. III also results by heating the 2 compds. with $ZnCl_2$ 2 hrs. at 100°. *p-Nitrobenzoyl deriv.*, dark green; *p-bromobenzoyl compd.* II and bromoisatin in concd. H_2SO_4 at 0° give *cyclic bis(α-ketodihydro-β-bromoindolidene)bis(α-dithienyl)*, blue amorphous product; with $ZnCl_2$ at 100° there results *bis(α-ketodihydro-β-bromoindolidene)tris(α-dithienyl)*, olive-green. Thiophene (2.1 g.) and 3.7 g. isatin, heated with 5 g. $ZnCl_2$ 2 hrs. at 100°, give 1.2 g. of a product resembling indophenin in its reactions; with alk. hyposulfite there results a red-brown bath with an intense green fluorescence; warming at 60° for 10 min. and filtering gives (after repeating the operation 6 times) 40–50% of an insol. *compd.*, $C_{28}H_{18}O_2N_2S_3$, olive-green, has no m. p., which may have the structure IV. Consideration of the structure of I leads to the following:

(I)

(IV)

C. J. West

N-**Substituted oxindoles and isatins.** R. Stollé, R. Bergdoll, M. Luther, A Auerhahn and W. Wacker. *J. prakt. Chem.* **128**, 1–43(1930).—$PhNHCOCH_2Cl$ and $AlCl_3$ give 85% of oxindole, m. 127°. *o*-$MeC_6H_4NHCOCH_2Cl$ and $AlCl_3$, heated 1.5 hrs. at 225–30°, give *7-methyloxindole*, m. 200°; the 5-Me deriv. m. 168°. *m*-$C_6H_4(NH_2)_2$ and $(ClCH_2CO)_2O$ in Et_2O give *bis(chloroacetyl)-m-phenylenediamine*, m. 212°; this could not be condensed with $AlCl_3$ to an oxindole ring. *Bromoacetyl-β-naphthylamine*, m. 134°. *Chloroacetyl-α-aminoanthraquinone*, yellow, m. 218°; *trichloroacetyl deriv.*, yellow, m. 234°. None of these derivs. could be condensed by $AlCl_3$. $PhNMeCOCH_2Cl$ and $AlCl_3$ at 180° give 1-methyloxindole, m. 88°; HNO_2 gives the *3-isonitroso deriv.*, yellow, m. 189°; BzH gives the *3-benzylidene deriv.*, m. 71°; Br and KBr give the *5-Br deriv.*, m. 133° (*oxime*, yellow, m. 225°; *3-p-dimethylaminobenzylidene deriv.*, red, m. 212°); bromination in hot H_2O gives the *5,7-Br_2 deriv.*, m. 200° (*3 dimethylaminobenzylidene deriv.*, dark red, m. 208°; *3,3-Cl_2 deriv.*, m. 182°, by the action of $CO(OCl)_2$ in EtOH). 1-Methyl-3,3-dichlorooxindole, m. 149°; *5-Br deriv.*, m. 155°. 1-Ethyloxindole (I) and $NOC_6H_4NMe_2$ with EtONa in EtOH give *1-ethyl-3-p dimethylaminoanilisatin*, dark brownish gray with green luster, m. 170°; hot EtOH-HCl gives quant. 1-ethylisatin. I and Br in ice-cold CCl_4 give a *di-Br addn. product*, m. 74° after washing with Et_2O; on warming the CCl_4 soln., there results the 3,3-di-Br deriv., light yellow, m. 95°; Br-H_2O with I in CCl_4 gives the *5-Br deriv.* (II), m. 108°; with $NOC_6H_4NMe_2$ there results *1-ethyl-5-bromo-3-p-dimethylaminoanilisatin*, dark red, m. 174°. I and 3 mols. Br in CCl_4, on standing 14 days at room temp., give the *3,3,5-tri-Br deriv.*, pale yellow, m. 144°. 1-Phenyloxindole (III), heated with *N* NaOH for 2 hrs., gives *o-anilinophenylacetic acid*, m. 114°. III in CCl_4, shaken with Br-H_2O, gives the *5-Br deriv.*, m. 162°; with $ONC_6H_4NMe_2$ there results *1-phenyl-3 bromo-3-p-dimethylaminoanilisatin*, dark red with green luster, m. 180°. The *5,5-Br_2 deriv.* of III, pale yellow, m. 162° (decompn.). III and Br in boiling CCl_4 give the *3,3-Br_2 deriv.* (IV), yellow, m. 131°; boiling with 1 equiv. of III in CCl_4 for 10 hrs. gives the *3-Br deriv.*, pale yellow, m. 98°; heating at 280° gives 1,1'-diphenylisoindigotin. Heating IV with 1 mol. Br in CCl_4 for 4 hrs. (Fe as catalyst) gives the *3,3,5-tri-Br deriv.*, m. 168°. III and 4 mols. Br in CCl_4, boiled 20 hrs., give *3,3,5,7-tetra-Br deriv.*, m. 172°. *Dichloroacetyldiphenylamine*, m. 79°; *dichloroacetylmethylanilide*, m. 69°; these could not be condensed to oxindole derivs. by $AlCl_3$. *Trichloroacetyldiphenylamine*, m. 86°, with $AlCl_3$ in CS_2 gives the 3,3-Cl_2 deriv. of III, m. 117°; it also results from III and $Ca(OCl)_2$. PhNHMe and $(COCl)_2$ in Et_2O give *N-methyloxanilyl chlo-*

ride, PhNMeCOCOCl, m. 30°; the *anilide* m. 105°; the chloride and ... give 1-methylisatin (V), m. 135°; it also results from 1-methyl-3,3-dichlorooxindole (VI) by heating with EtOH-H_2O NaOH. The 1-Br deriv. of V, m. 170°, results in the same way from the 5-Br deriv. of VI, while the 5,7-Br_2 deriv. gives 1-methyl-5,7-dibromoisatin, m. 175°. *Diethyloxanilide*, m. 93°. *Ethyloxanilide*, m. 116°. 1-Ethyl-5-bromoisatin, m. 145°, results from 1-ethyl-5-bromo-3-*p*-dimethylaminoanilisatin and concd. HCl or from 1-ethyl-3,3,5-tribromooxindole with EtOH-NaOH. *Diphenyloxanilyl chloride*, m. 70°; cooking with H_2O gives *diphenyloxamidic acid*, m. 146°. 1-Phenylisatin (VII), m. 138°, is formed, among other ways, from *1-phenyl-3-p-dimethylaminoanilisatin*, dark brownish gray, m. 174°, and EtOH-HCl; *oxime*, light yellow, m. 221°. VII and warm NaOH give *Na pl* ... The *5-Br deriv.* ... with *N* NaOH ... *Na 1-* ... 156°

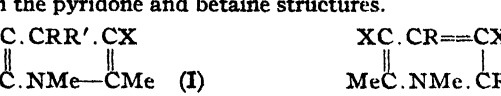
$AlCl_3$ in CS_2 gives *1-phenyl-3,...* ... rk red, m. 214°; in 1 case there resulted *1-α-naphthylisatin*, reddish yellow, m. 176°. *Phenyl-β-naphthylaminooxalyl chloride* (IX), turns deep red at 100° and m. about 225°; the free acid m. 221°; *Et ester*, m. 103°; *anilide*, m. 219°. Warming VIII with alk. H_2O_2 gives *1-phenylaminonaphthalene-2-carboxylic acid*, m. 236°. Na 1-phenyl-4,5-benzoisatinate and H_2O give the isomeric *2-phenylaminonaphthalene-1-carboxylic acid*, reddish brown, m. 146° (decompn.). IX, heated 1 hr. at 130°, gives 1-phenyl-5,4-benzoisatin, m. 229°; this does not show the indophenin reaction. $(\beta\text{-}C_{10}H_7)_2NH$ and $(COCl)_2$ give *di-β-naphthylaminooxalyl chloride*, rose, m. about 266°; the free *acid* m. 169° (decompn.); *Me ester*, m. 141°. *Et ester*, m. 110°; *amide*, m. ...

3-hydr ... dark ... red, m. ... *droxyisoindigotin*, m. 172°; warming with concd. H_2SO_4 or boiling with ... diphenylisoindigotin, m. 314°; warming with AcOH and concd. HNO_3 gives phenylanthranilic acid, m. 182°. The 5-Br deriv. of III and *p*-$ONC_6H_4NMe_2$ in boiling AcOH give *1,1'-diphenyl-5,5'-dibromoisoindigotin*, dark red-violet, does not m. 360°. VII and β-hydroxythionaphthene in EtOH-Na_2CO_3 give *3-(phenylindole)-2'-(thio* ... (C_6H_5CO)$_2O$ heated at 200°, give

gives the *acid*, $C_{22}H_{15}O_4N$, yellow, ... Na 1-phenylisatinate at ... gives the Na salt of 9-acridylcarboxylic acid, m. 295°. In the formation of the 5-Br deriv. of VII there is also formed a small amt. of *7-bromoacridine-9-carboxylic acid*, yellow, m. 278°. 2,7-Dimethylacridine results as a by-product of the action of $(COCl)_2$ on $(p\text{-}MeC_6H_4)_2NH$. VIII, warmed with NaOH, gives 5,6-benzacridine-9-carboxylic acid, m. 286°; heating at 300° gives 5,6-benzacridine, m. 108°. 1-Phenyl-4,5-benzisatin and NaOH give *7,8-benzacridine-9-carboxylic acid*, yellow, m. 276° (decompn.); heating at 280° gives 7,8-benzacridine, m. 131°. 1,2,7,8-Dibenzacridine-9-carboxylic acid, m. 232°, results from 1-β-naphthyl-4,5-benzoisatin; *Na salt*, pale yellow needles.

C. J. West

Reactivity of positivized hydrogen atoms. IV. Oxido-oxazoles. W. Dilthey and J. Friedrichsen. *J. prakt. Chem.* 127, 292–306(1930); cf. *C. A.* 23, 5176.—The following *4,5-dimethyloxidooxazoles* were obtained by condensation of AcC(:NOH)Me with the proper aldehyde in AcOH-HCl: 2-Ph, m. 103–4°; tetrahydrate, m. about 60°; HCl salt, m. 188° (cf. Diels and Riley, *C. A.* 9, 2250). *2-(4-methoxyphenyl)*, m. 141°; *dihydrate*, m. 80°. *2-(2-Hydroxyphenyl)*, m. 105–6°. *2-(3,4-Methylenedioxyphenyl)*, m. 175–6°. *2-(3-Nitrophenyl)*, yellow, m. 159–60° (decompn.); the *4-NO_2 isomer*, yellow, m. 199–200°. *2-Styryl*, m. 131°; HCl salt, m. 185°. *2-(2,4-Dihydroxyphenyl)*, m. 225–6°. Benzoylacetyl 2-monoxime and BzH give *2,5-diphenyl-4-methyloxidooxazole*, m. 153°, crystals with 1 mol. H_2O; the HCl salt m. 180–5°; *p*-$MeOC_6H_4CHO$ gives the *2-(4-methoxyphenyl) deriv.* (I), m. 156–7°, crystg. with 3 mols. H_2O; *o*-HOC_6H_4CHO gives the *2-(2-hydroxyphenyl) deriv.*, yellow, m. 130–1°;



piperonal gives the *2-(3,4-methylenedioxyphenyl) deriv.*, m. 168–70°; the *3-*, *2-* and *4-nitrophenyl derivs.* are yellow and m. 176–7° (decompn.), 157–8° and 188–9°, resp. BzH and α-BzC(:NOH)Ph in AcOH-HCl give *2,4,5-triphenyloxidooxazole* (II), m. 170–1°, crystals with 3 mols. H_2O; β-BzC(:NOH)Ph gives the same product. *p*-$MeOC_6H_4CHO$ gives *2-(4-methoxyphenyl)-4,5-diphenyloxidooxazole*, m. 194–5° (60% yield); *2-(3-nitrophenyl) deriv.*, yellow, m. 178–9° (60% yield). Reduction of I with Zn and AcOH gives *2-(4-methoxyphenyl)-4-methyl-5-phenyloxazole*, m. 77–8°. II gives 2,4,5-triphenyloxazole, m. 114–5°. The mechanism of these condensations is discussed.
C. J. West

1,3,4-Triazoles. Kashmiri Lal Bhagat and Jnanendra Nath Ray. *J. Chem. Soc.* **1930**, 2357–8.—$BzNHNHCOCH_2Ph$ and $PhNH_2$, heated with $ZnCl_2$ at 180–90° for 3 hrs., give *1,2-diphenyl-5-benzyl-1,3,4-triazole*, m. 200°; similarly *m*-$MeC_6H_4NH_2$ and *p*-$MeOC_6H_4NH_2$ give, resp., the *2-phenyl-1-m-tolyl deriv.*, m. 240°, and the *2-phenyl-1-p-methoxy deriv.*, m. 225°. $(NHBz)_2$ and *p*-$MeC_6H_4NH_2$ give *2,5-diphenyl-1-p-tolyl-1,3,4-triazole*, m. 296–7°, and a *compd.*, m. 115°, which has not been identified. Similarly, *p*-$MeOC_6H_4NH_2$, *m*-$MeC_6H_4NH_2$ and *p*-$EtOC_6H_4NH_2$ give, resp., the *1-p-MeO deriv.*, m. 246–7°, the *1-m-tolyl deriv.*, m. 250°, and the *1-p-EtO deriv.*, m. 215°. BzNHNHAc and $PhNH_2$ give PhNHBz. These triazoles are rather weak bases and do not form stable salts with acids. The pharmacol. properties will be published elsewhere.
C. J. West

Diphenylene oxide series. II. Nicholas M. Cullinane. *J. Chem. Soc.* **1930**, 2267–9; cf. *C. A.* **18**, 1655.—Nitration of diphenylene oxide gives 80% of the $2\text{-}NO_2$ deriv., m. 182°, since on reduction the $2\text{-}NH_2$ deriv. (90% yield, m. 94°) yields, through the Sandmeyer reaction, a *2-Cl deriv.* (I), m. 104°, identical with the product obtained as follows: *5-Chloro-2-aminodiphenyl ether*, gray, m. 44°, obtained by reduction of the NO_2 deriv., yields a diazo compd., which, heated with 50% H_2SO_4, yields I. The isomer, m. 110°, formed in small quantities in the nitration, must be the $1\text{-}NO_2$ deriv.
C. J. West

Dihydropyridine derivatives and pyridones. K. v. Auwers (with W. Susemihl and E. Wolter). *Ber.* **63B**, 2111–9(1930).—In the course of his investigations of pyridone methides and dipyridyls Mumm prepd., among other compds., a series of dihydropyridine derivs., part of which, according to M., have the structure I, others the structure II (R and R′ = H, alkyl or aryl, X = CO_2Et), while the structure of still others was left an open question. As the 2 groups of substances should differ distinctly from each other in their spectrochem. behavior it seemed possible that the structure of these compds. might be established optically. Some of the compds. could not be used because they were too deeply colored, and for the same reason the dispersion of most of them could not be detd., as the Hβ and Hγ lines could not be read. However, the data obtained suffice for the drawing of certain conclusions. Below are given, resp., the temp. (t°) and the values for EΣ for α, D, β-α, at t° and for D at 20°. Di-Et *sym-N*-methyldihydrocollidinedicarboxylate (I), 99.5°, 1.79, 1.95, 128%, 1.65. Di-Et *sym-N*-methyl-γ-isobutyldihydro-α,α′-lutidinedicarboxylate (I), 99.8°, 1.41, 1.54, 102%, 1.25. Di-Et *asym-N*-methyldihydrocollidinedicarboxylate (II), 18.9°, 1.98, 2.25, ——, 2.25. Di-Et *asym-N*-methyl-γ-ethyldihydro-α,α′-lutidinedicarboxylate (II), 66.0°, 2.20, 2.49, ——, 2.3. γ-Iso-Bu homolog (II), 18.2°, 1.82, 2.08, ——, 2.1. Di-Et *N*-methyl-2,4,4,6- or 2,2,4,6-tetramethyldihydropyridine-3,5-dicarboxylate, 66.9°, 0.92, 1.06, ——, 0.9. Di-Et *N*-methyl-2,3,6-trimethyl-4- or 2-phenyldihydropyridine-3,5-dicarboxylate, 100.0°, 1.00, 1.25, ——, 0.95. As was expected, both groups show powerful exaltations. It was also to be expected that the unsym. compds. with their accumulated (*gehäufte*) conjugation C:C.C:C.C:O would show stronger exaltations than the sym. compds. with the simple conjugation C:C.C:O, even though the latter occurs twice in the mol. The above values show beyond doubt that the last 2 compds. are sym. dihydro derivs. For 2 pyridones were found the values: *N*-methyl-4,6-dimethyl-3-acetyl-5-carbethoxy-α-pyridone, 100.6°, 1.34, 1.43, 87%, 1.15; *N*-methyl-6-methyl-4-isobutyl-3-acetyl-5-carbethoxy-α-pyridone, 100.0°, 1.00, 1.25, ——, 0.95. In view of the new conjugation in these compds., the results were surprisingly low. There is a difference of opinion, however, as to the structure of these compds.; in addn. to the hydroxy and keto forms, betaine-like formulas have also been suggested for these compds. and their *N*-alkyl derivs. It therefore became necessary to investigate spectrochemically a few simple pyridones and derivs. In the following list, the first 4 compds. are certainly *O*-ethers of hydroxypyridines, and for the 5th, β-hydroxypyridine, there is no possibility of a tautomeric form; for α-hydroxypyridine the exaltations are calcd. for both the keto and the enol form; the last 2 compds. are certainly *N*-alkyl derivs. The values given are, resp., for t°, EΣ for α, D, β-α, γ-α,

at t°, and for D at 20°. α-Ethoxypyridine, 16.3, —0.49, —0.50, 12%, 13%, —0.5; β-isomer, 18.0°, —0.41, —0.42, 16%, ——, —0.4; γ-MeO compd., 22.2°, —0.74, —0.76, 7%, 7%, —0.75; γ-PhO compd., 67.3°, 0.03, 0.02, 12%, 15%, —0.15; β-HO compd., 16.9°, —0.69, —0.68, 22%, ——, —0.7 (in quinoline); α-HO compd. 99.6°, 0.28, 0.36, 50%, ——, 0.05 for enol form, 99.6°, 1.21, 1.32, 55%, ——, 1.0 for enol form (in $C_{10}H_7Me$); *N*-ethyl-α-pyridone, 19.8°, 0.54, 0.64, 56%, ——, 0.65; *N*-methyl-γ-pyridone, 21.6°, 0.68, 0.77, 37%, 40%, 0.75 (in quinoline). The consts. of the *O*-ethers, as expected, show a weakening by the substituents of the strong depression characteristic of C_5H_5N. The generally accepted view that β-hydroxypyridine is a true HO compd. is confirmed. On the other hand, the α-isomer cannot be a phenol; its consts. show that its structure corresponds rather to that of the *N*-alkylpyridones. The fact that these simple pyridones show the same low exaltations as the more complicated derivs. mentioned above indicates that this is a general property of such compds. It appears less striking when it is considered that conjugated systems whose double bonds lie entirely or partly in a ring regularly produce lower exaltations than in open-chain compds. Thus, α-pyrone gives 20.7°, 0.97, 1.05, 71%, 84%, 1.05, and γ-pyrone 66.6°, 0.95, 1.00, 43%, 47%, 0.85. Even so, it is a question whether the low exaltations of the pyridones are actually the result only of their ring structure. It would be desirable to test their spectrochem. behavior on the basis of a betaine structure, but this cannot be done with any certainty as the at. refractions of O and N in such compds. is not known. The same is true of intermediate (*Zwitter*) ion formulas, representing a condition between the pyridone and betaine structures.

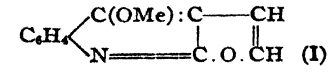
C. A. R.

Derivatives of 4-methyl-, 4,6-, 4,7- and 4,8-dimethyl-2-hydroxyquinolines. Isidore E. Balaban. *J. Chem. Soc.* **1930**, 2346–54.—Starting with certain 2-hydroxyquinolines, aminotetrahydroquinolines were prepd. for biol. examn. in malaria. Nitration of 2-hydroxy-4-methylquinoline in concd. H_2SO_4 at room temp. gives quant. the *6-NO_2 deriv.* (I), m. 340° (decompn.); this was also obtained from *p*-$O_2NC_6H_4NHCOCH_2Ac$ and concd. H_2SO_4. Oxidation of I with $KMnO_4$ gives 5-nitrobenzoxazolone, m. 242°. Refluxing I with PCl_5 and $POCl_3$ for 1 hr. at 160° gives the *2-Cl deriv.*, pale brown, m. 207°. Reduction of I with $SnCl_2$ and concd. HCl gives 63.5% of the *6-NH_2 deriv.*, pale yellow, m. 315°; *HCl salt*, needles, do not m. 310°; *Ac deriv.*, m. 314°. *2-Hydroxy-4-methylquinoline-6-arsonic acid*, in 18% yield from the NH_2 deriv. by the Bart-Schmidt reaction, crystals with 1 mol. H_2O; the Mg, Ca and Ba salts are cryst. 2-Hydroxy-4,6-dimethylquinoline gave the following derivs.: *3-NO_2 deriv.*, m. 294°; *2-Cl deriv.*, yellow, m. 157°; *3-NH_2 deriv.*, m. 264° (*HCl salt*, yellow, m. 240°; *Ac deriv.*, m. 270°). Derivs. of 2-hydroxy-4,7-dimethylquinoline: *6-NO_2 deriv.*, darkens about 280° with partial decompn., sparingly sol. in AcOH; oxidation gives 5-nitro-4-methylbenzoxazolone, m. 233°; *2-Cl deriv.*, m. 164°; *6-NH_2 deriv.*, blackens at 320° (45% yield); *HCl salt*, does not m. 320°; *Ac deriv.*, does not m. 320°; *6-arsonic acid*, boat-shaped needles, not melted at 320° (4.1% yield); the Mg, Ca and Ba salts are cryst. The *8-NO_2 deriv.*, yellow, m. 226° (oxidation gives *3-nitro-4-methylbenzoxazolone*, brown, m. 236°); *2-Cl deriv.*, m. 156°; *8-NH_2 deriv.*, m. 255°; *HCl salt*, crystg. with 1 mol. H_2O, m. 257° (decompn.); *Ac deriv.*, crystals with 2 mols. H_2O, m. 266°. Derivs. of 2-hydroxy-4,8-dimethylquinoline: *6-NO_2 deriv.*, m. 310° (decompn.) (81% yield); (oxidation gives *5-nitro-3-methylbenzoxazolone*, pale yellow, m. 249°); *2-Cl deriv.*, pale yellow, m. 195°; *6-NH_2 deriv.*, pale yellow, m. 288° (54.4% yield), *HCl salt*, yellow, does not m. 320°; *Ac deriv.*, plates, do not m. 320°; *6-arsonic acid*, crystals with 0.25 mol. H_2O (9.6% yield); the Mg and Ba salts are cryst. Oxidation of 2-hydroxy-4-methylquinoline gives benzoxazolone, crystals with 1 mol. H_2O, m 142°. Tests are reported for the arsonic acids on mice infected with *T. equiperdum*

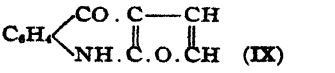
C. J. West

Comparison of the directive powers of elements having consecutive atomic numbers. II. Mononitrations of 2-phenylquinoline and its methosulfate. Raymond J. W. Le Fèvre and Faqir Chand Mathur. *J. Chem. Soc.* **1930**, 2236–41; cf. *C. A.* **24**, 1378.—*2-Phenylquinoline methosulfate* (I), m. 142–3.5°, in 85% yield from 2-phenylquinoline (II) and Me_2SO_4 by boiling 2 hrs.; *methopicrate* (III), yellow, m. 138–9°. Nitration of I at 0° gives 97% of the *m*-NO_2 deriv. of III, m. 181–2°; boiling with concd. HCl gives the *methochloride*, whose hydrated form m. 52°, gives off H_2O at 120–30° and then m. 204–5°; heating at the m. p. for 0.5 hr. gives 2-*m*-nitrophenylquinoline.



m. 123–4°. Nitration of II gives about 60% of the *p*-NO_2 deriv., light yellow, m. 129–31°, and about 30% of the *m*-NO_2 deriv. The *p*-NO_2 deriv. was synthesized from *p*-$O_2NC_6H_3CH{:}CHCHO$, $PhNH_2$ and concd. HCl; the *o-NO₂ deriv.*, m. 121–3°, was similarly synthesized. Attempts to synthesize 4-phenylquinoline failed. C. J. W.

Action of lithium alkyls upon acridine and several other alkali organic reactions in the acridine series. Ernst Bergmann, Ottilie Blum-Bergmann and Alfred Freiherr von Christiani. *Ann.* **483**, 80–9(1930).—Acridine and the Li deriv. of PhBr give 9,10-dihydro-9-phenylacridine, m. 170°; *p*-$MeOC_6H_4Br$ gives the *9-p-anisyl deriv.*, m. 183–4°; *o*-MeC_6H_4Br gives the *9-o-tolyl deriv.*, m. 185–6°; the *m-isomer* m. 148–9°; α-$C_{10}H_7Br$ gives the 9-α-naphthyl deriv., crystals with 1 mol. C_6H_6, m. 123° (decompn.); in attempting to remove the C_6H_6 H is evidently split off, since the product gives a deep yellow color with concd. H_2SO_4. Isoquinoline and PhLi give a product b_{14} 195–200°, m. 80°; *1-phenylisoquinoline picrate*, yellow, m. 165°. *p*-$MeOC_6H_4Li$ gives 1-*p*-anisylquinoline, whose *picrate*, yellow, m. 191°. Reduction of methylacridone with Na in AmOH or the action of MeLi on 9,10-dihydroacridine gives *10-methyl-9,10-dihydroacridine*, m. 93–5°. Catalytic reduction of acridine-9-carboxylic acid gives the 9,10-dihydro deriv., m. 205°; the 2 *Me esters* m. 128–30° and 160–2°, resp. The di-Li deriv. of methylacridone and Ph_2CCl_2 give *9-benzohydrylidene-10-methyl-9,10-dihydroacridone oxide*, m. 242°. C. J. West



Phthalazines. II. Joti Sarup Aggarwal, Ishwar das Khera and Jnanendra Nath Rây. *J. Chem. Soc.* **1930**, 2354–7; cf. *C. A.* **24**, 120.—The synthesis of phthalazines was extended to the prepn. of substances analogous to papaverine. Veratraldehyde (I) and $PhCH_2CONHNH_2$, heated with abs. EtOH contg. a little NaOH, give quant. *α-phenylacetyl-β-veratrylidenehydrazine* (II), m. 171–2°; heating with AmOH satd. with HCl or with $POCl_3$ in $CHCl_3$ gives *6,7-dimethoxy-1-benzylphthalazine*, yellow, m. 191–2°. Reduction of II with 3% Na-Hg gives *α-phenylacetyl-β-4,5-dimethoxybenzylhydrazine*, m. 129–30°. The following compds. were prepd. in a similar manner: *α-Phenylacetyl-β-piperonylidenehydrazine*, m. 210°; *6,7-methylenedioxy-1-benzylphthalazine* (III), m. 203–4°. *α-Phenylacetyl-β-p-methoxybenzylidenehydrazine*, m. 167°; *7-methoxy-1-benzylphthalazine* (IV), m. 168–9°; *picrate*, m. 208–9°; *α-phenylacetyl-β-p-methoxybenzylhydrazine* (V), m. 98–9°. *α-Phenylacetyl-β-m-methoxybenzylidenehydrazine*, m. 107–8°, is not converted into a phthalazine by the usual treatment; the *benzyl deriv.* m. 94–5°. The corresponding *o-MeO derivs.*, m. 141–2° and 79–80°. *α-Phenylacetyl-β-benzylidenehydrazine*, m. 148–9°; *benzyl deriv.*, m. 113–4°. 3,4-$(MeO)_2C_6H_3CH_2CO_2Et$ and $N_2H_4.H_2O$ give *3,4-dimethoxyphenylacetylhydrazine*, m. 115–6°; condensation with I and ring closure with $POCl_3$ give *6,7,3′,4′-tetramethoxy-1-benzylphthalazine*, m. 192–3°; *picrate*, m. 186–7°; this is without action on tubercle bacilli. V and $CuSO_4$ in EtOH yield the *Cu complex*, $C_{32}H_{14}O_{10}N_4SCu$, bluish green silky needles; acylhydrazines do not ppt. Cu quant. from solns. contg. less than 0.5% Cu. Hydrolysis of IV by heating with *o*-$C_6H_4(CO_2H)_2$ in EtOH at 100° for 6–8 hrs. and treatment with $PhNHNH_2$ gives *4-methoxy-2-phenylacetylbenzaldehyde diphenylhydrazone*, m. 122–3°. Similarly, III gives a *diphenylhydrazone*, m. 104–5°. C. J. West

The alkaloid of Shimmia repens, Nakai. Yasuhiko Asahina, Tatsuo Ohta and Mototaro Inubuse. *Ber.* **63B**, 2045–51(1930).—Surprisingly enough, *Skimmia repens*, Nakai, does not contain skimmianine, the alkaloid of *S. Japonica*, Thunb., but a base $C_{12}H_9O_2N$ (I) which proved to be identical with dictamnine obtained by Thoms from European *Dictamnus* roots. T. assigned to his compd. the compn. $C_{12}H_{11}O_2N$, but the present authors were unable to confirm this on a sample prepd. from Korean *Dictamnus*. Like T., they found one MeO group in I. I is unchanged by boiling MeI in an open dish but in a sealed tube rearranges into an isomer, *isodictamnine* (II), which splits off no Me by the Zeisel method. With EtI I gives *homoisodictamnine* (III), which likewise contains no alkoxyl group. With $KMnO_4$ I gives an aldehyde, *dictamnal*, $C_{11}H_9O_3N$ (IV), and an acid, *dictamninic acid*, $C_{11}H_9O_4N$ (V), which with concd. HCl or HBr splits off Me and CO_2 and forms 2,4-dihydroxyquinoline. Since V is not identical with *2-methoxy-4-hydroxyquinoline-3-carboxylic acid* (VI), it must be the 4,2-isomer. As I reacts with neither acylating nor C:O reagents, it very probably contains an ether O atom. I is therefore assigned the structure VII. Heated with BzCl and Bz_2O, it gives *N-benzoylnordictamnine* (VIII), sapond. by alc. KOH to *nordictamnine* (IX), also obtained directly from I with HBr. As N-free constituent was obtained a cryst. compd. m. 120° which, in spite of the similarity in m. ps., is apparently not identical (mixed, m. p.) with the fraxinellone of Thoms and Dambergis (*C. A.* 24, 2236). I (135 g. from 95 g. air-dry powd. leaves moistened with 10% Na_2CO_3 and extd. with petr. ether at 50°, the ext. then being shaken out with 5% HCl and the

acid soln. made alk. with Na_2CO_3 and extd. with $CHCl_3$), m. 132–3°, mol. wt. (Rast) 191.3; picrate, yellow, m. 165°; HCl salt, m. about 170° (decompn.). II, m. 188°, turns yellow and then brownish in the light, shows faint blue-violet fluorescence in alc. III, needles with 3 H_2O, m. about 80°, loses 2.5 mols. H_2O *in vacuo* and m. 143°; anhyd., it m. 150°. VIII (0.6 g. from 1 g. I, BzCl and Bz_2O at 130–5°), m. 165°. IX, m. 249°, gives II with alk. Me_2SO_4. IV (0.5 g. from 5 g. I), m. 259–60°, slowly sol. in alkalies; *phenylhydrazone*, yellow, m. 228°. V (yield, 3.0–3.5 g.), m. 260° (decompn.). VI (1 g. from 5 g. *o*-$O_2NC_6H_4COCH(CO_2Me)_2$ in alc. with Zn and HCl gas), m. 225°, gives a deep violet-red color with alc. $FeCl_3$. According to Thoms, Wolff, using a soln. of 0.05 g. I.HCl in 10 cc., "faintly turbid because of a slight sepn. of the free base," found the toxic dose for white mice to be about 0.33 mg./kg. body wt. and for *Rana esculenta* about 0.125 mg. The present authors find that 3 mg. pure I.HCl dissolves only partially in 0.8 cc. of 0.1 *N* HCl, so that W.'s soln. must have contained considerable free HCl. The lethal dose of I.HCl (H_2O suspension) for white mice was found to be at least 0.7 mg./g. and for *R. esculenta* 0.35 mg., and the same effects were obtained with about 0.4 and 0.15 mg. HCl, resp. I is therefore apparently not so toxic as has hitherto been assumed.

C. A. R.

Skimmianine. Yasuhiko Asahina and Mototaro Inubuse. *Ber.* 63B, 2052–6 (1930).—In connection with the study reported in the preceding abstr., Honda's work on the chemistry of skimmianine (I) has been repeated. His results have, in general, been confirmed and the compd. obtained did not depress the m. p. of a sample of H.'s prepn. Its compn., however, is $C_{14}H_{13}O_4N$, not $C_{22}H_{29}O_9N_4$. It contains 3 MeO groups and with MeI in a sealed tube yields an isomeric *isoskimmianine* (II) with only 2 MeO groups. The similarity in behavior of I and dictamnine indicates that the former is a di-MeO deriv. of the latter, a view supported by the almost identical absorption spectra of the 2 compds. I forms no Ac deriv., oxime or semicarbazone. $KMnO_4$ oxidizes it to an aldehyde, *skimmianal*, $C_{13}H_{13}O_6N$ (III), and *skimmianinic acid* (IV), and the IV with hot concd. HCl loses Me and CO_2 to form a *compd.* $C_{11}H_{11}O_4N$ (V) which yields a red *NO deriv.* (VI). On the other hand, II with hot concd. HBr gives a di-HO *compd* $C_{12}H_9O_4N$ (VII) which yields a diacetate and with alc. $FeCl_3$ forms a green color changed to wine-red by Na_2CO_3. V proved to be identical with the synthetic *7,8-dimethoxy 2,4-dihydroxyquinoline* (see following abstr.); I must, therefore, have the structure VIII and IV the structure IX. In addn. to the N-free skimmetin (umbelliferone), there was obtained a compd. m. 120° identical with that isolated from *Skimmia repens*. I (52 g. from 75 kg. air-dry leaves), cryst. powder or finely granular pyramids from alc. on rapid, light yellowish quadrangular columns on slow crystn., m. 176°, mol. wt. (Rast) 243–59; picrate, yellow, m. 195–7° (decompn.). II, m. 185°. VII, m. 218°; *diacetate*, m. 183°, gives no color with alc. $FeCl_3$. III, m. 238°, insol. in cold alkali and in Na_2CO_3 but sol. in hot alkali; *phenylhydrazone*, yellow, m. 210°. IV, m. 248°. V, m. 250°, easily sol. in alkali carbonates. VI, yellow-red, m. 247° (decompn.). The soln. which Honda used for his toxicity expts. contained many unknown substances besides I and it is not certain that the characteristic toxic action observed by him is to be ascribed to I exclusively.

(VIII)

(IX)

C. A. R.

Dimethoxy-2,4-dihydroxyquinoline. Yasuhiko Asahina and Sokichi Nakanishi. *Ber.* 63B, 2057–9(1930); cf. preceding abstr.—6- (I) and 2-nitro-3,4-dimethoxybenzoic acid (II) were prepd. from vanillin by the Pschorr and Sumuleanu method and converted with PCl_5 into the *chlorides* (III and IV) which were condensed with $CH_2(CO_2Et)_2$ by the Bischoff method to the *di-Et nitrodimethoxybenzoylmalonates* (V and VI) and these with Sn and hot HCl yielded *6,7-* (VII) and *7,8-dimethoxy-2,4-dihydroxyquinoline* (VIII). VIII proved to be identical with the product obtained from skimmianine. II, yellow, m. about 130°. V, brownish oil giving a deep red color with alc. $FeCl_3$. VII, does not m. 320°; *NO deriv.*, dark red, m. about 266° (decompn.). IV, m. 78°. VI, m. 108–10°, gives a red color with alc. $FeCl_3$. VIII, m. 250°; *NO deriv.*, violet-red, decomps. 248°.

C. A. R.

Sinomenine and disinomenine. XIX. Reduction of sinomenine and dihydrosinomenine with sodium amalgam. KAKUJI GOTO AND SHINGO MITSUI. *Bull. Chem. Soc. Japan* **5**, 282–90(1930); cf. *C. A.* **24**, 4044.—Dihydrosinomenine (I) is easily prepd. by catalytic reduction of sinomenine with Pd charcoal and H; it m. 198°, $[\alpha]_D^{25}$ 193.58° ($CHCl_3$), $[\alpha]_D^{24}$ 33.06° (dil. HCl); oxime, m. 211° (decompn.); semicarbazone, m. 209° (decompn.); methiodide, m. 268° (decompn.), soly. in H_2O at room temp. 0.34%. Reduction of I with Na-Hg (corresponding to 4 H) gives mixed crystals of *demethoxydihydrosinomeninol* (II) and demethoxydihydrosinomenine. Reduction of this mixt. with 5% Na-Hg (corresponding to 8 H) gives about 12.5% of pure II, m. 142° (decompn.), $[\alpha]_D^{30}$ 46.8° (MeOH); *methiodide*, m. 280°. The mother liquor of the above mixed crystals gives about 5% of *dihydrosinomeninol*, m. 162°, $[\alpha]_D^{30}$ 1.93° (MeOH); *methiodide*, decomps. 249°, $[\alpha]_D^{28}$ —6.73° (H_2O). This also results in 50% yield by the reduction of I in 6% AcOH with 5% Na-Hg (corresponding to 6 H). Reduction of sinomenine in AcOH with 5% Na-Hg (corresponding to 10 H) gives 30% of *sinomeninol*, m. 127°, $[\alpha]_D^{28}$ —23.7° ($CHCl_3$); *methiodide*, m. 272° (decompn.); catalytic reduction gives the dihydro deriv., m. 162°. C. J. WEST

A synthesis of *dl*-tetrahydropapaverine worthy of note for phytochemistry. ERNST SPÄTH AND FRANZ BERGER. *Ber.* **63B**, 2098–102(1930).—Robinson has suggested that the papaverine alkaloids may be formed by the condensation of an α-3,4-dihydroxyphenyl-β-aminoethane (formed from an NH_2 acid or otherwise) with $3,4\text{-}(HO)_2C_6H_3\text{-}CH_2CHO$ to norlaudanosine which then undergoes further simple transformations into the alkaloids. An attempt has been made to confirm this view by using, instead of phenols, their Me ethers. Homoveratraldehyde, prepd. by ozonization of eugenol Me ether, was allowed to react with homoveratrylamine; the next step (ring closure with HCl) offered difficulties because (1) the Schiff base was not sufficiently stable toward HCl, and (2) the aldehyde is rapidly resinified by HCl. Nevertheless, S. and B. were able to obtain 8% *dl*-tetrahydropapaverine. C. A. R.

Dealkylation of tertiary amines by organic acids. II. Nicotine. JULIUS v. BRAUN AND KARL WEISSBACH. *Ber.* **63B**, 2018–26(1930); cf. *C. A.* **24**, 2993.—From the results reported in the first paper, it was concluded that *N*-methylpyrrolidine heated with org. acids would not, as with BrCN, undergo ring cleavage almost exclusively but would chiefly, if not exclusively, exchange the *N*-Me group for the acid radical. The same behavior was to be expected of nicotine (I). Neither with BrCN nor with BzCl does it undergo any transformation leading to its conversion into nornicotine (II). M. and M. Polonovski had apparently effected such a conversion some years ago (*C. A.* **22**, 429) by the action of Ac_2O on the *N*-oxide but as their product, as indicated by its properties (rapid darkening and resinification in the air, difficult crystallizability of the salts), must have been at best very impure, v. B. and W. therefore undertook to bring about the conversion by their method and, after a no. of orienting expts., effected their object with relative ease. When I is gently boiled with acids like BzOH or $PhCH_2CH_2CO_2H$, 2 reactions take place: (1) opening of the ring and addn. of an acid residue to form the compd. $C_5H_4NCH(OH)CH_2CH_2CH_2NMeR$ (R = acyl radical), which by loss of H_2O gives the *N*-acylmetanicotine, $C_5H_4NCH{:}CHCH_2CH_2NMeR$ (III), and (2) normal formation of acylnornicotine (IV). III and IV, the relative amounts of which depend on the exptl. conditions, cannot be sepd. by distn. and the same is true of the secondary amines (V and VI) resulting from their sapon. V, however, adds HCl or HBr at the double bond at 150°; the resulting *Cl compd.* (VII) is quite stable, but the *Br compd.* (VIII), to which is assigned the structure $C_5H_4NCH_2CHBrCH_2\text{-}CH_2NHMe$, changes by intra- and extramol. loss of HBr into an Et_2O-insol. mixt. of HBr salts. The II is unchanged by the HBr treatment and can be isolated (through the *N*-NO deriv., if necessary) in quite pure form. The II so obtained is quite different from the product of the Polonovskis; it is characterized by its stability and forms well crystd. salts of definite m. p. Acid and alkyl groups can readily be introduced on the sec. N atom; the Et and allyl homologs of II obtained in this way are described in the present paper. These, as well as the Ac deriv. of II and II itself, differ from I in their pharmacol. action. I and 1 mol. BzOH yield 10% of a mixt., $b_{0.5}$ 210–20°, of III and IV (R = Bz). VII is so stable that it can be distd. in part without decompn. at 126–30° under 0.2 mm., while VIII decomps. so rapidly at room temp. that even the dil. Et_2O soln. becomes turbid and deposits oil droplets in 1 hr. When boiled with $PhCH_2CH_2CO_2H$, it yields the $PhCH_2CH_2CO$ derivs. of II, V and $C_5H_4NCH(OH)\text{-}CH_2CH_2CH_2NHMe$ (IX), $PhCH_2CH_2CO_2Et$, $PhCH_2CH_2CONHMe$ and, apparently, some free V and II. The longer the heating is continued, the smaller is the yield of

III and IV, and increase in the temp. favors reaction (1) at the expense of (2). II is obtained in 20% yield from $PhCH_2CH_2CO_2H$ gently boiled with 4–5 mols. I for 2.5 hrs. at a temp. not above 250–5°; it b. 266–7°, b_{12} 139–40°, d_4^{19} 1.044, [α] around —5.5° (probably some racemization occurs during the prepn.); *picrate*, m. 188–90°, depresses the m. p. of the picrate of V (163°) to 130–40°; *picrolonate*, m. 239–40°; HCl salt, oily; *chloroplatinate*, dark red, darkens 270°, decomps. 295°; *chloroaurate*, yellow, m. 217°; *NO deriv.*, yellow oil, $b_{0.5}$ 190–2°, whose *chloroplatinate* m. 190° and *methiodide*, hygroscopic, m. 144°. *Ac deriv.* of II, obtained with Ac_2O on the H_2O bath, faintly yellow, b_{12} 212–4°, $[\alpha]_D^{20}$ —3.24° (C_6H_6); *picrate*, light yellow, m. 151°; *chloroplatinate*, darkens 200°, decomps. 245°; *methiodide*, m. 201°. *Nornicotylurea*, from II in HCl with 1 mol. KCNO, m. 164–6°; *chloroplatinate*, red, darkens 250°, decomps. 270°. *Phenylthiourea*, m. 171°. The *HO base* IX, obtained in the prepn. of II, faintly yellow, $b_{0.5}$ 160–2°; *picrate*, m. 127–8°. The unchanged I recovered in the prepn. of II is to a large extent racemized ([α] —50° to —100°). *N-Ethylnornicotine*, from II and 1 mol. EtI in alc. (25% yield), b_{12} 127–8°; *HCl salt*, extremely hygroscopic; *chloroaurate*, yellow, decomps. 203°; *picrate*, m. 174–6°. *N-Allylnornicotine*, b_{12} 136–7°; *picrate*, m. 180–2°; *chloroaurate*, decomps. 145–8°; *chloroplatinate*, light orange, darkens 230°, decomps. 255°. C. A. R.

Resin of Garcinia mangostana L. Otto Dragendorff. *Ann.* **482**, 280–301 (1930).—The dried secretion of *Garcinia mangostana* L. (40 g.) on extn. with C_6H_6 gives 18 g. crude α-mangostin (I), 1.2 g. β-mangostin (II), 1.6 g. of a sterol (III) and 0.4–0.5 g. of an ethereal oil (IV). III, $C_{27}H_{46}O$, b_{11} 270°, m. 105–6°; Ac deriv., m. 113°. IV, $C_{15}H_{24}$, b_{11-12} 105°. I, yellow, m. 180–1°, sol. in 2 *N* NaOH, the yellow-brown soln turning darker in the air; concd. H_2SO_4 gives an orange-red soln.; $FeCl_3$ gives a grass-green color. Analysis and mol.-wt. detns. indicate the formula $C_{16}H_{16}O_4$ or $C_{16}H_{18}O_4$ for I; it contains 2 active H atoms. II, lighter yellow than I, m. 175.5°. Reduction of I gives a *tetrahydro deriv.*, b. 260°(high vacuum); Me_2SO_4 in 2 *N* NaOH gives an *α-Me deriv.*, m. 106°; an Ac deriv. could not be prepd. I and II give the same methylmangostin (V), m. 123°. I, boiled a short time with Ac_2O, gives a *mono-Ac deriv.*, yellow, m. 112°; boiling with Ac_2O and AcONa for 4 hrs. gives a *di-Ac deriv.*, yellow, m. 117°. V, AcONa and Ac_2O, boiled 3 hrs., give an *Ac deriv.*, m. 193–4° I and boroacetic anhydride in Ac_2O give *α-monoacetylmangostin boroacetate*, golden yellow, m. 206–7°. The *β-isomer*, golden yellow, m. 188°. V yields a *boroacetate*, yellow, m. 219°. I is unchanged after heating with 3% MeOH-KOH at 180° for 2 hrs. or by boiling with 30% MeOH-KOH for 3 hrs. A KOH melt gave only $BuCO_2H$ and AmOH. Oxidation expts. have thus far given no definite information as to the constitution of I or II. C. J. West

Syntheses of 4-carbolines. Ernst Späth and Edgar Lederer. *Ber.* **63B**, 2102–11(1930).—As harmine is at present of interest as a therapeutic agent, it seemed desirable to apply to the synthesis of other carbolines the method which had been devised for harmine (*C. A.* **24**, 2462). Tryptamine (I) or a substituted I is acylated on the primary N by heating with an org. acid or anhydride, and the *N*-acyl deriv. is converted with P_2O_5 in boiling xylene into the 5,6-dihydro-4-carboline which is subsequently dehydrogenated with Pd sponge to the 4-carboline. P_2O_5 proved far superior to HCl in aq. or abs. MeOH or to $POCl_3$ for the ring closure. Only in the prepn. of 4-carboline itself did the use of P_2O_5 prove unsuccessful; even in boiling tetralin *N*-formyltryptamine gave only 2% dihydro-4-carboline. To overcome this difficulty in prepg. 4-carbolines with no 3-substituent, an attempt was made to use in Kermack, Perkin and Robinson's method (condensation of tryptophan with HCHO and oxidation of the intermediate product with CrO_3) the more readily available I instead of tryptophan, but there was obtained neither 4-carboline with HCHO nor harman with AcH. The synthesis was effected, however, by condensing the tryptamine with HCHO to tetrahydro-4-carboline and dehydrogenating the product. Under the same conditions as used by K., P. and R. with tryptophan, moderate yields of the tetrahydro compd. can be obtained, to be sure, but by a systematic study S. and L. have been able to increase the yield to 65%. An excess of HCHO and too strong acidity must be avoided. Short heating suffices for the condensation to the Schiff base but not for the cyclization to the tetrahydrocarboline. The dehydrogenation was effected with Pd sponge, as with the dihydro compds., but temps. less than 200° had to be used to avoid the formation of compds. of high mol. wt. and high sublimation point. A series of 4-carbolines was prepd. to test the applicability of the method. *3-Ethyl-5,6-dihydro-4-carboline* (II) (0.45 g. from 0.65 g. I and $EtCO_2H$), m. 172–3°; *picrate*, m. 226° (foaming). *3-Ethyl-4-carboline* (III), from the dihydro compd. and Pd sponge at 170°, m. 194–5°. *3-Pr homolog*

of II (1.01 g. from 0.985 g. I), m. 182–3° (*picrate*, m. 231° (decompn.)); of III, m. 211–2° (the HCl salt shows strong blue fluorescence in dil. soln.). *3-iso-Pr homolog* of II (0.32 g. from 0.6 g. I), m. 178–9° (*picrate*, m. 232–5° (blackening)); of III, m. 162–3°. *3-Ph analog* of II (0.168 g. from 0.3 g. I through the *N*-benzoyltryptamine, m. 137–8°), m. 221–2° (*picrate*, m. 240° (foaming)); of III, m. 246–7°. *1-Methyltryptamine* (IV), from $PhNMeNH_2$, $H_2NCH_2CH_2CH_2CH(OEt)_2$ and $ZnCl_2$ at 180°, $b_{0.2}$ 140–70° (bath temp.); *picrate*, yellow, m. 180–1°. IV absorbs CO_2 from the air, forming a cryst. carbonate. *1-Methylharmalan* (0.116 g. from 0.3 g. IV treated with Ac_2O and then with P_2O_5), m. 91–2° (*picrate*, m. 245° (foaming)), dehydrogenated by Pd sponge to *N-methylharman*, m. 102–3°. *1-Methyl-3-ethyl homolog* of II (0.22 g. from 0.4 g. IV), b_1 160–200° (*picrate*, m. 195° (foaming)); of III, m. 124–5°. *5-Methoxytryptamine*, from *p*-$MeOC_6H_4NHNH_2$ and $H_2NCH_2CH_2CH_2CH(OEt)_2$, m. 120–1°; *picrate*, ruby-red, m. 214–5° (foaming). *10-Methoxyharmalan*, m. 208–9°; *10-methoxyharman*, m. 273–4°. *7-Methoxytryptamine*, from *o*-$MeOC_6H_4NHNH_2$, m. 135–6°. *12-Methoxyharmalan*, m. 182–3° (*picrate*, blackens 290°); *harman*, m. 239–40°. *3,4,5,6-Tetrahydro-4-carboline* (V) (65% yield from 0.1 g. I in 6 cc. dil. H_2SO_4 (2 vols. H_2SO_4: 250 vols. H_2O) and 3 drops of 40% HCHO heated 1 min. on the H_2O bath, cooled, made alk., extd. with Et_2O, evapd. and refluxed 45 min. in the above dil. H_2SO_4), m. 207–8°, gives with Pd sponge at 165° 4-carboline, m. 197–8° (VI). *1-Me deriv.* of V, $b_{0.3}$ 140–70°; of VI, m. 108–9°, shows strong blue fluorescence in dil. HCl soln. (*picrate*, m. 258° (foaming)). *10-MeO deriv.* of V, m. 223–4°. *12-MeO deriv.*, m. 217–8°; *picrate*, m. 217–8°. C. A. R.

Porphyrin syntheses. XXXIV. Synthesis of isouroporphyrin I. H. Fischer and Reinhold Siebert. *Ann.* **483**, 1–17(1930); cf *C. A.* **25**, 110—F. and Heisel (*C. A.* **22**, 1132) prepd. isouroporphyrin II by treating 4,4′-dimethyl-3,3′-di-β-methylmalonic acid-dipyrrylmethane-5,5′-dicarboxylic acid with HCO_2H at 40°; the present work describes the prepn. of an isomeric compd. *2,4-Dimethyl-5-carbethoxypyrryl-3-β-methylmalonic acid*, m. 192°, results by the hydrolysis of 7 g. of the di-Et ester with 2.5 g. NaOH in 80 cc. EtOH; *di-Me ester*, m. 127°. Further hydrolysis gives *2,4-dimethyl-5-carboxypyrryl-3-β-methylmalonic acid* (I), decomps. 85°; *tri-Me ester*, m. 125°; partial esterification was not effected. A cold soln. of I in MeOH, treated with HCl for 30 min., gives the *methene-HCl*, $C_{26}H_{33}O_8N_2Cl$, golden yellow, decomps. 211°. I in AcOH with Br-AcOH gives *3,4′-di-β-methylmalonic acid-4,3′,5′-trimethyl-5-bromopyrromethene-HBr*, yellow, decomps. 181°; *tetra-Me ester*, yellow, m. 113°; *HBr salt*, decomps. 202°; *Cu complex*, $C_{48}H_{56}O_{16}N_4Br_2Cu$, needles with green metallic luster, decomps. 152°; *Zn complex*, decomps. 149°; *Ni salt*, needles with metallic luster, decomps. 147°; *Cd salt*, decomps 115°; *Mn salt*, decomps. 153°; *Co salt*, blue metallic luster, decomps. 151°. Heating with satd. HCO_2H-HBr 6 days at 45–50° gives the *tetra-Me ester* of *isouroporphyrin* I, m. 284° and giving a sharp depression with the ester of natural uroporphyrin and isouroporphyrin II; *Cu complex*, $C_{48}H_{52}O_{16}N_4Cu$, m. 289°; heating with 1% HCl 4 hrs. at 180° gives coproporphyrin I. The new compd. is thus *1,3,5,7-tetramethyl-2,4,6,8-tetramethylmalonic acid-porphin*. C. J. West

Crystalline irradiated products from ergosterol and dehydroergosterol. A. Windaus, J. Gaede, J. Köser and G. Stein. *Ann.* **483**, 17–30(1930).—Ergosterol in EtOH, subjected to the action of Hg light at about 75° for 50 hrs., gives a mixt. of *suprasterol I* (I) and *II* (II), sepd. as the allophanates, of which that of I seps. first from C_6H_6. I m. 104°; the Liebermann-Burchard color reaction is olive-green; chloral hydrate at 100° gives a very deep red-violet color; the reactions with Cl_3CCO_2H, $AsCl_3$ and $SbCl_3$ are not characteristic. I appears to be less sensitive to air than ergosterol and vitamin D; yet it is slowly changed in the air, turning yellow and having a lowered m. p.; it is not changed by ultra-violet light; I may be distd. at 0.002 mm. and 190° without change; it is not changed by Na and EtOH. *Benzoate*, m. 96°, $[\alpha]_D^{18}$ −50.0° ($CHCl_3$); *allophanate*, amorphous, m. about 219°, $[\alpha]_D$ −40° ($CHCl_3$). II, m 110°, $[\alpha]_D^{19}$ 62.9° ($CHCl_3$), $b_{0.005}$ 190°; the color reactions are like I. II is not reduced by Na and EtOH. *Oxalate*, m. 165°, $[\alpha]_D^{17}$ 75.3° ($CHCl_3$); *allophanate*, m. 224°, $[\alpha]_D^{18}$ 80° ($CHCl_3$). Catalytic reduction with Pt oxide appears to give a dihydro deriv; further reduction with Pt and AcOH at 70° gives a satd. alc. and a hydrocarbon but ergostanol and epiergostanol were not found. I and II do not show a general absorption beyond 250 mμ. The 2 new compds. are not pptd. by digitonin. Photodehydroergosterol gives a *benzoate*, m. 160°, $[\alpha]_D^{18}$ 134.1° ($CHCl_3$); *phenylurethan*, m. 130°, $[\alpha]_D^{18}$ 98.7° ($CHCl_3$). Catalytic reduction of the Ac deriv. gives a *tetrahydro Ac deriv.*, $C_{29}H_{46}O_2$, m. 106°, $[\alpha]_D^{18}$ 3.8°; the *tetrahydro deriv.* m. 123°, $[\alpha]_D^{18}$ 26° ($CHCl_3$); *benzoate*,

m. 82–3°, $[\alpha]_D^{18}$ 50.2° ($CHCl_3$). The *compd.* $C_{28}H_{28}O_4$, m. 257°, is also obtained in the action of light on dehydroergosterol. C. J. West

---

A sterol-like compound from the sepals of the sunflower (Zechmeister, Tuzson) 11D. Sphingomyelin (Merz) 11A. Investigation of the structure of organic liquids in the interior and on the surface (Trillat) 2. Salts and esters of humic acids (Fuchs, Horn) 21.

Heterocyclic bases and nitriles. I. G. Farbenind. A.-G. Brit. 332,623, Feb. 22, 1929. Unsatd. hydrocarbons such as C_2H_2, butadiene, or aldehydes such as acetaldehyde, or mixts. contg. them, together with NH_3 or aliphatic or aromatic amines such as $PhNH_2$, $PhNMe_2$ or the like, are passed in the presence of steam and preferably at temps. of 300–500° (and suitably under pressures up to 20 atm.) over catalysts free from S and S compds. and contg. compds. of metals of the second to seventh groups of the periodic system, at a rate of at least 10 l. of unsatd. hydrocarbon or aldehyde or both per hr. per l. of catalyst. As catalysts there may be used: bauxite, metal oxides such as those of Cd, Al, Zr, Th, Sn, V, Bi, Mo or W or combinations of these with metals such as Cd, Pb, Sn, Sb or Bi. Various examples are given of the production of mixts. contg. quinoline or pyridine bases, nitriles, picolines, etc., suitable for use as solvents, for denaturing alc., destroying "pests," etc. Cf. *C. A.* 24, 2468.

Ethers. N.-V. de Bataafsche Petroleum Maatschappij. Brit. 332,756, Aug. 1, 1929. Aliphatic alcs. contg. at least 2 C atoms in the mol. are heated under pressure in the presence of a dehydration catalyst such as Al oxide or sulfate or Th oxide, at a temp. not exceeding 400° (preferably below 300°). Examples are given of the production of diethyl ether, dipropyl ether (with some propylene), diisopropyl ether, dibutyl ether and diisobutyl ether from the corresponding alcs. The ethers may be used in solvents for *nitrocellulose lacquers*, as in a mixt. comprising butyl ether 10, isopropyl ether 10, toluene 50, EtOH 10, EtOAc 10 and xylene 10%.

Nitro- and amino-aryl ethers. I. G. Farbenind. A.-G. (Arthur Zitscher, inventor). Ger. 506,339, Dec. 25, 1926. *o*-Nitrophenylaryl ethers are prepd. by the action of alkali phenolates or naphtholates on *o*-dinitro compds. of the C_6H_4 series in the presence or absence of solvents or diluents. Reduction by the usual methods yields the corresponding *o*-aminodiaryl ethers, which are *dye intermediates*. Thus, a mixt. of 3,4-dinitro-1-chlorobenzene and PhOK, warmed for 1 hr. on the water bath, yields *5-chloro-2-nitrodiphenyl ether*, m. 85°, reducible to *5-chloro-2-aminodiphenyl ether*, m. 40–41°. Other examples are given also describing the prepn. of (*interalia*) *5-methyl-2-nitrodiphenyl ether*, m 63.5–64.5°, *5,2',5'-trichloro-2-nitrodiphenyl ether*, m. 97–98°, and *5,2',5'-trichloro-2-aminodiphenyl ether*, m. 74–75°.

Vinyl ethers. I. G. Farbenind. A.-G. Brit. 332,605, March 22, 1929. Vinyl monohalides or their homologs contg. at least 1 H atom connected to the C atom of the double bond which is free from halogen are treated with aliphatic, cycloaliphatic or aliphatic-aromatic alcoholates or phenolates in the presence of org. diluents, or mixts. of alcs. with oxides or hydroxides of alkali or alk. earth metals may be used instead of alcoholates, and alcs. or phenols may serve as diluents. Examples are given of the prepn. of vinyl methyl ether, vinyl butyl ether, vinyl phenyl ether, vinyl *o*-cresyl ether, vinyl *m*-cresyl ether, vinyl α-naphthyl ether, vinyl β-naphthyl ether, ethyl isopropenyl ether and ethyl 1,2-dimethylvinyl ether. 2-Chloro-β-butylene (used in prepg. ethyl 1,2-dimethylvinyl ether) is made by splitting off HCl from 2,3-dichlorobutane by use of KOH. Cf. *C. A.* 24, 5306.

* **Aminonaphthol ethers.** Arthur Zitscher (to General Aniline Works). U. S. 1,784,408, Dec. 9. Aminonaphthol ethers are obtained by treating hydroxynaphthalenecarboxamides with alkylating agents and subjecting the ethers of naphtholcarboxamides, thus obtained, to the action of alkali metal salts of HOCl or HOBr according to Hofmann's decompn. reaction. 2,3-Aminonaphthol methyl ether crystallizes from ligroin as colorless brilliant needles, m. about 107°. 2,1-Aminonaphthol ethyl ether crystallizes from alc. as brilliant colorless lamellae, m. 48–9°. 2,6-Aminonaphthol benzyl ether crystallizes from toluene as colorless lamellae, m. about 176°. 2,6-Aminonaphthol methyl ether m. about 156–7°.

Aromatic hydroxy aldehydes. Gustav Reddelien, Hans Langer and Hugo Pfannenstiel (to Winthrop Chemical Co.). U. S. 1,783,584, Dec. 2. See Ger. 494,432 (*C. A.* 24, 2755).

Esters of monocarboxylic acids. I. G. Farbenind. A.-G. (Johannes Brode and Georg Käb, inventors). Ger. 506,437, Mar. 1, 1929. Addn. to 445,565. Ger. 445,565

describes the manuf. of monocarboxylic acids by treating dicarboxylic acids or their anhydrides in the vapor phase and at a raised temp. with steam in the presence of a catalyst, *e. g.*, a metal oxide, silicate or stable carbonate. This process is now modified by using an alc. vapor instead of steam, whereby esters are obtained directly. Thus, a mixt. of MeOH and phthalic anhydride vapors dild. with N, passed over ZnO at 380°, yields methyl benzoate. Other examples are given also.

1-Sulfoaryl-5-pyrazolone-3-carboxylic acid esters. I. G. FARBENIND. A.-G. (Heinz Eichwede and Erich Fischer, inventors). Ger. 504,771, Nov. 28, 1924. See U. S. 1,766,813 (*C. A.* **24**, 4306).

Alkylated phenols. HANS JORDAN (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,782,966, Nov. 25. In reactions such as production of *p*-isopropylphenol and phenol (from *p*-dihydroxydiphenyldimethylmethane), production of 2-methyl-4-isopropylphenol and *o*-cresol (from 4-dihydroxy-3-dimethyldiphenyldimethylmethane) and production of *p*-isobutylphenol and phenol (from *p*-dihydroxydiphenylmethylethylmethane), hydrogenation is effected at a temp. of about 160° and in the presence of a slow-acting hydrogenation catalyst such as a Ni catalyst contg. Bi.

Hydrogenation products of alkylated phenols. HANS JORDAN (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,782,621, Nov. 25. Isopropylcyclohexanol is produced by treating *p*-dihydroxydiphenyldimethylmethane with H under pressure at 170° in the presence of a Ni catalyst contg. Mn until 14 H atoms have been fixed, and subjecting the product to fractional distn. Examples also are given of the production of 1-methylcyclohexanol and 1-methyl-4-isopropylcyclohexanol from 4-dihydroxy-3-dimethyldiphenyldimethylmethane and of the production of 4-isobutylcyclohexanol and some cyclohexanol from *p*-dihydroxydiphenylmethylethylmethane, by similar hydrogenation. Cf. *C. A.* **24**, 4521.

Metal carbamates. I. G. FARBENIND. A.-G. Brit. 332,584, March 20, 1929. The process of producing metal carbamates previously described is modified by the reaction upon a soln. or suspension of a metal compd. (such as NaCl, $CaCl_2$ or $Ca(OH)_2$, BaO, $Zn(NO_3)_2$ or K compds.) in an inert liquid such as EtOH, MeOH or other alc., formamide or liquid NH_3 (which may contain NH_4NO_3 or a small proportion of water), of NH_4 carbamate, to produce the carbamate of the metal, a compd. of which is used. Cf. *C. A.* **24**, 5115.

Alkyl formates. RUDOLF WIETZEL (to I. G. Farbenind. A.-G.). U. S. 1,782,591, Nov. 25. In the manuf. of an alkyl formate such as methyl formate, a liquid aliphatic alc. such as MeOH is acted on with a gas comprising CO together with a substantial amount of an inert gas such as H or N. Purified producer gas may be used. Cf. *C. A.* **24**, 3516.

Alkyl chlorides. JOHN FREI (to E. I. du Pont de Nemours & Co.). U. S. 1,784,423, Dec. 9. In making an alkyl chloride such as EtCl a mixt. of an aq. HCl soln. and an alc. such as EtOH is heated to above 110° in the presence of $FeCl_3$ while permitting the escape of the water vapors formed.

Tetraalkylated thiuram disulfides. HAROLD S. ADAMS and LUDWIG MEUSER (to Naugatuck Chemical Co.). U. S. 1,782,111, Nov. 18. Tetramethylthiuram disulfide is made by treating dimethylamine with CS_2, oxidizing the alkyl dithiocarbamate thus formed to tetramethylthiuram disulfide with H_2O_2 and simultaneously causing the liberated dimethylamine to be converted into addnl. alkyl dithiocarbamate by the addn. of excess CS_2 and oxidized to tetramethylthiuram disulfide until substantially all the dimethylamine has been converted, and recovering tetramethylthiuram disulfide from the reaction mixt. Other tetraalkylated thiuram disulfides may be similarly produced. Various details of procedure are given. U. S. 1,782,112 relates to similar processes.

Splitting sulfo groups from anthraquinonesulfonic acid derivatives. ROBERT E. SCHMIDT (to General Aniline Works). U. S. 1,782,747, Nov. 25. A compd. such as *p*-dimethylaminoanthrarufin-2,6-disulfonic acid is treated in substantially neutral soln. with Na hyposulfite, and the resulting hydro compd. is treated with an alk. agent such as NaOH. Numerous examples of similar reactions are given, with details of procedure.

Substituted guanidines. RALPH V. HEUSER (to American Cyanamid Co.). U. S. 1,784,442, Dec. 9. In the formation of substituted guanidines such as methylphenylguanidine, cyanogen chloride (free from substantial amounts of Cl and HCl) is brought into contact with a secondary arylalkylamine and reaction between the materials is effected in a single operation. Several examples are given.

Guanidine derivatives. J. D. RIEDEL-E. DE HAËN A.-G. (Karl Heinrich, Slotta Rudolf Tschesche and Erich Hesse, inventors). Ger. 504,996, Feb. 24, 1928. These

are prepd. by the action of guanidine or its salts on thiocyanates of the formula R-N:C:S (where R = an aliphatic or substituted aromatic residue) in soln. in the warm. In an example, guanidine thiocyanate and methyl mustard oil are dissolved in anhyd. alc. Na is added and the soln. heated in a water bath. The residue is taken up in water and the soln. treated for 3–4 hrs. with CO_2. The carbonate of methylguanylthiourea is pptd. in a 75% yield. The free base m. 159°. Other examples are given.

Guanidine derivatives. SCHERING-KAHLBAUM A.-G. (Herbert Schotte, inventor). Ger. 506,282, Oct. 29, 1926. Highly alkylated guanidines are prepd. by heating salts of alkylamines or alkylenediamines having 5 or more C atoms in the mol., with approx. an equimol. amt. of cyanamide or its derivs. Thus, isoamylamine sulfate, warmed for 6 hrs. with an alc. soln. of cyanamide, yields isoamylguanidine sulfate, m. 266°. Other examples are given also. Cf. *C. A.* **24**, 4307.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. (Georg Kränzlein, Martin Corell, Heinrich Vollmann and Emil Hausdörfer, inventors). Ger. 506,440, Sept. 10, 1927. Addn. to 495,335. The method of Ger. 495,335 (*C. A.* **24**, 3249) is extended to the prepn. of 2-haloanthraquinone-3-carboxylic acids from 3-aminoanthraquinone-2-sulfonic acid and its substitution products. Examples are given.

Anthraquinone derivative. I. G. FARBENIND. A.-G. (Georg Kränzlein and Heinrich Vollmann, inventors). Ger. 506,439, Dec. 10, 1926. *α-(2-Carboxyphenyl)anthraquinone*, m. 236°, is obtained as the sole product of oxidation when *Bz*-1,2-benzobenzanthrone is treated in the warm with CrO_3 in AcOH soln. An example is given.

Perylene derivatives. FELICE BENSA. Ger. 506,281, Aug. 18, 1925. 3,9-Dicyanoperylene, m. above 360°, is prepd. by heating 3,9-dichloro- or 3,9-dibromoperylene with CuCN. The reaction may be effected in the presence of a solvent, *e. g.*, pyridine or quinoline, and under these conditions a monochloromonocyanoperylene, m. 316°, is obtainable from the dichloro compd. Pressure may also be applied. Examples are given.

Naphthalene derivatives. I. G. FARBENIND. A.-G. (Richard Herz, Werner Zerweck and Fritz Schulte, inventors). Ger. 506,444, Dec. 10, 1926. Addn. to 505,322. The treatment of *o*-cyanonaphthalenesulfonic acids described in Ger. 505,322 (*C. A.* **24**, 5766) is now applied to 1-cyanonaphthalene-4-sulfonic acid and its nuclear substitution products. The reactions may be effected in an open vessel or under pressure. Examples are given.

Mono- and di-halogen-substituted naphthalene derivatives. EDGAR C. BRITTON and WM. R. REED (to Dow Chemical Co.). U. S. 1,784,267, Dec. 9. Naphthalene is subjected to not more than the theoretically required proportion of a halogen such as Br or Cl in a liquid vehicle such as benzene, toluene, a xylene or a chlorobenzene (suitably with a catalyst such as Fe in effecting the production of α-chloronaphthalene, etc.).

Acetic acid from methanol and carbon monoxide. HENRY DREYFUS. U. S. 1,784,583, Dec. 9. MeOH and CO are heated together under substantially atm. pressure to between 100° and 500° (generally 200–350°) in the presence of a catalyst comprising a metal the acetate of which decomposes with formation of HOAc at temps. such as are employed. As catalysts, there may be used oxides, acetates, methylates or other suitable compds. of Cu, Sn, Pb, Zn or finely divided metals such as Zn, Al or Cu.

Chloroacetic acid. HORST BRÜCKNER. Ger. 506,280, Feb. 26, 1927. AcOH is chlorinated at a raised temp. in the presence of a catalyst comprising a mixt. of red P, chlorides of P and I. An example is given.

Aromatic carboxylic acids. I. G. FARBENIND. A.-G. (Friedrich Hans, inventor). Ger. 506,438, Feb. 5, 1926. Addn. to 494,110. The method of Ger. 494,110 (*C. A.* **24**, 2759) is now extended to the oxidation of aromatic aldehydes in general to the corresponding acids. Examples are given.

Acetylene from methane. R. M. WINTER, P. H. HULL, J. FERGUSON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 332,731, July 12, 1929. CH_4, or gases contg. CH_4, are mixed with O or air and the mixt. is passed through a reaction zone (suitably a silica tube without packing) at a temp. above 1000°. The proportion of O is kept as high as possible while avoiding explosion, and H in the mixt. is desirable. A gauze or mass of metal turnings is used to prevent back-firing.

Acetaldehyde. I. G. FARBENIND. A.-G. Brit. 332,635, April 22, 1929. A mixt. of C_2H_2 and steam is passed over a catalytic mass free from water of hydration, comprising Al oxide activated by one or more dehydrogenating catalysts such as Cd or Zn oxides or sulfides or mixts. of these with chromate, tungstates or molybdates. Examples are also given involving the use of Ni or Co oxides with Al oxide and also in-

volving the use of Cu and Fe sulfides, etc. Temps. of 150–500° are suitable. Cf. *C. A.* **24**, 5768.

Ethylamine. I. G. FARBENIND. A.-G. (Rudolf Wietzel, inventor). Ger. 479,079, Apr. 4, 1925. C_2H_4 and NH_3 are caused to react at a raised temp. and pressure in the presence of a catalyst, *e. g.*, the product obtained by reducing NH_4 molybdate in H. An example is given.

Phenols. HANS JORDAN, WALTER SCHOELLER and REINHARD CLERC (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,784,599, Dec. 9. In producing a satd. phenol such as thymol, H under pressure and in the presence of a hydrogenation catalyst is caused to act at a temp. of 180–320° on a product obtained by condensation in the presence of an acidic condensing agent such as HCl of an alkyl phenol such as *m*-cresol and an aliphatic ketone such as acetone.

Cresol recovery from aqueous solutions. HERMANN SUIDA. U. S. 1,784,711, Dec. 9. An aq. soln. contg. cresol such as that obtained in HOAc concn. is treated with C_2HCl_3, the soln. of C_2HCl_3 and cresol is sepd. from the water and the C_2HCl_3 and cresol are sepd. from each other by distn.

Borneol and limonene. YOSHIO TANAKA and TSUTOMU KUWATA. U. S. 1,784,165, Dec. 9. Pinene or a material contg. pinene is treated with org. acids (such as oxalic acid at 50–100°) in the presence of silica gel as a catalyst, the limonene is distd. and the remaining borneol ester is saponified.

Thymol. WALTER SCHOELLER, HANS JORDAN and REINHARD CLERC (to Chemische Fabrik auf Actien vorm. E. Schering). U. S. 1,784,598, Dec. 9. The product obtained by condensing a crude cresol (substantially a mixt. of *m*- and *p*-cresol) and acetone in the presence of an acid-condensing agent such as HCl is heated (suitably at a temp. of about 300°) to effect decompn. and the decompn. product is treated with H in the presence of a hydrogenation catalyst until 2 H atoms have entered into combination, and the resulting mixt. of thymol and *p*-thymol is subjected to careful fractional distn. Cf. *C. A.* **24**, 4307.

Urea. HARRY C. HETHERINGTON and HERBERT J. KRASE (to Arthur B. Lamb, trustee). U. S. 1,782,723, Nov. 25. In a continuous process for producing urea by heating NH_3 and CO_2 under pressure, the NH_3 and CO_2 which are not converted to urea are sepd. from each other and are then separately returned to the urea-forming system.

Refining anthracene. CHARLES J. THATCHER. U. S. 1,782,488, Nov. 25. Impure anthracene is ground with a solvent such as CCl_4 in such proportion as selectively to dissolve impurities such as oils and phenanthrene and the resulting soln. is sepd. from the purified anthracene. Carbazole may be subsequently removed from the residue.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

A criticism of Einthoven's law in electrocardiography. ERNEST B. ZEISLER. *Proc. Soc. Exptl. Biol. Med.* **28**, 12–5(1930).—The discussion develops the theorem: A necessary and sufficient condition for Einthoven's law is that Einthoven's triangle be equilateral. It has been repeatedly claimed that this law held *exactly* in electrocardiography. This is obviously an erroneous statement; the line of a lead changes as the elec. axis moves; it may never be in the same plane as the line joining the 2 electrodes; an electrocardiographic lead does not record accurately the projection on a single line of the cardiac potential. The law holds approx. and is of practical use. This refutation is for the sake of scientific accuracy. C. V. BAILEY

The question of the individuality of erepsin. EMIL ABDERHALDEN AND ELLA VON EHRENWALL. *Fermentforschung* **12**, 223–30(1930).—Erepsin prepns., which are entirely free from trypsin, hydrolyze chloroacetyl-*d*-alanine and chloroacetyl-*dl*-leucine but not chloroacetyl-*l*-tyrosine. On the other hand, erepsin-free trypsin prepns. hydrolyze chloroacetyl-*l*-tyrosine and chloroacetyl-*dl*-leucine but not chloroacetyl-*d*-alanine. Thus far no other haloacylamino acids have been hydrolyzed by trypsin-free erepsin. From the biol. point of view it is difficult to see what significance would be attached to an enzyme specific for a substance like chloroacetylalanine which does not occur in nature. The affinity between enzyme and substrate must be especially great

in this instance. It remains to be seen whether an enzyme can be sepd. from erepsin, which would be active toward chloroacetyl-*d*-alanine but leave di- and polypeptides unaltered. Such a sepn. has already been accomplished in the trypsin complex. It has been shown that the specificity of certain enzymes alters with aging. Thus a trypsin prepn. which initially showed no ereptic action readily hydrolyzed leucylglycine after having been kept 1–3 months. Similarly an erepsin prepn. lost its power of hydrolyzing leucylglycine and became active toward tetrapeptides. Perhaps such changes are due to alterations in the inhibitory substances originally present, or else accessory substances undergo changes whereby new activities develop. A. W. Dox

The activator Z and its relation to the growth factor of yeast, bios and the vitamins B. Torb Philipson. *Z. physiol. Chem.* **193**, 15–45(1930).—The discovery of the specific fermentation activator Z (Euler and Swartz, *C. A.* **19**, 525) and the subsequent identification (Eastcott, *C. A.* **22**, 3897) of inositol as a component of bios suggest the desirability of comparing the properties of Z with those of bios and vitamin B_1, and of detg. the role of inositol. After successive treatments of the dialyzate with $Pb(OAc)_2$, $Ba(OH)_2$ and $HgSO_4$, a procedure which ppts. B_1 quantitatively, the Z activity remained entirely in the filtrates. This demonstrates the non-identity of Z with B_1. The methods by which bios is sepd. into bios I and II, *viz.* pptn. by $Ba(OH)_2$ and EtOH, and pptn. by $Pb(OAc)_2$, were applied to the dialyzate contg. Z. The latter, like bios II, remained entirely in the filtrate, but unlike bios II it showed no growth-promoting action. Bios and Z are therefore not identical. Furthermore, addn. of inositol to the filtrate did not confer any growth-promoting properties. The Z activator is rather easily sol. in concd. EtOH, about 3000 units dissolving in 1 l. of 95% EtOH. By pptg. the dialyzed Pb filtrate with $HgCl_2$ and adding NaOH to p_H 10 a partial sepn. is effected. The sum of the sep. activities of the 2 fractions thus obtained is approx. equal to the activity of the original soln. The activity of the combined fractions, however, is less than that of the original soln. Addn. of inositol to fraction II compensates the loss of activity incurred by the removal of fraction I. It appears, therefore, that activator Z is not an individual substance. Whether its components have an additive effect, or a mutual influence in the sense of enzyme and coenzyme, is not yet detd. A. W. D.

Acetyl bases from proteins. Niels Troensegaard, Fritz Wrede and H. G. Mygind. *Z. physiol. Chem.* **193**, 49–55(1930); cf. *C. A.* **20**, 3017.—Finely powd. dry protein was treated with HBr in AcOH, whereby the greater part was dissolved, then the mixt. was refluxed with successive portions of AcCl, evapd. to a sirup, and the latter heated in an oil bath with Ac_2O and NaOAc. The evapn. residue was extd. with Et_2O, the residue dissolved in AcOH and treated with Et_2O to ppt. the acetylprotein, and the latter given a further acetylation treatment. The combined Et_2O exts. contg. the "acetyl bases" were evapd. and fractionated *in vacuo*. The first fraction up to 100° at 15 mm. consisted mainly of AcOH, Ac_2O and $AcNH_2$. Fraction II from 80° to 130° at 0.3 mm. contained some Ac_2NH and Ac_3N, and a *base* $C_{10}H_{14}N_2O_2$ which was isolated as the *chloroaurate*, m. 193°. The HCl salt of this base gave no ppt. with EtOH or with alc. $H_4Fe(CN)_6$, an oily ppt. with picric acid, a copious ppt. with phosphotungstic acid, neg. reactions for NH_2, MeO and MeNH, neg. diazo and Millon reactions, and no acyl deriv. with *m*-$O_2NC^6H_4COCl$ or $PhSO_2Cl$. Fraction III, obtained from 130° to 200° at 0.3 mm., yielded a *base* $C_8H_{11}N_3O$, which was isolated as the *chloroaurate*, m. 184° (decompn.). It formed a *chloroplatinate* which blackened at 260° without melting; a *hydrochloride* which gave pos. diazo and Zimmerman reactions, and neg. biuret, Van Slyke, Millon, MeO and MeNH tests; and a *m-nitrobenzoyl deriv.*, m. 185°. Both bases were obtained from serum globulin, serum albumin, globin, fibrin and casein. Gliadin gave only the C_5 base, while silk fibroin gave neither one. The yield of bases averaged 0.5% of the protein. A. W. Dox

Sphingomyelin. Wilhelm Merz. *Z. physiol. Chem.* **193**, 59–87(1930).—Sphingomyelin was prepd. from human brain and purified until the P:N ratio was 1:2. Its properties agreed with those described by Levene, except that $[\alpha]_D$ was 5.31–5.83° instead of 7.5–8.2°. Catalytic hydrogenation increased the rotation to 12.85°, and acetylation of the hydrosphingomyelin gave an Ac deriv. with Ac content in agreement with that calcd. on the basis of 1OH. All evidence thus far substantiates the structural formula proposed by Levene. The only uncertainty is in regard to the fatty acid component. An elaborate fractionation was made by fractional extn. with MeAc in which sphingomyelin is difficultly sol., but all 6 fractions showed approx. the same compn. All contained the 3 acids, stearic, lignoceric and nervonic. Conclusion: Sphingomyelin is a mixt. of 3 substances differing only in their fatty acid component. These 3 sphingomyelins are of the same structure as the cerebrosides except that they contain a phosphoric acid choline ester in place of galactose. A. W. Dox

The influence of a mash of onions on the formation of Liesegang's rings. A. Th. Czaja. *Biol. Zentr.* 50, 577–81(1930).—The disturbance on the formation of Liesegang rings in gelatin can be observed with all parts of the onion (*Allium cepa*). It is due to the action of allyl sulfide and of allyl thiocyanate. Mitogenetic irradiation has nothing to do with this observation. A. E. Meyer

Essential oil and mitosis. B. P. Tokin and A. S. Baranenkowa. *Biol. Zentr.* 50, 633–6(1930).—The division of embryonic cells is stimulated by essential oil from onions. The corresponding observations, as obtained with a mash from onions (*Allium cepa*), may be obtained by the action of the essential oil and not by the supposed mitogenetic irradiation. A. E. Meyer

Enzymic destruction of histidine. Fr. Kauffmann and E. Mislowitzer. *Biochem. Z.* 226, 325–37(1930).—The NH_3 production from histidine by pulp and glycerol exts. from liver of guinea pigs, rabbits, cats and dogs has been studied experimentally, with the general result that the splitting off of NH_3 can be attributed to the action of a desamidase. S. Morgulis

Effect of animal charcoal on glucose in the presence of dehydrating intermediate bodies. Fritz Zuckerkandl and Louise Messiner-Klebermass. *Biochem. Z.* 226, 395–400(1930).—Glucose is not affected if it is heated alone with animal charcoal, but disappears if this is done in the presence of *p*-phenylenediamine or some other aromatic amine, and a difficultly sol. condensation product is formed which is adsorbed on the charcoal. Similarly, glucose is attacked by amino acids in the presence of charcoal. In both cases apparently the amino groups change to imino groups which dehydrate the glucose. It is supposed that in the organism also quinone or imino-forming groups attack the glucose mol. as a first step in the degradation of glucose. S. Morgulis

Studies on the thermolability of enzymes. I. Behavior toward heating of peroxidase extracts purified by ultrafiltration. A. Bach and B. Wilensky. *Biochem. Z.* 226, 482–8(1930).—Reddish peroxidase exts. freed as nearly as possible of non-colloidal components by ultrafiltration are more heat resistent than the original ext. At boiling temp. both the colloidal ultrafiltration residue and the original ext. are equally inactivated but the former regenerates its activity quickly. The degree of regeneration decreases with the duration of the boiling. After 10 min. heating in the boiling water bath the regenerated activity attains a max. after 1–2 hrs. which is only 40% of the original activity, whereas the untreated ext. shows no regeneration at all. The colloidal ultrafiltration residue is irreversibly inactivated only after 5 hrs. heating in the boiling water bath. S. Morgulis

A new enzymic oxidation action (metaoxidase). I. Boas. *Biochem. Z.* 227, 135–9 (1930).—The oxidative enzymes of plants are inactivated by dil. org. or inorg. acids, but on neutralization their activity is restored, but metaoxidase is irreversibly inactivated under similar conditions. Animal products which are rich in oxidases are lacking in metaoxidase. Furthermore while the oxidase and peroxidase contents of various plants are not materially affected by keeping them in 3% H_2O_2, the metaoxidase on the contrary is completely destroyed. The metaoxidase is easily sol. in H_2O, also in dil. alc. or glycerol, but insol. in concd. alc., ether, Me_2CO, $CHCl_3$ or petr. ether. The activity of the enzyme is not destroyed by very dil. acids but is rapidly lost when the acidity is sufficient to change Congo red to blue. Dil. alkalies do not decrease its action. The enzyme is extraordinarily resistant to undercooling. It is distinguished from the phenolases by the following characteristics: The tyrosinase reaction with benzidine is from reddish brown to black (melanin); this change is greatly accelerated by a little H_2O_2. The metaoxidase reaction is rose or cherry-red at the start, becoming gradually darker but never black. Apples, pears, plums, cherries, peaches, apricots or celery give only the metaoxidase but no tyrosinase reaction. Tyrosinase is not taken up either by ether, Am alc. or $CHCl_3$, but the reaction product of metaoxidase after standing with these reagents can be sepd. out by shaking, and they give the characteristic rose or deep red color. S. Morgulis

Method for the preservation and embalming of corpses merely by penetration of antiputrefying gases into the organism without introduction of any liquid in the blood vessels. M. Pietri. *Ann. méd. légale criminol. police sci.* 10, 578–81(1930).—In the Deternitas method, the corpse is placed on a linen mattress which contains 5 kg. of sawdust with 500 g. each of vegetable charcoal, $KMnO_4$, camphor and naphthalene, and which has been sprinkled with 2.5 l. of a mixt. of equal parts of thymol, formalin, alc. and benzoic acid. The coffin is then hermetically sealed. Not only is putrefaction prevented, but even if it has reached an advanced stage, after 3 days all signs of putrefaction have disappeared and the corpse recovers its normal *postmortem* appearance. A. Papineau-Couture

Protein coagulation and its reversal. Improved methods for the reversal of the coagulation of hemoglobin. A. E. MIRSKY AND M. L. ANSON. *J. Gen. Physiol.* **13**, 477–81(1929–30).—Methods are described for the prepn. of sol. cryst. hemoglobin from hemoglobin denatured by HCl or trichloroacetic acid. The yield is about 75%. The coagulation of hemoglobin is probably reversible. C. H. RICHARDSON

Descendence and biochemistry. PAUL KRÜGER. *Biol. Generalis* **6**, 483–570 (1930).—A lecture. More than 2 pages of references are given. G. SCHWOCH

Hypotheses on biological radiations. PAOLO IACCHIA. *Rass. clin. terap. sci. affini* **29**, 66–9(1930). G. SCHWOCH

Intestinal nucleotidase. P. A. LEVENE AND ROBERT T. DILLON. *J. Biol. Chem.* **88**, 753–69(1930).—The comparative rates of sepn. of free phosphate ion from org. combination by means of intestinal nucleotidase of dogs are studied. Hexosemonophosphate, derived from β-diacetone fructose, and glycero phosphate are the most rapidly hydrolyzed, the latter being taken as standard. The amt. of enzyme capable of liberating 1 mg. P as phosphate from glycero phosphate substrate in the first hour is adopted as the unit of activity. This effect is independent of substrate concn. The phosphate is detd. colorimetrically (Kuttner and Cohen, *C. A.* **22**, 606). Uridinephosphoric acid is split as rapidly as many sugar esters (0.8 times the standard rate); adenylic and inosinic acids are split more slowly, and yeast thymonucleic acid is split about 10 times as slowly. Simple acetone pptn. of the intestinal secretion increases the activity 15-fold. K. V. THIMANN

Diastatic activity of honey (LAMPITT, *et al.*) **12**. The sterilization of flour and of enzymes in powdered form (VAN DE VELDE) **12**.

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

The detection of albumose in urine. FRANZ ERBEN. *Wiener klin. Wochschr.* **43**, 1091–2(1930).—Heating with sulfosalicylic acid produces an irreversible ppt. with coagulable protein. A ppt. in the cold which dissolves on heating may be an albumose or Bence-Jones protein. D. B. DILL

Detection of acetone compounds in urine. PH. HORKHEIMER. *Pharm. Ztg.* **75**, 592–4(1930); cf. *C. A.* **24**, 3525.—A review of the more important methods for detecting AcMe, $AcCH_2CO_2H$ and $CH_3CHOHCO_2H$, with some suggestions for carrying out the more promising tests. W. O. E.

A new rapid method for the determination of magnesium with one cubic centimeter of blood, without preliminary elimination of calcium. SHUN ICHI YOSHIMATSU. *Tohoku J. Exptl. Med.* **14**, 29–35(1930).—The Mg is pptd. as Mg hydroxyquinoline complex from deproteinized blood filtrate by addn. of alc. soln. of *o*-hydroxyquinoline. The ppt. is dissolved in HCl and a colorimetric detn. is made with phenol reagent and carbonate soln. as in a phenol detn. L. E. GILSON

Methods for determining the sexual hormone of men. P. DE FREMBERY, J. FREUD AND E. LAQUEUR. *Arch. ges. Physiol.* (*Pflügers*) **225**, 740–1(1930).—The stimulation of growth in the capon's comb by the male hormone is utilized for its quant. estn. ARTHUR GROLLMAN

Absorption ratios of biological stains. W. C. HOLMES AND A. R. PETERSON. *Am. Dyestuff Reptr.* **19**, 689–92(1930).—See *C. A.* **24**, 4314. MILTON HARRIS

Nature of the blood sugar. LEWIS B. WINTER. *Biochem. J.* **24**, 851–5(1930).—The blood sugar of the rabbit was isolated as α-glucose. The proteins are first pptd. by the Folin-Wu reagents, the filtrate is concd. and Pb acetate added. The mixt. is centrifuged, the clear soln. is cooled, made alk. to ammonia and again centrifuged. The treatment with Pb acetate and NH_3 is repeated. The Pb ppt. is washed with 80% alc. and decompd. with 2 *N* H_2SO_4. The material is centrifuged, and 4 vols. alc. are added to the clear soln. The material is centrifuged, the soln. is cooled in ice, and baryta in CH_3OH is added. The Ba compd. is sepd. in the centrifuge, the ppt. is suspended in 80% alc. and decompd. with CO_2. The ppt. is filtered off and the soln. evapd Eighty % alc. is added, insol. material filtered off, and the soln. is allowed to evap. slowly over H_2SO_4. The colorless sirup which is left begins to crystallize on stirring. The crude product is twice recrystd. from MeOH, m. p. 145–146°. Analysis (%): C 39.73, 39.87; H 6.71, 6.64; $C_6H_{12}O_6$ requires C 40.00, H 6.66. The optical activity, mol. wt. detn. and the prepn. of the phenylosazone, as well as the pentaacetate, support the view as to the formula of the substance. BENJAMIN HARROW

Carbohydrate metabolism of normal and tumor tissue. I. A method for the

measurement of the respiratory quotient. FRANK DICKENS AND FRANTISEK SIMER. *Biochem. J.* **24**, 905–13(1930).—The O_2 consumed and CO_2 produced are detd. by readings on the same manometer. The measurement is made on thin slices of tissue, suspended in CO_2-free Ringer soln., buffered with phosphate and in equil. with pure O_2. The CO_2 formed is absorbed by $Ba(OH)_2$. The diminution in pressure which occurs is used for the calcn. of respired O_2. After a definite time an excess of strong acid is added, and the CO_2 is given up from the $Ba(OH)_2$, phosphate and tissue. The resulting pos. pressure is used for the calcn. of the total CO_2 at the end of the expt. This figure, corrected for the CO_2 content at the beginning of the expt., gives the amt. of CO_2 formed in respiration. BENJAMIN HARROW

A sensitive test for cysteine. ROBERT FLEMING. *Biochem. J.* **24**, 965–6(1930).—Cysteine-HCl reacts readily with dimethyl-*p*-phenylenediamine-HCl when heated with $FeCl_3$, giving a deep blue color; the color is stable. BENJAMIN HARROW

Colorimetric determination of cystine by means of the uric acid reagent. CLAUDE RIMINGTON. *Biochem. J.* **24**, 1114–8(1930).—A modification of Folin's method (*C. A.* 23, 4402). To 2 cc. cystine soln., or vol. equivalent to about 1 or 1.5 mg. cystine, add 1 cc. of 20% Na sulfite (Merck's) and wait a min. Add 8 cc. of 3 *N* Na_2CO_3 soln., 5 cc. 40% urea soln., mix and run in 4 cc. of Folin and Marenzi's uric acid reagent. After 5 min. make up to 25 cc. (or 50 cc. if preferred) with 3% Na sulfite (Merck's) soln. and proceed with the colorimetric comparison. BENJAMIN HARROW

Determination of blood sugar. I. Critical analysis of the reduction of alkaline copper reagents by glucose and other substances. SIDNEY L. TOMPSETT. *Biochem. J.* **24**, 1148–63(1930).—The amt. of reduction of the Shaffer-Hartman alk. Cu reagent is greater when carried out in N_2 than in air. When the K salts are not incorporated in the reagent but are added as a sep. soln. after reduction, the reduction is the same in N_2 and in air. The amt. of reduction by glucose of alk. Cu solns. contg. $CuSO_4$, tartaric acid and Na_2CO_3 depends on the relative concns. of the 2 latter substances. Bicarbonates can replace tartrates in alk. Cu solns. Uric acid, creatinine and urea do not affect blood-sugar detns.; but, under certain conditions, glycine, aspartic acid, glutamic acid, tryptophan and cystine do. The modified alk. reagent suggested is (1) $CuSO_4.5H_2O$ 10 g.; tartaric acid 15 g.; Na_2CO_3 (anhyd.) 80 g.; all 3 dissolved in 1 l. (2) Na_2CO_3 (anhyd.) 40 g.; tartaric acid 7.5 g.; KI 10 g.; K iodate 0.7 g.; K oxalate 18.4 g.; all dissolved in 1 l. To run a detn. in a 3 × 1″ centrifuge tube 10 cc. of a protein-free blood filtrate and 10 cc. of (1) are mixed. This is heated in a boiling water-bath for 15 min. It is then cooled and centrifuged. The supernatant fluid is removed and the Cu_2O washed twice with distd. water. Ten cc. of (2) is added to the Cu_2O, followed by 10 cc. *N* H_2SO_4. The whole is well stirred to dissolve the Cu_2O and then titrated with 0.0125 *N* thiosulfate. A blank is run using distilled water. One mg. glucose = 3.3 cc. 0.125 *N* thiosulfate. **II. Effect of different deproteinizing agents upon the estimation of blood sugar.** *Ibid* 1164–71.—By the use of the method suggested above, the sugar content of tungstic acid filtrates is detd. completely. Non-sugar substances present in the filtrates do not affect the results. BENJAMIN HARROW

New method for the separation of the products of protein hydrolysis. MARY AGNES BURNISTON BRAZIER. *Biochem. J.* **24**, 1188–98(1930).—The sepn. is based on the different solubilities of the Cu salts of the amino acids in different solvents. 93.5% of the hydrolyzate from zein was traced. BENJAMIN HARROW

Influence of electric polarization upon the stainability of nerve. K. SATO. *Folia Anat. Jap.* **7**, 33–43(1929); *Stain. Tech.* **5**, 154.—Bethe's method of elec. polarization was used to study the stability of the sciatic nerve of the frog. In the cathodic portion, the stainability was generally weak. Reaction of the dye, unequal distribution of fibrillar acid or the nature of the electrode made no difference. The d. of the tissue at both poles is very important from the standpoint of the phys. theory of staining. At the deep staining anodic portion not only the axis cylinders, but also connective tissue and nuclei were condensed while at the less staining cathodic portion, they were loosened. In general, loose tissue which is fluid will not satisfactorily hold any stain, while those which are compact and poor in fluid do not lose the stain already imbibed. The difference in d. of the tissue at both poles is caused by some vital phenomenon during electrification. The latter is absent in narcotized, poisoned or heated nerves. The difference in stainability is influenced by the intensity and duration of the elec. current, by the nature of the medium in which the nerve prepn. is kept, and by the temp. During the passage through the tissue, K ions travel to the cathode faster than Ca ions. The ratio K/Ca becomes greater than normal, and it decreases at the anode. This may explain why the tissue becomes loose at the cathodic and dense at the anodic portion. K enhances the cathodic effect and makes the difference of d. and stainability

of the tissue more pronounced, while Ca inhibits the effect and minimizes the difference. C. R. FELLERS

Determination and preparation of cystine. Y. OKUDA AND T. KOBAYASHI. *Bull. Agr. Chem. Soc. Japan* **5**, 65–7(1929); cf. *C. A.* **20**, 1094.—The original method proposed by O. for detn. of cystine is compared with the modified method suggested by Teruuchi and Okuda. With gelatin and added cystine, the recovery of cystine by the original method was 99.3–99.9, whereas by the modified method it was 87.8–89.5%. A procedure is given for the sepn. of cystine from hair. The crystn. of tyrosine is retarded in the presence of NH_4OAc at p_H 4.5, whereas that of cystine is not affected. W. D. LANGLEY

Biochemical gravimetric methods. II. Gravimetric determination of potassium on a torsion balance. L. JENDRASSIK AND P. PETRÁS. *Biochem. Z.* **226**, 381–6(1930); cf. *C. A.* **24**, 3527.—K is pptd. as $K_2Na[Co(NO_2)_6].6H_2O$ with the pptg. reagent of de Koninck. The ppt. is collected on a small weighed filter which is dried at 105° and again weighed by means of a torsion balance which has a capacity of 500 mg. To avoid losses of ppt. the edge of the filter is covered with a satd. soln. of paraffin in ether (dild. 1:20 with ether before using). An empirical correction of 0.5 mg. for the paraffin must be introduced. The wt. of the ppt. multiplied by 0.1574 gives the quantity of K. For urine analysis, 5 cc. K-free *N* NaOH is added to 100 cc. urine and this is warmed at 60° for 20 min. to remove NH_3. Neutralized with AcH the urine is placed in a volumetric flask and its original vol. restored by addn. of water. With urines contg. albumin it is advisable to remove this first by pptn. with 1 vol. of 10% Pb acetate and 9 vols. urine. Of the urine so prepd. 4 cc. is used for a detn. The results are accurate to ± 3%. S. MORGULIS

Iodization of peptone. P. BRUNO. *Giorn. farm. chim.* **79**, 308–9(1930).—By heating 360 g. of a peptone (Peptone Terapeutico Società l'Industria di Prodotti Biochimici di Favria) with 100 g. I in 350 cc. H_2O in a water bath B. obtained products which did not contain free I and which were completely sol. in H_2O. G. SCHWOCH

Studies on the plasma calcium-raising principle of bovine parathyroid glands. I. A method of preparation and some observations on the yield, solubility and stability of the product. WILBUR R. TWEEDY. *J. Biol. Chem.* **88**, 649–57(1930).—The glands are extd. 20 min. with 3% HCl at 70°, the filtered ext. is neutralized, treated with cold acetone and pptd. with 2.5% CCl_3COOH. The centrifuged ppt. is dried *in vacuo* at room temp., and extd. with $CHCl_3$ until free from fat. The yield is 1.2–2.9 mg. per gland, of a powder which does not lose activity on storing 8 months, is half inactivated on heating 10 days at 100°, and entirely inactivated by 36 hrs. exposure to a Hg vapor arc, by heating 20 min. at 70° with ½% HCl in alc., or by suspending 1 hr. in abs. alc. satd. with HCl gas at 10°. The soly. in 0.9% NaCl is in some cases increased by suspension in aq. acid alc. and repptn. with Et_2O. The product is sol. in 94% HOAc but not in the anhyd. acid, insol. in (though not pptd. by) pyridine, and 10% sol. in phenol or *o*-cresol. K. V. THIMANN

The determination of inorganic sulfate in serum. ROGER S. HUBBARD. *J. Biol. Chem.* **88**, 663–8(1930).—The method previously described (*J. Biol. Chem.* **74**, v 1927) and modified by Wakefield (*C. A.* **23**, 4239) is given in detail. K. V. T.

The determination of peptic activity; an examination and application of the Gates method of proteolytic enzyme titration. ALFRED GILMAN AND GEORGE R. COWGILL. *J. Biol. Chem.* **88**, 743–52(1930).—The Gates method (*Proc. Soc. Exptl. Biol. Med.* **24**, 936, 1926–7) is developed and given in detail. About 0.5 cc. of the soln. at p_H 2 is placed in a cylindrical cell, made by cementing a ring of Cu wire to a glass square with paraffin, and roofed with a fragment of photographic film developed to a standard opacity. After allowing to digest 10 min. at 25°, the resulting opacity of the film is detd. by a colorimeter, and the peptic activity expressed in terms of the standard, com. pepsin diluted 1:10,000. Ten detns. can be made per hr. The method is best applicable to very high dilns. of the enzyme. K. V. THIMANN

Radiometric microdetermination of sugar (EHRENBERG) 7. Combined use of the photoelectric cell and projection microscope (SAVAGE, JAMIESON) 1.

C—BACTERIOLOGY

CHARLES B. MORREY

A method for the purification of bacteriophage. C. E. CLIFTON. *Proc. Soc. Exptl. Biol. Med.* **28**, 32–3(1930).—Fifty cc. of a suspension of *Staphylococcus* bacteriophage in Martin's broth is stirred for 1 hr. with 50 cc. of a 3.5% suspension of $Al(OH)_3$.

This is collected on a Buchner funnel and washed 5 times with distd. H_2O. The washed alumina mass is stirred for 1/2 hr. with 50 cc. of 0.5% soln. of $(NH_4)_2HPO_4$ and kept at 32° overnight. The alumina is filtered off by suction and the bacteriophage is recovered in the filtrate with but slight loss of activity. The filtrate does not give the ordinary color tests for protein and no ppt. was formed by 1/2 or by complete satn. with $(NH_4)_2SO_4$. C. V. BAILEY

The present status of lactenin. F. S. JONES AND H. S. SIMMS. *Science* **72**, 456–7 (1930); cf. *C. A.* **24**, 1405.—Lactenin is a bacteriostatic substance in milk. It prevents the growth of the mastitis streptococcus for 6 hrs. but after this growth is rapid because of the adaptation of the streptococcus to lactenin. It is assocd. with proteins. The activity is maintained after months in the refrigerator. The lactenin-contg. material in concd. form is quite insol. because of its combination with $Ca_3(PO_4)_2$. Dried prepns. are 200 to 500 times as active as dried skimmed milk. It contains only C, H, O and N. RACHEL BROWN

Some chemical changes accompanying the growth of bovine tubercle bacilli on Long's synthetic medium. ALICE G. RENFREW, KATHERINE M. HARING AND TREAT B. JOHNSON. *Am. Rev. Tuber.* **22**, 116–20(1930); cf. *C. A.* **24**, 137.—Growths of bovine tubercle bacilli, of human and avian tubercle bacilli and of timothy bacilli were followed for a period of 16 weeks. Carbohydrate combinations, as judged by the Cu-reducing properties of the cultures, made their appearance after the third week of growth. The analytical values for reducing sugars after hydrolysis were much higher with bovine bacilli than for avian and timothy cultures, but less than half the value detd. for the human strain, H37. H. J. CORPER

The nature of the growth-promoting principle in the potato in the cultivation of bacteria and especially of the tubercle bacillus. NAO UYEI. *Am. Rev. Tuberc.* **22**, 203–17(1930).—Practically all of the active principles in the potato are to be found in the residue of the potato after its extn. with the common org. solvents, such as acetone, alc. or ether. Investigation of the effects of the various elements known to be present in the potato revealed 2 classes of stimulants for the growth of tubercle bacilli. One class is represented by inositol, maltose and glucose, and is termed metabolic stimulants, because they stimulate the growth of tubercle bacilli only when the bacilli are present in large nos., while the other class of stimulant is represented by sol. starch and dextrin, and is termed reproductive stimulants, because they stimulate the growth of tubercle bacilli not only when these are in large nos., but also in small nos. Glycogen does not appear to possess the property of stimulating the growth of tubercle bacilli *in vitro*, and future studies will be required further to elucidate this. H. J. C.

Do bacteria contain sterols? H. v. BEHRING. *Z. physiol. Chem.* **192**, 112–3 (1930).—Pure cultures of *E. coli* and diphtheria bacilli, which had been cultivated on a sterol-free petone-agar medium, were hydrolyzed and tested for sterols by the usual color reactions and by digitonin pptn. Not a trace of sterol was found. Sterols are therefore not essential to life. They are probably concerned with functions which make their appearance a little higher up in the evolutionary scale. A. W. DOX

Growth of anaerobes in bile media containing malachite green and brilliant green. CHARLES F. POE AND NORMAN F. WITT. *J. Am. Water Works Assoc.* **22**, 1365–73 (1930).—The dyes referred to in concns. greater than 1:100,000 in lactose broth inhibit anaerobic growth, with the exception of *C. welchii* which requires at least 1:20,000 concn. to prevent gas formation. Results are not so good when bile is added. With 5% bile, 1:20,000 brilliant green and 1:30,000 malachite green are necessary and as the percentage of bile increases the inhibition power of these dyes decreases. D. K. FRENCH

The formation of pigment by Bacterium prodigiosum (Serratia marcescens). W. MOYCHO. *Compt. rend.* **191**, 497–9(1930).—This pigment "prodigiosine" is the best known of all bacterial pigments. It has the formula $C_{20}H_{25}N_3O$. M. found that the pigment is formed after the greatest development of the culture. In the first 2 to 3 days, while the bacteria are growing, very little pigment is perceptible, but when the bacteria cease to multiply, prodigiosine is formed. It is apparently formed at the death of the bacteria. This prodigiosine needs for its formation, besides death and autolysis of the cell, the presence of O. M. demonstrates this by removing O from the atm. by means of KOH and pyrogallol and in spite of a great disappearance of bacteria, no prodigiosine is formed. It is also not formed in abundant but young cultures, which have been killed by ether, chloroform or if heated at 70°. However, the addn. of oxygenated water to cultures killed in this way favored the appearance of prodigiosine. F. R. GREENBAUM

Fermentation of rice straw by Bacillus acetoethylicus. VINAYAK NARAYAN PAT-

WARDHAN. *J. Indian Chem. Soc.* 7, 531–6(1930).—Previous work has shown that *Bacillus acetoethylicus* will ferment 2 or 3% pentose solns. forming alc. and acetone, and some formic and acetic acids. In this work, this organism was trained to ferment 7% pentose solns. from hydrolyzed rice straw. In this concn., however, the alc.-acetone yield was too low to make the process practical. In order to train the bacillus to ferment these high concns. it was necessary to include a small quantity of hexose in the medium whenever the pentose concn. was raised. AMY LEVESCONTE

The effect of the initial reaction of Raulin's medium upon the culture of Sterigmocystis nigra. (Preliminary note.) CONSTANTINO LOPARDO, JUAN B. MARGARA AND JOSE DEL VECCHIO. *Ann. farm. bioquim.* 1, 111–8(1930).—*Sterigmocystis nigra* cultivated at 37° in Raulin's medium of reaction from p_H 1.9 to p_H 6.7 produces an increasing acidity in the medium to a max. of p_H 1.8 which it reaches on the third day. The acidity then begins to decrease. B. S. LEVINE

Problems of the nitrogen cycle. II. Further studies on the proteolytic activity of microbes. ALEXANDER JANKE AND HANS HOLZER. *Biochem. Z.* 226, 243–9(1930); cf. *C. A.* 24, 396.—Expts. were made on normal bacteria and molds and those weakened by a previous treatment with $CHCl_3$. It was found that decompn. of casein proceeds more vigorously with normal than with $CHCl_3$-weakened individuals in the so-called liquefying organisms, whereas the opposite effect was noted in non-liquefying organisms. Conclusion: The proteolytic enzymes occur as exoenzymes in the former and as endoenzymes in the latter. S. MORGULIS

The lecithinase of bacteria and the problem of the bacteriolysis of acid-fast bacilli in lecithin emulsions. TADAO TODA. *Centr. Bakt. Parasitenk.*, I Abt., 117, 489–94 (1930).—Many bacteria split lecithin because of the formation of a lecithinase. The lecithinase produced by *Salmonella paratyphi* and *Serratia marcescens* works best at 40°. Its action is not lost when the bacteria are killed by heat. Complete disintegration of acid-fast bacilli by lecithin emulsions was not observed. Probably the loss of the acid-fast property in lecithin emulsions is due largely to the splitting off of fatty acids by the lecithinase. JOHN T. MYERS

Bacteriological contribution to the knowledge of endocarditis lenta. Transformation of Streptococcus viridans into a hemolytic streptococcus. ANNA PINELLI. *Pediatria Rivista* 38, 959–66(1930).—Blood cultures were carried out on a child affected with endocarditis lenta. The examns. on the 58th and 48th day before death revealed the presence of *Streptococcus viridans*, while on the 20th day before death only a hemolytic streptococcus was found. Evidence is presented that the *S. viridans* had been transformed into the hemolytic form. G. SCHWOCH

The pathogenicity of strains of the Löffler bacillus isolated from children affected with diphtheria during the last epidemic. A. SIGNA. *Pediatria Rivista* 38, 1047–57 (1930).—Diphtheria strains were isolated from cases treated in the Pediatric Clinic of the Univ. of Palermo during the epidemic of 1928–9. The detn. of their virulence and toxicity and the comparison of these data with those obtained by Gerbasi in the same institute from cases of the epidemic 1922–3 showed that the pathogenic properties of the strains isolated in 1928–9 are considerably greater than those of the strains isolated in 1922–3. This is perhaps a contributing factor to the increase in fatalities which have resulted from diphtheria during the last few years. G. SCHWOCH

The bacteriological chemistry of the heavy metals. E. A. COOPER AND S. D. NICHOLAS. *J. Soc. Chem. Ind.* 49, 386–8T(1930).—In general Cd compds. are bactericidal. $CdCO_3$ and CdS readily form stable sols, but the phosphate and molybdate do not, while the behavior of Pb salts is the reverse. The bactericidal action of the complex pyrophosphates of the heavy metals with Na was detd. by their effect on the dissolved O absorption of a sewage effluent, as measured by Winkler's method. Na mercurous and Na cadmic pyrophosphates are active in concns. of 1:1,000,000 and 1:10,000, resp. At high dilns. the corresponding Pb compd., and also Pb acetate, crotonate, and maleate definitely stimulate bacterial activity. K. V. THIMANN

D—BOTANY

THOMAS G. PHILLIPS

Nutrient assimilation and growth of buckwheat (Fagopyrum esculentum). A contribution to the t-yield law of higher plants. K. MAIWALD. *Z. Pflanzenernähr. Düngung u. Bodenk.* 17A, 12–42(1930).—The assimilation of nutrients and the formation of matter by the buckwheat were tested in pot expts. The absorption of the N was proportionately more rapid than the total growth of the buckwheat plant as measured by the formation of the total dry matter. The CaO assimilation increased proportionately with the formation of dry matter. However, the assimila-

tion of N had a parallel in the development of some parts of the plant; thus, the formation of dry matter of leaves and roots followed exactly the total N assimilation. With some deviations, the formation of leaf surfaces follows the N assimilation also. Expressed in proportional nos., at 50% of the final dry wt. production, the N assimilation and the development of leaves and roots are about 95% of their maximum; the leaf surface about 80%—or an excess of from 30 to 45% for these growing parts on the basis of the total dry matter at the time. The data for CaO assimilation deviate at most 3-6% of the relative formation of the total dry matter. Except at the point of greatest assimilation, the relative amts. of N assimilation and the amt. of leaf- and root-growth are closely correlated during 10 growing periods. Except for the deviations noted, the hastened N assimilation amounting to 55% and a 15% assimilation of CaO in the stems at one stage the exptl. data of 8 different growth elements of buckwheat show a completely uniform relationship to relative time of growth. The different growth elements are: total dry matter of plant, total N, leaf surface, dry matter of leaves and of roots, N in the leaves and in the stem, and CaO assimilation in the stem. The S-formed curve with relationship to time is obtained. Attempts are made to apply the Robertson growth formulas. R. M. BARNETTE

Studies on the photosynthesis of some plants of Central Asia. S. P. KOSTUICHEV AND E. K. KARDO-SUISOEVA. *Bull. acad. sci. union rép. soviét. social,* Classe sci. phys.-math. **1930,** 467–98.—K. and others have recently (*Planta* **5,** 696(1928)) described a new method for studying photosynthesis, giving the app. used. The results of these studies were expressed in curves where CO_2 assimilated by the leaf is plotted against time, the observations usually extending over a period of 24 hrs. Frequently identical curves were obtained with different eaves, even of diverse species, indicating the indirect influence of external factors. It was shown that most of the results of earlier investigations must be rejected because they were carried out with leaves sepd. from the mother plant. Also it is quite possible that observations were made with leaves taken for study at different points in the daily curve, making comparisons of doubtful value. It was also shown that calcn. of photosynthetic results on a basis of unit leaf surface is inaccurate, and on the weight of the leaf wholly untenable. Moreover, it appeared that in some of the earlier work the leaves were undernourished because of the use of a too slow stream of air, and hence could not develop the complete energy of photosynthesis. The previous expts. of K. and his co-workers were carried out under moderate climatic conditions. As these did not permit the observation of very sharp fluctuations in the daily course of photosynthesis, nor of maximal yields of synthesized products or evolutions of CO_2 in the light, it was thought desirable to carry out similar expts. under more extreme conditions. Central Asia was chosen as a region of typical hot and dry climate. The present results are a direct expression of the analytical data, not depending on any arbitrary modes of calcn., and they were obtained with plants living under natural conditions. With some grasses the CO_2 assimilation amounted to 250 mg. per sq. dm. for 12 hrs., with max. hourly value of 60 mg. Astonishingly sharp leaps in the curves were sometimes observed, with evolutions of CO_2 as high as 25 mg. per sq. dm. and lasting as long as 4 hrs. Grasses, *e. g., Andropogon halenpensis,* in irrigated regions, give enormous daily yields of org. substances per unit leaf surface since with them photosynthesis continues w th great energy in the afternoon hrs. All of the irrigated plants continued working in the afternoon hrs., and a midday decrease was noticed only with the clovers and lucerns. The daily production is very large, and with excess moisture in the soil the plants do not suffer from sun exposure. With xerophytes very sharp fluctuations were observed, gigantic but short-lived flashes of photosynthesis alternating with brief but energetic evolutions of CO_2. With *Cousinia pseudomollis* in the early afternoon hrs. in a period of great sultriness an enormous flash of photosynthesis occurred, giving 60 mg. per sq. dm. per hr. The daily curve for *Alhagi camelorum* shows maxima and unusually sharp transitions from energetic assimilation to energetic evolution of CO_2. With the xerophytes there is also considerable variation from day to day. The causes for the large evolutions of CO_2 in full sunlight have not yet been investigated. Tables of analytical data and curves are given.
LEWIS W. BUTZ

The transfer of the products of photosynthesis. V. A. CHESNOKOV AND E. N. BAZUIRINA. *Bull. acad. sci. union rep. soviét. social,* Classe sci. phys.-math. **1930,** 499–511.—Sachs' method of measuring the energy of photosynthesis by detg. the increase in dry wt. of a given leaf is criticized. C. and B. combine Sachs' method with the direct detn. of photosynthesis in a current of air. The increase in dry wt. was detd. by using not less than 80 half-leaves with an av. area of 300 sq. cm. Photosynthesis was detd. (cf. preceding abstr.) in the daylight hrs., exposures lasting 2–4 hrs. The assimilated CO_2 was calcd. to sugar, and the increase in dry wt. of the re-

maining half of the leaf so estd. The difference gave the value for the transference. Expts. with *Solanum tuberosum* continued over 36 hrs., the change in dry wt. being detd. over 4 hrs. and the figures for photosynthesis were likewise calcd. for this period. The increase in dry wt. continued up till 4–6 P. M. when transference began to exceed photosynthesis The max. assimilation is in the 2 hrs. just before noon, and transference does not appear till the evening hrs. after which it continues all night. The photosynthetic curve has 1 max. With the pea, similar expts. show that assimilation occurs only in the morning, and the ratio between the increase in dry wt. and the intensity of assimilation is less than with the potato. In the pea the photosynthetic max. corresponds to the point of max. transference. Toward evening the amt. of transference decreases, but a small transference continues throughout the night. In the morning it again increases. The cause for the different daily courses of assimilation and transference in the potato and the pea is uncertain. They may be assocd. with the difference in compn. of the leaf carbohydrates, those of the pea being predominantly sol., and those of the potato insol. LEWIS W. BUTZ

A sterol-like compound from the sepals of the sunflower. L. ZECHMEISTER AND P. TUZSON. *Z. physiol. Chem.* **192**, 22–4(1930).—By extn. of 1 kg. of dried sepals of the sunflower (*Helianthus annuus*) with C_6H_6, evapn. of the solvent, extn. of the residue with Et_2O and treatment with KOH in MeOH, addn. of petr. ether and shaking out with 85% MeOH, addn. of H_2O and shaking out with Et_2O, and finally pptn. of the $CHCl_3$ soln. with petr. ether and recrystn. of the ppt. from MeOH, a *sterol-like substance* was obtained in colorless nacreous crystals. The substance has the formula $C_{21}H_{36}O_2$, m. 243°, $[\alpha]_D^{20}$ 40.4°, is unsatd. and gives various sterol reactions, but is not pptd. by digitonin. Its oxidation product with CrO_3 could not be crystd., but yielded a cryst. semicarbazone m. 263° and a cryst. phenylhydrazone m. 210°. A. W. D.

The atomic weight of potassium from plant ash. H. H. LOWRY. *J. Am. Chem Soc.* **52**, 4332–3(1930).—To check the hypothesis of selection of K with an at. wt. of 41 by plants (cf. *C. A.* **24**, 1885) the K:Cl ratios for KCl from the ash of cotton seed hairs and wheat flour were detd. by pptn. with $AgNO_3$. The at. wts. found, 39.111 ± 0.013 and 39.091 ± 0.016, resp., indicated no separation of isotopes by plant growth. L. P. HALL

Studies on hemicelluloses. II. The hemicelluloses of maize cobs. ISAAC A PREECE. *Biochem. J.* **24**, 973–9(1930); cf. *C. A.* **24**, 5480.—Of the four fractions prepd., (1) yields on hydrolysis xylose and a uronic acid; (2) and (3) yield varying proportions of xylose, uronic acid and methylpentose; and (4) yields arabinose, uronic acid and methylpentose. BENJAMIN HARROW

Studies in photosynthesis. I. The formaldehyde hypothesis. EUSTACE C. BARTON-WRIGHT AND MONTAGU C. PRATT. *Biochem. J* **24**, 1210–6(1930).—Klein and Werner's claim (*C. A.* 20, 2519–20) that formaldehyde is the first product of photosynthesis is denied. **II. The first sugar of carbon assimilation and the nature of the carbohydrates in the narcissus leaf.** *Ibid* 1217–34.—Evidence is presented to show that the first sugar of photosynthesis is a hexose and not sucrose. BENJAMIN HARROW

Chemistry of the white rots of wood. I. Effect on wood substance of Polystictus versicolor (Linn) Fr. WM. G. CAMPBELL. *Biochem. J.* **24**, 1235–43(1930).—The pentosans of wood substance and lignin are the first components to be attacked. As decay advances the rate at which pentosans are depleted is diminished, and preferential attack is made on the cellulose proper as well as on the lignin. B. H.

Effect of moisture supply on development of Pyrus communis. ALDEN F. BARSS. *Bot. Gaz.* **90**, 151–76(1930).—Flower clusters were more abundant on trees given more than the min. quantity of water. Abscission of blossoms and partly developed fruits were more pronounced where least water was available. Abundance of water was accompanied by increases in all types of vegetative growth and in length of the growing season. Following changes in the water supply, alteration in the metabolic processes may be due to phys. or nutritional causes or both. BENJAMIN HARROW

The isolation and reactions of a chlorophyllase preparation. HERBERT MAYER. *Planta, Abt. E., Z. wiss. Biol.* **11**, 294–330(1930).—The following method gave a more active chlorophyllase prepn. than that of Willstätter: 500 g. of fresh leaves was ground in 1.5 l. of H_2O together with sand and a small quantity of $CaCO_3$ and the mass was then centrifuged at a high speed for 5 min. The liquor was then poured off and mixed with 2 vols. acetone and allowed to settle after which the soln. was decanted and the residue transferred to a hard filter where it was washed with H_2O-free acetone until the filtrate was colorless. When the residue was dried in a vacuum desiccator, the yield was approx. 15 g. The activity of chlorophyllase was detd. by the addn. of 0.5 g. of the prepn. to 4 mg. of pure chlorophyll in 6 cc. of 66% acetone. Of many kinds of leaves tested *Heracleum* and *Lamium* gave the highest activity, reaching max. values

in May and Sept. and at an optimum p_H of approx. 6.0. After treatment of the leaves with electrolytes, reactivation of the enzyme was obtained by the addn. of 0.1 *M* solns. of alk. and alk. earth chlorides, $KMnO_4$, $ZnSO_4$ and $FeSO_4$, confirming Willstätter's results with $CaCl_2$. Decreased activity resulted with the addn. of $CuSO_4$ but KCN produced complete inactivation. A previous treatment of the tissue with a mixt. of HCl and NH_3 for 2 hrs. allowed of a subsequent treatment with HCl without reducing the enzyme activity. Heating leaf tissue to 60° for 10 min. caused a marked reduction in activity. In variegated leaves the chlorophyllase activity was not proportional to the chlorophyll content. Although leaves grown in total darkness contained less chlorophyllase than leaves in normal light, there was only slightly less in leaves bleached by temporary darkening and no decrease in permanently shaded leaves. A. E. H.

Occurrence of mannitol in spike disease of Santalum album (Linn.). M. SREENIVASAYA. *Nature* **126**, 438(1930); cf. *C. A.* **23**, 3250.—Crystals of mannitol have been obtained from the aq. ext. of the spiked leaf of sandal, in a quantity equal to 2–3% of the green material. Mannitol was found in 15 samples of the diseased plant, but in no healthy samples. The results indicate that mannitol is one of the metabolic products of the virus. LOUISE KELLEY

Aucuba or yellow mosaic of the tomato. BERNARD D. BOLAS AND W. F. BEWLEY. *Nature* **126**, 471(1930).—Infection of tomato plant with aucuba affects the removal of starch from the leaves, the change varying with the stage of infection. B. and B. have suggested a sequence of metabolism based on the results of their study. L. K.

The radium in aquatic organisms. V. VERNADSKII. *Compt. rend.* **191**, No. 10, 421 3(1930); cf. *C. A.* **24**, 3706, 5773.—Expts. show that during the season of max. flowering of different varieties of *Lemna*, the Ra concn. of the surrounding water is negligible while that of the living plant varies from 1.3×10^{-11} to 2.0×10^{-12} parts of Ra per 100 of plant. The decompn. of water by the Ra ceases or diminishes as the Ra from the water is concd. in the plant. N. M. NAYLOR

The production of ethyl alcohol and acetaldehyde by apples in relation to the injuries occurring in storage. I. Injuries to apples occurring in the absence of oxygen and in certain mixtures of carbon dioxide and oxygen. MEIRION THOMAS. *Ann. Appl. Biol.* **16**, 444–57(1929); cf. *C. A.* **20**, 1830.—Under anaerobic conditions, apples suffer from "invasive alc. poisoning," assocd. with an accumulation by anaerobic zymasis of more than 0.3% EtOH in the tissues. CH_3CHO never reaches more than 0.006% in apples showing this type of injury. In gas mixts. contg. CO_2 and O_2 apples undergo CO_2 zymasis at once if the CO_2 concn. > 50%, or in variable time according to the age of the apples if the CO_2 concn. is 20–30%. CO_2 zymasis is usually followed by internal aldehyde poisoning when the CH_3CHO concn. > 0.01%, and by "invasive aldehyde poisoning" when it is > 0.03%. No more than 0.08% EtOH is found in apples suffering from either form of aldehyde poisoning. The injuries are probably caused by CH_3CHO. In mixts. of CO_2 and O_2, CO_2 being about 3% and O_2 concn. subnormal, zymasis does not occur and the life of apples in storage is prolonged. When the CO_2 concn. is between 13 and 20% in such gas mixts. an internal browning (brown-heart) sometimes occurs, the cause of which is not known. As EtOH and CH_3OH poisoning of apples results from improper ventilation during storage, analysis of the apples for these compds. may show whether proper ventilation has been neglected. C. H. R.

The change in composition of winter-cabbage (Brassica oleracea Arephala) during the winter months. ISTVAN WEISER AND VICTOR V. KURELEC. *Wiss. Arch. Landw.*, Abt B, *Tierernahr. Tierzucht* **2**, 422–6(1930).—The leaves and stalks of winter-cabbage were sepd., weighed, chopped and dried and analyses made for ash, crude and pure protein, crude fat, crude fiber, N-free ext. and invert sugar in the leaves and stalks once each month from Nov. to April. There were no significant variations from month to month. S. GORDON ROSE

Effect of radiant energy on growth and sporulation in Colletotrichum phomoides. A. H. HUTCHINSON AND M. R. ASHTON. *Can. J. Research* **3**, 187–99(1930).—A fungus, *Colletotrichum phomoides*, was exposed to ultra-violet radiation and the effects produced were noted. A detn. of the normal growth curve, of the effect of irradiation on growth and the formation of acervuli and on spores suspended in sterile H_2O was made with (*a*) the full light from the quartz Hg light and (*b*) various monochromatic lines of the spectrum from a monochromatic illuminator. The lines of the Hg arc spectrum were found to fall into 3 groups, those which cause const. retardation of growth, those which cause const. stimulation and those which cause primary retardation followed by stimulation. Spore production in general was found to be hastened by the monochromatic light causing retardation or extreme stimulation of growth while light which moderately stimulates growth had little effect on spore production. An optimum duration was shown for the illumination causing the accelerated development of spores. Continued

retardation of growth was shown by the wave lengths 4960–4916, 3028–3022, 2804, 2054 and 1849 A. U. Retardation followed by stimulation was shown by 6152, 3132–3126, 3821, 2700 and 2967 A. U. General stimulation was caused by 5819–5769, 3656–3650, 3342 and 4078–3984 A. U. Wave length 4359 A. U. does not affect the rate of growth appreciably. Yeast and *Paramecium* responded to the effect of irradiation in a manner similar to *Colletotrichum*. J. W. SHIPLEY

Ionic exchange between plant cells and salt solutions. PAUL GENAUD. *Rev. gén. colloïdes* **8**, 241–50(1930); cf. *C. A.* **24**, 879.—A study of the distribution of mineral ions in the living cell and its environment. Expts. carried out on yeast cells showed that pos. ions penetrate easily into the cell, replacing the pos. ions already in the cell according to the law of mass action. Cells are penetrated easily by Pb^{++} and Ca^{++}, and not by Cu^{++}. Bivalent ions penetrate more easily than univalent. Two hypotheses are given: (1) the cell membrane and the cell vacuole behave like insol. org. acids exchanging their cations for those of the environing medium until an equil., due to mass action, is obtained; (2) the cellular membrane is constituted of mols. which are arranged in a certain regular order, so that the intermol. spaces are quite delimited. The results were based on chem. analyses and microscopic examns. of the cells. C. W. SONDERN

Studies on the photosynthesis of marine algae. I. Photosynthetic rates of Enteromorpha linza, Porphyra umbilicalis and Delesseria sinuosa in red, green and blue light. A. BROOKER KLUGH. *Contributions Can. Biol. Fisheries* (N. S.) **6**, Nos. 1-6, 41–63(1930).—The rates of photosynthesis of a green alga from the surface, a red brown alga from half-tide level and a magenta-red alga from 18 m. depth were compared by colorimetric measurement of the p_H change due to the using up of CO_2 (Osterhout and Haas, *C. A.* **12**, 1307) when exposed to sunshine. Corning red, green and blue filters, brought to equal intensity in the active range of the spectrum, were used and the light intensity was reduced to within the range of response of the plant The comparative rates found for *E. linza* were: in the red, 1.80, green, 0.16, blue 1.16; for *P. umbilicalis* 2.46, 1.65 and 1.65, resp., and for *D. sinuosa* 1.35, 1.25 and 1.05, resp. This agrees with the transmission of light by sea water previously detd. (Klugh, *Ecology*, **8**, 90 (1927)). Red is absorbed most and green least, the light at 18 m. depth being almost pure green. K. V. THIMANN

A method for the estimation of the acid-base balance in the ash of plants. DONALD E. FREAR. *J. Biol. Chem* **88**, 675–81(1930).—To 2 g. plant material are added 20 cc. distd. H_2O and 25 cc. of a soln. contg. 25 g. $Mg(NO_3)_2$ per 100 cc. After evapg. to dryness the residue is ashed at 250° for 15 min. and then at 500° for about 30 min., cooled, 60 cc. *N* HNO_3 added and after 3 hrs'. boiling the excess acid titrated with NaOH For the blank 1 g. sugar is used. No S and only a trace of Cl are lost in the vapor The results agree closely with the figures for acid-base balance derived from elementary analysis of the tissue concerned. K. V. THIMANN

E—NUTRITION

PHILIP B HAWK

A contribution to the knowledge of calcium metabolism. II. The relative fecal output of calcium in growing pigs fed exclusively on grain products. A. WESTERLUND *Skand. Arch. Physiol.* **60**, 204–20(1930); cf. *C. A.* **24**, 1145.—A study has been made on the effect on Ca elimination in the feces of the Ca–Si ratio, Ca–fat ratio, Ca–P ratio, Ca–Mg ratio, K–Na ratio, the basic and acid equivs. of the food ash, the Ca consumption and of the wt. of the exptl. animals The study is really a statistical treatment of the exptl. data obtained by Forbes and his co-workers. Conclusion: The limiting factors for the utilization of Ca are a deficiency in Na, P, fat and basic equivs. or of an excess of Si in the animals' food. S. MORGULIS

Blood findings in albino rats suffering from lack of vitamin A. R. G. TURNER *Proc Soc. Exptl. Biol. Med.* **27**, 1006–10(1930).—The amts. of uric acid, non-protein N, creatinine, urea N, chlorides, sugar, hemoglobin and red cells in the blood of xerophthalmic animals are practically the same as those in normal controls. C. V. B.

A note on the effect of the oral administration of irradiated ergosterol on the calcium concentration of the blood serum in pulmonary tuberculosis. JACOB KAMINSKY AND DORIS L. DAVIDSON. *Am. Rev. Tuberc.* **22**, 48–52(1930).—The ingestion of 20 drops of viosterol daily for 7 days was followed by a considerable rise of the serum Ca concn. in patients, and in some cases the higher Ca level shows a tendency to persist for some time after the drug is discontinued. No attempt is made in this study to record observations on the general effect of irradiated ergosterol in pulmonary tuberculo-

sis, but this is reserved for further studies on a larger series of cases. It is believed that in irradiated ergosterol there exists a new means of influencing Ca metabolism, and this may prove of value in pulmonary tuberculosis. H. J. CORPER

Irradiated cod-liver oil and eosin in pulmonary tuberculosis. C. J. HILDEBRAND. *Am. Rev. Tuberc.* **22**, 53–6(1930).—In view of the fact that eosin has been used at various times to enhance the curative effects of ultra-violet light, H. used for treatment in a case of pulmonary tuberculosis irradiated cod-liver oil and eosin with striking beneficial results. H. J. CORPER

Studies on the effect of muscular exercise in beriberi. III. The oxygen debt, oxygen requirement and the changes in respiratory quotient, respiratory volume and carbon dioxide output through muscular exercise. ENAJI HAYASAKA AND ROKURO INAWASHIRO. *Tôhoku J. Exptl. Med.* **14**, 53–71(1930); cf. *C. A.* **23**, 3252.—The O debt is increased. The rise of respiratory quotient during muscular exercise is slight, but becomes very remarkable 5 min. after cessation of exercise, rising considerably above 1. This indicates that non-neutralized lactic acid is accumulated in the exercised muscles during the latter part of the exercise and poured into the blood after cessation, liberating CO_2 from the bicarbonates. In beriberi the CO_2 output during exercise is increased less than in health and this increase returns more slowly to the resting value, so that recovery from fatigue is prolonged. **IV. Influence of muscular exercise on the intermediate water exchange.** ENAJI HAYASAKA. *Ibid* 72–84.—Though in beriberi patients the blood is concd. by muscular exercise, the effect is slighter than in the same patients after recovery or in healthy subjects. The permeability of the capillary walls for serum protein is increased, especially in the dropsical form of beriberi. The swollen tissue is further expanded by muscular exercise, but after cessation it gives up water into the blood profusely and shrinks. **V. Influence of muscular exercise on the lactic acid metabolism.** ENAJI HAYASAKA. *Ibid* 85–92.—The amt. of lactic acid accumulated in the body immediately after muscular exercise is augmented in beriberi. Samples of cubital venous blood showed a max. lactic content about 10 min. after leg exercise (5 min. running in a treadmill). Normal subjects showed analogous results after sufficiently violent exercise. In beriberi the lactic acid resynthesis of the muscles kept quiet during the exercise is apparently decreased after cessation. This is an important cause of the retarded recovery to the resting value. L. E. GILSON

The after-effects of large doses of Vitasterol. W. HEUBNER. *Klin. Wochschr.* **9**, 775(1930); *Bull. Hyg.* **5**, 697.—Contrary to the results of Schmidtmann H. finds no lasting effect of feeding Vitasterol (vitamin D) or any increased susceptibility to spontaneous infections. Rabbits fed on this material lost weight the first month but gained later. They were all killed in good health, but on postmortem examn. showed widespread pathol. conditions in the walls of the arteries. In spite of these findings he claims there are no ill effects of feeding large doses for a short time. G. R. G.

The experimental production of bladder stone in rats. R. MCCARRISON. *Far East Assoc Trop. Med. 7th Congr. India* **3**, 345–6(1927); *Bull. Hyg.* **5**, 699; cf. *C. A.* **22**, 103, **23**, 1956; **24**, 3814.—Diets were principally those of areas where stone is common among the inhabitants of India. The cereal varied from 80 to 100% of the diet. All the diets produced stone except 2 which contained milk to the amt. of $^2/_3$ oz. daily per rat. White flour did not produce stone to any greater extent than oatmeal or whole wheat. This shows that stone is not due to a "toxamin" in the oat meal or whole wheat. The stones were composed of phosphates of Ca and Mg with traces of oxalate, but no uric acid was present. GEORGE R. GREENBANK

Avitaminosis and the digestive system. III. H. E. NEVER AND B. MASSURY. *Arch. ges. Physiol.* (*Pflügers*) **225**, 582–90(1930); cf. *C. A.* **24**, 5801.—Vitamin-free diets contg. no fats produced only slight disturbances in the digestive system of dogs. Considerable digestive disorders resulted when fats were added to the diet. A. G.

The exhaustion of insulin-forming power by carbohydrate overfeeding. F. VERZÁR AND A. VON KÚTHY. *Arch. ges. Physiol.* (*Pflügers*) **225**, 606–12(1930).—Several weeks overfeeding of dogs with sugar resulted in glucosuria, hyperglucemia and a delay in the alimentary hyperglucemic curve. These manifestations of insulin deficiency continued for about a week after the cessation of the carbohydrate overfeeding. A. G.

The effect of the catamenial cycle on the specific-dynamic action of foods. A. SZARKA. *Arch. ges. Physiol.* (*Pflügers*) **225**, 620–6(1930).—The specific dynamic action of food, in the white rat, is a function of the ovarian cycle. It varies inversely with the basal metabolism. ARTHUR GROLLMAN

The effect of the chlorophyll content of the food on blood formation. A. ZIH. *Arch. ges. Physiol.* (*Pflügers*) **225**, 728–36(1930).—Chlorophyll has a decided hematopoietic action when administered to rabbits either alone or in the food. Overdoses

may cause a decrease in the blood cells. When rabbits are transferred to a chlorophyll-free diet, their red-blood-cell count diminishes. ARTHUR GROLLMAN

Heat stability of the (anti-dermatitis, "anti-pellagra") water-soluble vitamin B_2. II. HARRIETTE CHICK AND ALICE MARY COPPING. *Biochem. J.* **24**, 932–8(1930); cf. *C. A.* **24**, 5801.—An ext. made from washed brewer's yeast by boiling in dil. AcOH, after being heated at p_H 2.5 for 4 hrs. at 119° (soln. *a*), retained its power to cure the skin infection in rats due to deprivation of vitamin B_2 when used in doses equiv. to 0.5 g. yeast (dry weight). When the same ext. was heated at p_H 10 3–9.6, no curative properties could be shown. Growth of rats ran parallel with changes in the condition of the skin; growth was restored, with soln. (*a*) but not with soln. (*b*). B. H.

Vitamin C and the rat diet. GLADYS ANNIE HARTWELL. *Biochem. J.* **24**, 967–72 (1930).—Addn. of vitamin C to a synthetic diet shows no improvement as to growth or reproduction. BENJAMIN HARROW

The nutritive value and digestibility of silage from clover. V. A. SKVORTZOV. Trudui Vologod. Molochno-Khozyaistv. Inst., *Bull.* No. **81**, 29–51(1929).—Two cows were put on a test diet for 40 days, divided into 2 20-day periods. The feed consisted of weighed quantities of hay, oat straw, beet pulp, middlings, linseed oil cake and sunflower cake. The unconsumed feed and the manure were carefully collected and samples for analyses taken daily. Fifteen kg. of clover silage was fed daily during the second period. During the second period clover silage increased the digestibility of cellulose by 1.56%, of N-free ext. substances by 1.71%, but it decreased the digestibility of proteins by 3.78%, of albumin by 5.85%, and of fat by 2.36%. The ash constituents suffered the greatest loss in their indigestibility. When compared with green roughage the clover silage gave just as good results. The paper has 11 tables showing the compn of the various materials used in the feeding expts. J. S. JOFFE

An account of the products of exchange in feeding clover silage. M. YA AKSENOVA. Trudui Vologod. Molochno-Khozyaistv. Inst., *Bull.* No. **81**, 55-60(1929).—Addn. of silage to a dairy ration decreased the coeff. of digestibility of nitrogenous substances even though the protein ratio remained the same, for the feed both with and without silage. Apparently the silage stimulates the splitting off of exchange products For this purpose analyses were made on the N exchange products from the manure of exptl. dairy cows fed for 2 consecutive 20-day periods without and with silage, resp. Two g. samples of manure were treated with 1 g. of pepsin in 450 cc. of water and incubated for 48 hrs. After 16, 24 and 48 hrs. 10 cc. of 10% HCl was added. The ppt. was filtered and N detd. It was found that silage feeding increased the quantity of exchange products: epithelial cells, remnants of digestive juices, etc. By recalcg. the digestibility coeff. of the protein when silage was fed with due consideration for the increase in the split products of metabolic exchange it was established that the crude protein from the feed with silage was just as digestible as without silage. A detn. of the acidity of the manure from both—with and without silage—feeding expts. showed no difference. J. S. JOFFE

The calorific value of silage. M. YA. AKSENOVA. Trudui Vologod. Molochno-Khozyaistv. Inst., *Bull.* No. **81**, 63-7(1929).—In connection with the feeding experiments (see preceding abstracts) mentioned the calorific value of the various feeding materials as well as of the manure voided by the cows was determined. The following values (in large calories) were obtained for 1 kg. of dry substance: clover hay—4610.2 clover silage—4678, oat straw—4451.3, beet pulp—4518.8, wheat middlings—4770, linseed meal—5242.9, sun flower seed meal—5312.5. The calorific value of the manure voided in 24 hours was determined for both cows for each period separately; during the first feeding period (no silage) one cow gave off in the form of manure 19393.3 large calories, the other 20757.9 calories; during the second period (with silage) the figures for the corresponding cows were 22009.1 and 22110.3 calories. From the calorific values the coefficients of digestibility have been calculated, as well as the starch equivalent values of silage. The physiologically useful energy per kg. of clover silage was found to be 2426.6 large calories. J. S. JOFFE

Old and new emphasis in the teaching of nutrition. MARY SWARTZ ROSE. *J. Home Econ.* **22**, 878–84, 977–82(1930).—A review. AMY LEVESCONTE

Utilization of milk and inorganic calcium and phosphorus. MYRA T. POTTER AND MARTHA M. KRAMER. *J. Home Econ.* **22**, 923–4(1930).—The food, feces and urine of 2 women were analyzed during 2 three-day periods. In the first period raw milk furnished most of the Ca; in the second period mostly inorg. Ca and P were used, with the butter and acid-washed casein content of the diet increased. The Ca and P were retained equally well in both periods. AMY LEVESCONTE

Studies on diets and nutrition. II. The diet of adolescents from 6 to 15 years of age.

L. DE CARO AND M. LAPORTA. *Arch. sci. biol.* (Italy) **15**, 172–202(1930).—**An analysis** is made of 20 diets given to boys. This is a part of a general investigation, the results of which will serve as a basis for solving the problem of a rational diet for the Italian people. The work is being done under the auspices of the Italian National Research Council. PETER MASUCCI

Vitamin investigations on grass. H. VON EULER AND MARGARETA RYDBOM. *Svensk Kem. Tids.* **42**, 219–23(1930).—A review on vitamins A and D of grass and hay and their bearing on milk and butter. A. R. ROSE

The bone marrow in rachitis and in anemia pseudoleucemia infantum. S. BARBERI. *Pediatria Rivista* **38**, 1089–1111(1930).—The peripheral blood and the bone marrow were examd. in 25 cases of pronounced rachitis, 12 cases of pseudoleucanemia, and 2 cases of leucanemia. In the bone marrow the av. ratios of immature white cells to immature red cells and the av. ratios between immature white cells and mature white cells were (1) in rachitis 1:1.43 and 1:1.68, resp.; (2) in pseudoleucanemia and leucanemia 1:2.97 and 1:2, resp. The histopathological changes, which indicate myelopoietic and erythropoietic hyperactivity, were of the same type in all 3 diseases. B. suggests that rachitis and pseudoleucanemia are probably caused by the same group of factors, *i. e.*, by chronic infections and intoxications. Numerous references are given. G. S.

Experimental studies on a relation between nutrition and growth of transplanted tumor in rats. TOKUJI HIRATA. *Sei-i-kwai Med. J.* **49**, No. 1, 131–46(English abstract 8–10)(1930).—Sixty rats were divided into 4 groups. The restricted diet group (I) was fed with 2 g. unpolished rice, 1 g. vegetable, and 1 drop of cod-liver oil every other day. X-ray group (II) received the mixt. of the same food as (I) but in unlimited quantity and treated with x-ray (75 kv.) for 3–9 min. once or several times until the animals showed a sign of weakening. The cod-liver oil group (III) received the same foods as II, but were not subjected to x-ray treatment. Non-cod-liver oil group (IV) had the same diet as III minus cod-liver oil. After being fed with these diets for 8–12 days, they were inoculated with Flexner strain of rat carcinoma, and continued to be fed with the same diet. The results show that III and IV had more tumor growth than I and II. Conclusion: A poor state of nutrition hinders the growth of transplanted tumor, while a good nutritional state accelerates the proliferation of the tumor cell. S. TASHIRO

Quantitative differentiation of vitamins A and D. II. H. C. SHERMAN AND H. K. STIEBELING. *J. Biol. Chem.* **88**, 683–93(1930); cf. *C. A.* **21**, 2493.—For detn. of vitamin A the amt. of food necessary to produce in young rats a gain in wt. of 3 g. per week is considered to be the best standard. For vitamin *D* the most satisfactory measure is the amt. necessary to produce a degree of calcification midway between the minimum, on diets free from vitamin D, and the max., on diets rich in the vitamin, calcification being detd. by the ash content of the fresh femurs. These units avoid errors due to storage of vitamins in the young rats. K. V. THIMANN

Antirachitic substances. X. The relation of the isoergosterols to vitamin D. WARREN M. COX AND CHARLES E. BILLS. *J. Biol. Chem.* **88**, 709–13(1930); cf. *C. A.* 23, 1163.—The absorption band at λ 248 mμ, ϵ 16,000, previously shown to be common to the several isoergosterols (*C. A.* **23**, 1163) is given by an alc. soln. of ergosterol which has been irradiated until its antirachitic potency begins to decline, and is hence thought to be due to an early degradation product of vitamin D, related to the isoergosterols. Unlike vitamin D, however, the substance is not pptd. by digitonin. K. V. THIMANN

Acid and alkali in health and disease. S. W. CLAUSEN *J. Chem. Education* **7**, 2850–62(1930). E. H.

Interaction between substances in tissue extracts and blood sera. Effects of mixtures of these substances on coagulation of blood. E. L. BURNS, F. H. SCHARLES AND L. F. AITKEN. *Proc. Soc. Exptl. Biol. Med.* **27**, 492–5(1930).—Const. amts. of kidney exts. and blood sera were incubated at 34° for periods up to 80 min., 1 cc. of heparized blood plasma was added and the time necessary for coagulation noted. In controls 0.9% NaCl was used in place of blood serum. Dog, goose and chicken heparized plasma were used and serum and kidney exts. were taken from the human, dog, rabbit, ox, sheep, goose and chicken. Accelerating and inhibiting coagulating substances develop in combinations of sera and exts.; the inhibiting substances are most effective when homologous factors are combined. C. V. BAILEY

Adsorption of glucose-galactose mixtures in the intestine. HARRY SOBOTKA AND

MIRIAM REINER. *Proc. Soc. Exptl. Biol. Med.* **27**, 576–9(1930).—Rabbits fasted 48 hrs. were narcotized with ether, a loop of the small intestine was clamped off and 50 cc. of 10% glucose-galactose mixt. was injected into the loop. Three samples were withdrawn at ½-hr. intervals and analyzed polarimetrically and by Hanes' modification of the Hagedorn-Jensen method. The rate of adsorption from this mixt. was slightly greater for galactose. C. V. BAILEY

Effects of low oxygen pressure on respiratory phenomena. ROBERT GESELL, CHARLES BRASSFIELD, HUGO KRUEGER, HAYDEN NICHOLSON AND MARIE PELECOVICH. *Proc. Soc. Exptl. Biol. Med.* **27**, 849–50(1930).—Eight % O_2 mixts. were given for 30 min. to dogs anesthetized with morphine and urethan; O_2 consumption was at first decreased and later increased to slightly above normal; this increase was probably due to the muscular effort of augmented ventilation, which also caused an abnormal elimination of CO_2. On readministration of room air, ventilation rate and CO_2 elimination decreased; O_2 consumption remained above normal. During the low O_2 pressure period the CO_2 capacity of the blood was at first decreased and later returned to normal or above; similar changes, but to a less degree, occurred in the blood lactic acid. Both during and after the test period the lactic acid of the muscle was greater than that of the blood and still greater than the amt. in the testicle. The H-ion concn. of arterial blood decreased during the test and later increased above the normal level. The results indicate a direct respiratory stimulating action of O_2 deficiency, independent of increased H-ion concn. C. V. BAILEY

Experimentally induced intermenstrual bleeding in ovariectomized monkeys. WILLIAM P. MADDUX. *Proc. Soc. Exptl. Biol. Med.* **27**, 873–4(1930).—Two adult ovariectomized macaques were given intravaginal doses of ovarian hormone ("*amniotin*," E. R. Squibb & Sons) over a period of 12 days; a total of 375 rat units was given to each animal. From the 10th to the 13th day, erythrocytes were in the vaginal contents. The result is attributed to a therapeutic substitution for the endrocrine function of the ovaries. C. V. BAILEY

Excretion of urea in the rabbit at different age periods. K. S. CHOUKE. *Proc. Soc. Exptl. Biol. Med.* **28**, 43–5(1930).—Renal excretion of urea in the rabbit is very low at birth and gradually increases with the advancing age of the animal even when wt. increase is prevented by an insufficient amt. of an adequate diet. Urea excretion varied directly with the protein and amino acids of the diet, as previously detd. by Christman and Lewis (cf. *C. A.* **17**, 3889). C. V. BAILEY

Rate of respiration in erythrocytes. ROBERT RAMSEY AND CHARLES O. WARREN *Quart. J. Exptl. Physiol.* **20**, 213–29(1930).—Erythrocytes, both nucleated and non-nucleated, respire at a rate comparable to that of other resting tissues (30 to 70 cu. mm./g./hr.). The rate of O consumption in the intact animal is probably higher than that found in the expts. The O consumption is temporarily increased upon hemolysis of the erythrocytes by lytic agents because of an increase in metabolism accompanying a liberation of cell contents. The material which respires is not limited to microscopic particles alone, for the Berkefeld filtrate of a hemolyzed red cell suspension shows considerable respiratory activity. RACHEL BROWN

The inhibition of estrus by corpus luteum extracts. J. S. PATEL. *Quart J Exptl. Physiol.* **20**, 245–62(1930).—Kythin inhibits estrus by producing pseudo-pregnancy conditions in the injected mice. The inhibition of estrin can be obtained for a long period (40 days in some cases) without causing any permanent injury to the ovaries Preliminary expts. show that the estrus is prevented by the inhibition of estrin secretion from the ovary whose reactivity to the estrogenic stimulus of the pituitary is reduced but not removed. The response of the vagina to estrin is also slightly reduced. There is no neutralization of estrin by kythin. It is probable that the kythin also acts on the pituitary, inhibiting the secretion of the estrogenic substance of the pituitary, a condition similar to that found during pregnancy. RACHEL BROWN

The endocrine basis of mating in the mouse. B. P. WIESNER AND L. MIRSKAIA. *Quart. J. Exptl. Physiol.* **20**, 273–9(1930).—No mating was observed in untreated ovariotomized mice. Mating was induced in ovariotomized mice by injections of follicular juice and of cornifying exts. prepd. from pregnancy urine. Mating is assumed to be an effect of the cornifying α-factor conditioned by a higher threshold than cornification. RACHEL BROWN

The effect of hyperthyroidism and castration on the serum calcium of the guinea pig. ANATOLE BLINOFF. *Compt. rend. soc. biol.* **103**, 187–8(1930).—The following av. values for Ca (g. per 1000) in guinea-pig sera were obtained: normal, 0.123 (0.100–0.150); castrated, 0.121 (0.096–0.156); hyperthyroid, 0.128 (0.106–0.145); hyperthyroid and castrated, 0.132 (0.106–0.154). B. C. BRUNSTETTER

The effect of hyperthyroidism and castration on cholesterolemia in the dog. ANATOLE BLINOFF. *Compt. rend. soc. biol.* **103**, 188–9(1930).—The av. cholesterol content (g. per 1000) of the blood of 21 normal dogs was 1.75; of 14 castrated dogs, 1.80; of 8 hyperthyroid dogs, 1.23; of 8 dogs, castrated and hyperthyroid, 1.44. Feeding thyroid gland to dogs results in a decrease in blood cholesterol, proportional to the intensity and the duration of the treatment. The decrease in blood cholesterol in dogs, castrated and hyperthyroid, is less pronounced than in hyperthyroid dogs. B. C. B.

The glycogenic reserves of the heart. M. LOEPER AND A. LEMAIRE. *Compt. rend. soc. biol.* **103**, 209–10(1930).—Iodized gum followed by histological examn. was used to study the distribution of glycogen in the heart of the snail, guinea pig, rabbit and calf. Glycogen is found only in quite fresh material. The cells of the bundle zone appear to be glycogen glands, distributing glycogen to the adult fibers of the myocardium. B. C. BRUNSTETTER

The amylase of the heart. M. LOEPER, A. LEMAIRE AND J. TONNET. *Compt. rend. soc. biol.* **103**, 211(1930).—Glycogen in the muscle fibers disappears very quickly after death; the glycogen of the primitive fibers disappears much more slowly. The transformation to glucose is anaerobic. The press juice of 25 g. of cardiac muscle added to 25 cc. of 1% starch paste resulted after 24 hrs. in the formation of 1.46 g. glucose per 1000. The ventricular muscle ext. contains more amylase than exts. of the septa and bundle. B. C. BRUNSTETTER

The alkaline reserve of the horse in the course of successive bleedings. D. BROCQ-ROUSSEU, GALLOT AND G. ROUSSEL. *Compt. rend. soc. biol.* **103**, 212(1930); cf. *C. A.* **23**, 5223.—Successive bleedings are without effect on the alk. reserve of the blood of the horse. B. C. BRUNSTETTER

Regional variations of cardiac lipides. M. LOEPER, J. TONNET AND MLLE. LEBERT. *Compt. rend. soc. biol.* **103**, 321–2(1930).—Cholesterol and total lipides were detd. as parts per 1000 (dry wt.) in the atrioventricular zone (I) and in the ventricular myocardium (II) of the ox-heart. The cholesterol content of I was 12.5, 12.0; of II, 10.75, 9.0; the total lipides content in I was 15, 16.8; in II, 35, 25. B. C. BRUNSTETTER

Regional variations of sulfur in the heart. M. LOEPER, A. LESURE AND J. DE SÈZE. *Compt. rend. biol. soc.* **103**, 322–3(1930).—The right auricle (I), the auriculoventricular septum (II) and the left ventricle (III) were analyzed, the results being expressed in parts per 1000 (dry wt.): total S, I, 4.78; II, 4.90; III, 4.80; neutral S, I, 4.46; II, 4.50; III, 4.44; oxidized S, I, 0.32; II, 0.40; III, 0.36; total protein, I, 53; II, 40; III, 56. B. C. BRUNSTETTER

An excess of serum cholesterol in animals receiving an injection of urine from pregnant women. C. I. PARHON AND MME. T. CAHANE. *Compt. rend. soc. biol.* **103**, 453–4 (1930).—The injection of urine from pregnant women into female rabbits increased the serum cholesterol; injections of urine from non-pregnant women or from males had no effect. B. C. BRUNSTETTER

The distribution of urea in trichloroacetic acid filtrates. E. DELCOURT-BERNARD. *Compt. rend. soc. biol.* **103**, 500–3(1930).—The first portions of filtrates of blood treated with trichloroacetic acid very often have a higher concn. than succeeding portions. The av. difference expressed as a per cent of the min. was 36%. For the detn. of urea by the hypobromite method in urgent cases demanding speed, centrifuging the protein ppt. is recommended. B. C. BRUNSTETTER

The part of the lipides in the refractometric determination of serum proteins. CH. ACHARD, A. GRIGAUT AND A. CODOUNIS. *Compt. rend. soc. biol.* **103**, 679–81(1930).—The detns. of serum proteins by refractometry give higher figures than detns. on the same materials using a gravimetric method (alc. pptn.; cf. *C. A.* **24**, 4315). This difference becomes greater in sera rich in lipides and may amount to 2–3%. B C. B.

A study of the chloride-sodium ratio in blood sera of normal humans. M. LAUDAT AND A. GRANDSIRE. *Compt. rend. soc. biol.* **103**, 683–4(1930).—Detns. of Cl and Na were made on the blood sera of 11 normal cases. The av. Na content was 3.40 g. per l. (3.35–3.50). The av. Cl/Na ratio was 1.10 (1.07–1.13). B. C. BRUNSTETTER

Some facts concerning the reducing substances of the blood. A. BOIVIN AND H. NEBENZAHL. *Compt. rend. soc. biol.* **103**, 695–8(1930).—There is the same amt. of reducing substances within a limit of 10% in filtrates from tungstic and trichloroacetic acid pptns. and in the ultrafiltrate using collodion whether laked blood or plasma is used. In whole blood there are diffusible reducing substances which are pptd. by $Zn(OH)_2$. The ultrafiltrate, either before or after hydrolysis, shows after the action of yeast (which is centrifuged off after 5 min.) a considerable decrease in the amt. of reducing substances not pptd. by $Zn(OH)_2$, accompanied by a notable increase in the

amt. of reducing substances which are pptd. by $Zn(OH)_2$. Yeast can cause considerable changes in the nature of non-adsorbed substances. B. C. BRUNSTETTER

The female sexual hormone. IV. The pure preparation of the follicular hormone from gravid urine. ADOLF BUTENANDT. *Z. physiol. Chem.* **191**, 127–39(1930); cf. *C. A.* **24**, 2783.—With the "crude oil" obtained by extg. the acidified gravid urine with Et_2O or other org. solvents as starting material, the prepn. of the pure hormone involves 4 successive steps. The oil which contains 30,000 mouse units per g. is dissolved in 50% MeOH and extd. with high-boiling petr. ether. As much as 60% of the impurities, including BzOH and cholesterol, are thus removed. The H_2O-MeOH phase is dild. with 3–4 vols. of H_2O and extd. with Et_2O. Evapn. of the Et_2O leaves an oil contg. 1–200,000 mouse units per g. in nearly quant. yield. In the 2nd step this oil is dissolved in 60% EtOH and shaken with C_6H_6. Evapn. of the C_6H_6 phase then leaves an oil contg. 3–500,000 units in 85–90% yield. The 3rd step takes advantage of the lactone character of the hormone. The oil from the C_6H_6 extn. is heated 3 hrs. with dil. HCl in EtOH-H_2O to insure complete conversion to the "neutral" form, and various acid impurities are then removed by shaking with Na_2CO_3. The residual soln. is shaken with NaOH, whereupon the hormone goes into soln. as a Na salt, and the neutral impurities are then shaken out with Et_2O. Addn. of acid now changes the hormone back to its neutral form which is again extd. with Et_2O. The residue from evapn. of this Et_2O ext. contains 1 2,000,000 units per g., yield 75%. The 4th and final step in the purification consists in fractional distn. in a high vacuum (0.02–0.03 mm.), by use of a Hg vapor pump and cooling with MeAc + CO_2. During a slow sublimation over a period of 60 hrs. the crystals collect in the neck of the retort between 130 and 150°. These show an activity of 7–8,000,000 units per g. with a yield of 64%. Recrystn. from EtOAc + petr. ether and finally from EtOAc gives crystals 1–2 cm. long, m. 250–1°, and activity of 8–10,000,000 units. **V. Physical and chemical properties of the crystallized follicular hormone.** *Ibid* 140–56.—The crystd. hormone has a const. m. p. 250–1°, $[\alpha]_D^{18°}$ 156°, absorption max. in the ultra-violet at 283–5 mμ, and empirical formula $C_{18}H_{22}O_2$. It is easily sol. in EtOH, MeAc, $CHCl_3$ and C_6H_6, less sol. in Et_2O and EtOAc and very difficultly sol. in petr. ether. From its soln. in EtOH or MeAc it is pptd. crvst. by H_2O, from EtOAc, $CHCl_3$ or C_6H_6 by petr. ether. One cc. of satd. aq. soln. contains 150 mouse units; hence in 100 cc. there is at most 1.5 mg. of substance. The hormone gives no characteristic color reactions with the usual sterol reagents or with $FeCl_3$. It is sensitive to atm. O, especially in EtOH soln., losing 1/3 of its activity in 2 months and changing into a brown resin. In stoppered containers the solid keeps indefinitely. The activity is 8–40,000,000 mouse units per g., depending on the method of testing. One O is present as OH, the other as ketone. The soly. in alkali, formerly attributed to a lactone structure, is probably due to enolization of the CO group. Treatment with $NH_2OH.AcOH$ yields a cryst. *oxime*, decompg. 230°. The PhNCO deriv. has only 1/4 the original activity, the estrus appearing more slowly and lasting longer. The *Ac deriv.*, m. 126°, prepd. with Ac_2O and pyridine, and the *Bz deriv.*, m. 211–2° (decompn.), prepd. with BzCl and NaOH, have the same activity as the original substance, but the effect is slower and more prolonged, probably because of a gradual hydrolysis in the organism. Catalytic hydrogenation removes O from the CO and saturates 3 double bonds, yielding a *cryst. substance*, $C_{18}H_{30}O$, m. 104°. The structural hydrocarbon, $C_{18}H_{30}$, would contain 8 H less than a satd. paraffin, which might indicate the presence of 1 aromatic nucleus or 4 hydrogenated rings in the mol. A. W. DOX

Fate of choline in the organism. IRVINE H. PAGE AND ERICH SCHMIDT. *Z. physiol. Chem.* **191**, 262–72(1930).—The choline content of serum averages 3 mg. per l., with wide variations for individual sera. When choline is added to active serum and the biol. assay performed immediately, or when added to serum previously heated 0.5 hr. at 56° and assayed after 7 hrs. a loss of 10–20% is observed. If, however, the choline is added to active serum and the assay performed after a lapse of several hrs. the loss is much greater, depending on the concn. and the duration of contact. Addn. of choline to liver press juice or to exts. prepd. from dry powd. liver also resulted in a considerable loss, but here the time factor was of less influence. The loss is not due to an enzyme since it occurs under conditions where an enzyme would be destroyed or would not have time to act. A. W. DOX

The circulatory hormone. VI. The inactivation of callicrein. H. KRAUT, E. K. FREY AND E. WERLE. *Z. physiol. Chem.* **192**, 1–21(1930); cf. *C. A.* **24**, 4541.—The inactivation of callicrein, previously noted when blood serum was added, occurs also on addn. of exts. from lymphatic glands, parotid gland, spleen, liver and spinal cord of cattle, spleen exts. from sheep and goat and human lymph. The inactivator was not

present in any of the other organs examd. A comparison of the properties of the inactivator from blood and that from glands shows some differences which, however, can be traced to other substances accompanying the inactivator in the blood. All inactivator prepns. are destroyed by kinase-free trypsin; hence the inactivator is a polypeptide. Exts. of animal organs contain the inactivator in much greater purity than blood, and the purity can be raised still further by EtOH pptn. Of the purest prepn. 6 γ was sufficient to neutralize the activity of one callicrein unit. Such solns. are therefore especially suitable for the study of the inactivation reaction. The quantity of inactivator required for the inactivation of callicrein depends on the H-ion concn. It is smallest at p_H 8–11, while at p_H 5 no inactivation can be detected. The inactive compd. may be re-activated by acidifying. For detg. the inactivation capacity of prepns. an adjustment to the p_H optimum by addn. of $NaHCO_3$ is necessary. The inactivation is a time reaction, the velocity of which depends on the quantity of inactivator. With a quantity just sufficient the reaction lasts at least 0.5 hr. The equil. of the inactivation reaction at the p_H optimum lies on the side of the inactive compd. However, if a large excess of the inactivator has not been used a small fraction of free callicrein can still be detected. A. W. Dox

Urea formation in the animal body. I. Introduction. S. Salaskin. *Z. physiol. Chem.* **192**, 25–7(1930).—The importance of the problem is pointed out, as also the lack of present knowledge concerning the site of urea formation, precursory substances and fate of the urea itself. The plan outlined for an extensive investigation includes expts. with organ pulp and press juices, perfusion expts. with surviving organs, animal expts. under normal and pathol. conditions and expts. with embryos in various stages of development. **II. Urea formation in surviving organs and in their press juice.** S. Salaskin and L. Soloviev. *Ibid* 28–44.—Autolyzates of liver pulp were examd. with a view to detg. the relationship between urea accumulation and simultaneous arginine cleavage. These detns. show that the total urea formed in liver autolysis under the usual conditions is attributable to the arginine-arginase system. It appears that autolysis of other organs also, under the usual exptl. conditions, results in urea formation by the same process. The curve of urea formation shows an abrupt rise at the start followed relatively soon by a flattening out. The retardation in urea accumulation cannot be attributed to disappearance of the arginase, since the enzyme is present to the very end in the autolyzate, nor to a lack of arginine as a source of urea. It seems to be occasioned either by a weakening of the proteolysis or by impeded splitting off of the residual arginine in the protein mol. The possibility is not excluded that under altered exptl. conditions other substances through the action of other enzyme systems may be sources of urea. A. W. Dox

The significance of saturated sterols in the organism. I. R. Schönheimer, H. v. Behring, R. Hummel and L. Schindel. *Z. physiol. Chem.* **192**, 73–6(1930).—Attempts to convert cholesterol into coprosterol by bacterial putrefaction *in vitro* have thus far been unsuccessful. Nevertheless, it is probable that such reduction occurs in the intestine where conditions are more favorable than *in vitro*. Cholesterol in its natural environment, as *e. g.*, in eggs and brain tissue, was inoculated with fecal matter and incubated 2 months under both aerobic and anaerobic conditions, but the increase in satd. sterols was within the limit of exptl. error. A brief summary is given of the more important results reported in the following papers. **II. Method for the quantitative separation of unsaturated and saturated sterols.** R. Schönheimer. *Ibid* 77–86.—Satd. sterols differ from unsatd. sterols (dihydrocholesterol and coprosterol) in that they give the Salkowski and the Lifschütz color reactions and add I. Where the unsatd. sterols largely predominate in a mixt., neither the colorimetric detn. nor the I no. affords a reliable est. of the amt. of satd. sterol present. The new method is based on the fact that cholesterol forms a dibromide which is not precipitable by digitonin. Since the satd. sterols, as also digitonin, are scarcely attacked by a dil. Br soln., they can thus be detd. practically quantitatively in the presence of a large excess of cholesterol. The sterol prepn. to be examd. is dissolved in 100–120 parts of purest warm 96% EtOH and cooled in ice. An alc. soln. of Br (approx. *N*) is added from a buret during continuous stirring. The Br soln. should be freshly prepd. since it rapidly loses strength, but is more stable if 30% LiBr is added. Br is added until the supernatant liquid over the pptd. bromide has a light yellow color. A large excess must be scrupulously avoided. The pptd. cholesterol dibromide is filtered off on a porous glass filter and washed with cold EtOH. After 1.5–2.0 hrs. an excess of digitonin is added to the filtrate. Since digitonin prepns. which are not quite pure take up some Br, the digitonin soln. may be treated with a slight excess of alc. Br before using, or else a further addn. of Br may be made after adding the reagent. The soln. is kept in the

dark for 48 hrs., then the ppt. is filtered and washed with EtOH and a large vol. of Et_2O. If the cholesterol dibromide is not completely washed out the ppt. becomes brown or black on drying. The digitonide is dried in an oven at 100°, or better *in vacuo* at 60°, and weighed. The presence of 1% dihydrocholesterol in cholesterol is easily recognized. With less than 4% present the error is 20–30%, but above 8% or when the satd. sterols predominate, as in prepns. from feces, the values obtained are almost theoretical. Other unsaponifiable substances do not interfere unless present in large quantity. For detn. of unsatd. sterol the sample is pptd. directly with digitonin and deduction made of the satd. sterol detd. as above. **III. Demonstration and identification of dihydrocholesterol as admixture with body cholesterol.** *Ibid* 86–93.—All cholesterol prepns., com. as well as lab. products, after bromination yield a filtrate from which a ppt. may be obtained with digitonin. This is due to the presence of 1–2% satd. sterol. The amt. remains unchanged even after 10 recrystns. of the cholesterol from EtOH. Mixts. of cholesterol with dihydrocholesterol cannot be sepd. by repeated recrystn., while mixts. with coprosterol show a loss of satd. sterol with each crystn. The satd. sterol was isolated from gallstone cholesterol by bromination of the EtOH soln. in the cold, filtering off the cholesterol dibromide and pptg. the mother liquor with 1% digitonin soln. The digitonide was recrystd. from MeOH and decompd. by boiling xylene. The product thus obtained gave no Salkowski reaction and no oxycholesterol reaction. It was purified by 8 hrs. refluxing with xylene and Na, pptg. with digitonin and liberating again with xylene, and finally identified as dihydrocholesterol, m. 140.5°, $[\alpha]$ 33.54°. Evapn. of the mother liquor from the digitonin pptn., removal of the digitonin by Et_2O extn. and crystn. of the residue from petr. ether, gave ε-cholestanol, m. 168°, an isomer resulting from the rearrangement of dihydrocholesterol. No evidence could be obtained, however, of the presence of coprosterol or its rearrangement product, pseudo-coprosterol. Similar treatment of com. cholesterol, also of cholesterol prepns. from human liver and from beef ovaries, yielded 1–2% of a satd. sterol with the properties of dihydrocholesterol, but no coprosterol could be obtained. **IV. The saturated** [illegible] **sterols from various organs.** R. SCHÖNHEIMER, H. v. BEHRING AND

[illegible] id boiled with 15% HCl in a current of CO_2 or O-free N until they were just dissolved. The soln. was shaken with Et_2O in large separatory funnels and the ext. worked up in the usual way. Each warming or boiling must be done in the presence of an inert gas, otherwise oxidation occurs with development of a dark color which obscures the end point of the bromination. The product should contain no pigmented material except lipochromes which are easily destroyed by Br. The Et_2O extn. from organs dried *in vacuo* and powdered is not quant. Fluids such as bile and blood were treated with NaOH instead of HCl. The total cholesterol was detd. in an aliquot by the digitonin method and the satd. sterols were detd. by the method outlined above. The materials analyzed were com. cholesterol, gallstones, brain, liver, suprarenal, bile, kidney, aorta, large and small intestine, blood and lymph glands. Satd. sterols were invariably found, the quantity varying from 1 to 5% of the total sterol. No organ showed any noteworthy storage. The highest values were obtained with atherosclerotic aorta, where fat masses had for a long time been isolated from metabolic processes. In the living organism satd. sterols are invariably assocd. with the unsatd. sterols. The proportion of satd. sterol is still greater in plants. The sterols from calabar beans, peas and rice contained 6–16% unsatd. sterols. This is to be expected since plants, in contrast to animals, have no means of excreting the satd. sterols and a greater accumulation occurs. **V. Can saturated sterols be absorbed? Remarks on the behavior of the lymph of the thoracic duct during fat and sterol absorption.** H. v. BEHRING AND R. SCHÖNHEIMER. *Ibid* 97–102.—When mice were fed coprosterol or dihydrocholesterol and the carcasses analyzed after removal of the digestive tract, the satd. sterol content was the same as that in the controls receiving normal diet. It was noted incidentally that mice have a much higher satd. sterol content (6–10% of the total sterols) than other animals thus far examd. Another procedure consisted in collecting chyle through a fistula in the thoracic duct of dogs after feeding coprosterol or dihydrositosterol, and analyzing for satd. sterols. The quantity found was altogether negligible. In some expts. the cholesterol present in the chyle was greater than the quantity of total sterols fed, indicating a reabsorption of cholesterol from the bile excreted into the intestine. The sterol of the thoracic duct is the purest cholesterol, with respect to satd. admixtures, thus far isolated from organs. Satd. sterols are not absorbed from the digestive tract. **VI. The excretion of saturated sterols.** R. SCHÖNHEIMER AND H. v. BEHRING. *Ibid* 102–11.—By diverting the feces through an artificial anus the secretion of the cecum was collected and examd. for unsatd. sterols. Dihydrocholesterol

was isolated and identified but no coprosterol was found. It appears that dihydrocholesterol is normally excreted, but unlike cholesterol it cannot be reabsorbed. In the presence of feces the cholesterol thus excreted, as also the alimentary cholesterol, undergoes a bacterial reduction to coprosterol. The same accumulation of unsatd. sterol was found in ovarian dermoid cysts where the quantity in one instance was as great as 77% of the total sterol present. A. W. Dox

The question of ester absorption. Rudolf Schönheimer and Rudolf Hummel. *Z. physiol. Chem.* **192**, 114–6(1930).—To det. whether fats can be absorbed directly through the intestinal wall without first undergoing hydrolysis, a fat or ester should be fed which has characteristic properties capable of recognition in the body tissues, and components which are not alien to the organism. Such an ester is cholesteryl oxalate. Preliminary tests showed that the feeding of cholesteryl palmitate, stearate and oleate to mice results in a storage of these esters in the liver. After a 14-day period of feeding cholesteryl oxalate along with desoxycholic acid to mice the cholesterol content of the livers had increased to 5.34% from the normal value of 0.52–0.67%. However, no trace of oxalic acid could be found after sapon. On the other hand, the urine contained considerable oxalic acid whereas that of the control animals contained none. It is evident that the cholesteryl oxalate first undergoes sapon., then the cholesterol is absorbed and deposited in the tissues, while the oxalic acid is excreted through the kidneys. A. W. Dox

The specificity of sterol absorption, depending on constitution. R. Schönheimer, H. v. Behring and R. Hummel. *Z. physiol. Chem.* **192**, 117–23(1930).—The absorption of various sterols was detd. by feeding the sterol in daily doses of 5 mg. along with 5 mg. of desoxycholic acid to mice over a 15-day period and examg. the liver for increase in sterol content. The plant sterols, sitosterol, stigmasterol and brassicasterol, gave no increase in sterol content of the liver. Of the 3 pairs of isomers, cholesterol and allocholesterol; dihydrocholesterol and coprosterol; ε-cholestanol and pseudocoprosterol, where the isomerism is due to spatial arrangement at C_1, only cholesterol showed unmistakable evidence of absorption. A slight increase in liver sterol after feeding allocholesterol may be attributed to the ease with which the latter rearranges to cholesterol, probably before absorption occurs. The other 4 sterols are satd., and as was to be expected, no absorption occurred. These sterols may be grouped into isomeric pairs in 2 ways, according to differences in configuration at C_1 or at C_4 where the OH occurs. The absorption specificity of cholesterol is quite remarkable. Slight alterations in spatial configuration, and especially satn. of the double linkage, render the substance incapable of absorption. A. W. Dox

The glucolysis of red blood corpuscles. Werner Burger. *Arch. exptl. Path. Pharmakol.* **150**, 298–307(1930).—The rates of anaerobic glucolysis of nucleated and non-nucleated cells are approx. the same; however, acrobic respiration prevents this fermentative process of nucleated cells completely, but only partially prevents that of non-nucleated cells. Although this anaerobic glucolysis is very slow as compared with that of other tissues it is of the same order of magnitude if calcd. on the basis of stroma weight rather than total corpuscle weight. Because young cells are particularly glucolytic, blood glucolysis is higher in pathol. conditions involving blood regeneration: a similar relationship had already been found by Warburg for aerobic respiration. H. Eagle

Comparative investigations of the physiological thermal regulation in increased body temperature following higher external temperature, in fever and in heat stroke. Robert Stigler. *Arch. exptl. Path. Pharmakol.* **152**, 68–90(1930).—A crit. review of the literature. A gradual rise in external temp. is better tolerated than a sudden change: repeated swings increase the efficiency of the regulating mechanism. It has not been possible, however, to raise the body temp. permanently to a higher level by adjusting the external temp. in any species except rodents. The efficiency of the thermal regulating mechanism can be tested by the time required for the artificially induced hyperpyrexia to return to normal. It is because of this that the negro is more resistant to overheating than whites. Exogenous hyperthermia is not endured nearly as well by mammalia (including humans) as the hyperpyrexia of fever (to be discussed in a later paper). The methods employed by rodents to combat exogenous heat are polypnea, vasodilatation in skin, loss of water through lungs, skin and nasal secretion. H. Eagle

Investigation on lactic acid formation in stomach. Franz Delhougne. *Arch. exptl. Path. Pharmakol.* **152**, 160–7(1930).—Dogs' gastric mucosa inflamed by repeated local treatments with C_2H_5OH or $AgNO_3$ can produce as high as 200–700 mg. % of lactic acid from a sugar soln., the amt. being proportional to the time the sugar soln. is left

in the stomach. The excised mucosa can produce lactic acid *in vitro*. The active enzyme may be that of the leucocytes present in the inflamed area. H. EAGLE

Action current of the heart under various mechanical and physiochemical conditions. G. EISMAYER AND H. QUINCKE. *Arch. exptl. Path. Pharmakol.* **152,** 177–84(1930). H. EAGLE

Effect of pancreatic hormone when the physiological passage through the liver is experimentally excluded. F. MEYTHALER AND E. STAHNKE. *Arch. exptl. Path. Pharmakol.* **152,** 185–97(1930).—The pancreatico-duodenal vein is anastomosed to the right renal vein of dogs, following right nephrectomy. By this means the pancreatic secretion passes directly into the greater circulation, without passing through the liver. Abnormally low blood sugar values (50–68 mg. %) are then observed during a 5 months observation period as contrasted with normal values of 0.085–0.110 mg. %. The hyperglucemia following the ingestion of 100 mg. of glucose is minimal, no more than 20–40 mg. instead of the normal 70–100 mg., and is followed by a very pronounced and very long hypoglucemia. Similarly, adrenaline causes a very slight increase. The entire carbohydrate regulatory mechanism is very labile. Very brief periods of hunger, small quantities of insulin or the stimulation of the insulin-app. by ingestion of sugar cause a very marked hypoglucemia; blood sugar may be 0–20 mg. %, without the animals developing any symptoms. Histologically, liver shows an abnormally large glycogen deposition. The somewhat similar results obtained in dogs with Eck fistula would thus be due to direct passage of insulin into the major circulation rather than to partial exclusion of the liver. The absence of adrenaline hyperglucemia in these animals is considered due to an antagonistic action between adrenaline and insulin, both being in the greater circulation, with the insulin apparently more powerful H. EAGLE

Pig stomach fat. JOSEPH S. HEPBURN AND WARREN L. TRESLER. *Am. J. Pharm.* **102,** 569(1930).—A sample of pig stomach was found to contain 4.60% of crude fat or ether ext. A sample of the fat was found to contain the following consts.: I no. (Hanus method) 29.9, sapon. no. 184.3, Hehner no. 90.5; sol. acids 0.06 calcd. as per cent butyric acid, $n_{27.5}$ 1.4663. W. G. GAESSLER

The effect of painful stimuli on the internal secretion of the pancreas and the blood sugar. V. S. SIMNITZKII, A. A. VISHNEVSKII AND S. A. SATVORNITZKAYA. *Arch. ges. Physiol.* (*Pflügers*) **225,** 648–53(1930).—After adrenalectomy, painful stimuli cause a drop in blood sugar. After pancreatectomy, such stimuli cause a hyperglucemia. The reflex arc through which painful stimuli cause these changes consists of the *splanchnic* pathways to the adrenals which mobilize sugar and the *vagal* pathways to the pancreas which stimulate insulin formation. ARTHUR GROLLMAN

The influence of hypophyseal activity by stimulation of the hypothalamus. I. P KARPLUS AND O PECZENIK. *Arch. ges. Physiol.* (*Pflügers*) **225,** 654–68(1930). A. G.

The amylolytic activity of rabbit sputum. E. FISCHL AND R. H. KAHN. *Arch. ges. Physiol.* (*Pflügers*) **225,** 694–8(1930).—The amylolytic activity of rabbit sputum is due to the parotid secretion. Hunger increases the amylolytic activity but prolonged starvation causes a decline in this activity. The amylolytic activity is proportional to the solid content of the saliva. ARTHUR GROLLMAN

The calcium deposit. K. L. SCHNITZER *Arch. ges. Physiol.* (*Pflügers*) 225, 705–10(1930).—The lime deposits of frogs diminished in size after extirpation of the thymus. ARTHUR GROLLMAN

The humoral transmission of impulses from the cardiac nerves. XIII. The distribution of the vagal materials between auricle and ventricle in the frog and mammal. E. ENGELHART. *Arch. ges. Physiol.* (*Pflugers*) **225,** 721–7(1930). A. G.

The effect of the female sexual hormone, menformone, on the plumage of birds. J. FREUD, S. E. DE JONGH AND E. LAQUEUR. *Arch. ges. Physiol.* (*Pflügers*) **225,** 742–68(1930).—Plumage in birds is controlled by the sexual hormone and can be varied by injection of these hormones. Menformone changed the plumage of roosters or male pheasants to that of the hens. ARTHUR GROLLMAN

The relation between the lactic acid content of the blood and fatigue. N. P. RIABUSCHINSKY. *Arch. ges. Physiol.* (*Pflügers*) **226,** 79–85(1930).—Static work, even when continued to exhaustion, does not result in an increase in the lactic acid content of the blood. Dynamic work is essential for its production. Arterial stasis causes an inappreciable increase in lactic acid. ARTHUR GROLLMAN

The respiratory metabolism and body form. E. BRENDLE. *Arch. ges. Physiol.* [illegible] -The respiratory metabolism is relatively greater in small rats than in large ones. It, as well as the sp. dynamic action, decreases with

obesity development. The N content of rats of different sizes is proportional to their wt. ARTHUR GROLLMAN

Urine formation in the frog kidney. XXI. Observations of the cilia in the neck of the tubule. R. HÖBER AND G. ORZECHOWSKI. *Arch. ges. Physiol.* (*Pflüger's*) **226**, 164–70(1930); cf. *C. A.* **24**, 5818.—Ciliary activity in the neck of the tubule is still active despite the cessation of urine formation after poisoning with narcotics or cyanide. ARTHUR GROLLMAN

Oxidation in central and peripheral nervous tissue. ERIC G. HOLMES. *Biochem. J.* **24**, 914–25(1930).—Various types of tissue that compose the central nervous system have different rates of O consumption. The activity of gray matter is greater than that of white matter. The amts. of indophenol oxidase and of cytochrome run parallel to each other. The O uptake of gray matter is increased in the presence of glucose. This is due to the conversion of glucose to lactic acid. If this conversion is prevented by the addn. of fluoride, the increase does not occur. BENJAMIN HARROW

Stability of watery solutions of the oxytoxic principle of the pituitary gland. JOHN H. GADDUM. *Biochem. J.* **24**, 939–44(1930).—The results are summarized in a nomogram which gives the amt. of destruction to be expected when a soln. of any given p_H is heated for any given time at any given temp. BENJAMIN HARROW

Properties of the comb-growth-promoting substance obtained from testes and urine. EDWARD C. DODDS, ALAN GREENWOOD, HAMISH ALLAN AND ERIC J. GALLIMORE. *Biochem. J.* **24**, 1031–8(1930).—The method of measuring comb growth is critically discussed. The max. length of the comb is measured. Besides increase in comb length, another criterion of activity is the development of scarlet papillations on the otherwise dry scaly comb and the simultaneous sloughing off of the dry scales in these areas. Pepsin, trypsin and oxidation destroy the active material, but boiling with acid and alkali does not. The hormone is sol. in benzene, and the benzene soln. may be washed with *N* Na_2CO_3, *N* HCl, and 10% KOH, without, apparently, any loss of potency. When dissolved in 50% alc., the active substance can be completely extd. with light petroleum. The hormone can be distd. in high vacuum, but first it has to be purified and dried. When injected into male castrated rats or mice the atrophied seminal vesicles regain their normal size. The exts. from testes do not produce estrus. BENJAMIN HARROW

Lactic acid oxidation in brain with reference to the "Meyerhof cycle." ERIC G. HOLMES AND CHARLES A. ASHFORD. *Biochem. J.* **24**, 1119–27(1930).—There is no synthesis of carbohydrate from that portion of the lactic acid which disappears but is not accounted for by O_2 uptake. BENJAMIN HARROW

The cause and significance of the decrease of urea in the blood during pregnancy. H. VAN DER HOEVEN. *Nederland. Maandschr. Geneeskunde* **17**, 123–64(1930).—The decrease in urea content of the blood during pregnancy is caused by the existing hyperthyroidism, the thyroid gland stimulating the kidney to such an extent that more urea is eliminated. The urea content can be decreased by giving thyroid ext. During the last few weeks of pregnancy the urea content increases to normal. In case pregnancy lasts longer than 40 weeks the urea content begins to increase during the 38th to 40th week. The emesis and the pregnancy-intoxication are etiologically entirely different. The first is stimulated by a strong hyperfunction of the thyroid, while the second is caused by a deficiency of hyperthyroidism. If, during pregnancy, the urea content of the blood is more than 150 mg. per l., thyroid ext. must be given until the urea content is lower than that amt. As long as the kidney tissue is not damaged, every pregnancy-intoxication as well as abortus can be prevented and cured by administering thyroid ext. J. C. JURRJENS

Investigations on the influence of the sympathicus on the contraction decline of fatigued skeletal muscle. HANS CHARLET. *Z. Biol.* **90**, 299–312(1930). F. K.

Investigations on the mode of action of the sympathetic nerves on striated muscle. EDGARD MICHOL. *Z. Biol.* **90**, 313–26(1930). FRANCES KRASNOW

Glycogen metabolism. WILDER D. BANCROFT AND GEORGE BANCROFT. *Proc. Natl. Acad. Sci.* **16**, 651–7(1930).—Mainly polemical concerning the conversion of glycogen (I) to $MeCHOHCO_2H$ (II) when muscle is contracted, and the reverse reaction during recovery. The main conclusions are: (1) The oxidation and conversion of II are 2 simultaneous reactions and not a coupled reaction. (2) The conversion is a reversible reaction in which enzymes are involved. (3) The equil. is displaced because a stimulated muscle adsorbs less I than does a muscle at rest. (4) Adsorption of I is recovered faster in the presence of O. (5) Cancerous tissue may have lost the ability to adsorb I. This is possibly an accompaniment and not a cause of cancer.

Alc., $CHCl_3$ and other narcotics displace I from proteins and cause the formation of II.
I. M. LEVINE

Investigations on the metabolism of the heart. I. The content of various phosphates in the heart muscle of various animals. KAORU MONONOBE. *Folia Pharmacol. Japon.* 10, No. 1, Opera orig., 13–27(1930)(in German).—Because of discrepancies in the literature on the P content of heart muscle and striated muscle, M. began an investigation to det. the total P and the distribution of the P into inorg., phosphagen and lactacidogen. P expts. were performed on toads, turtles, cats, guinea pigs, rabbits and pigeons. After killing the animals by bleeding, skeletal muscles and the heart were quickly removed, dried from blood by filter paper and P estns. made by the method of Lohmann. In cold-blooded animals during the winter sleep, the phosphagen P content rises, and with the exception of the total P in ventricular muscle of the toad and turtle being the highest, the inorg. P has its lowest value. The lactacidogen P lies midway. Inorg. and lactacidogen P of the heart muscle of turtles and toads shows no variation, whereas the phosphagen P in the toad hearts is greater than that in turtle hearts. The various P contents of toad hearts vary with the season. The inorg. and lactacidogen are increased in summer, but the phosphagen and total P are very much decreased. Skeletal muscle in the same animal shows a far higher P content of various phosphates than heart muscle, but the partition is approx. the same. Pigeon hearts have larger quantities of P than guinea pig hearts, while rabbits have much less. The partition of the P in rabbit, guinea pig and pigeon hearts varies a great deal in these animals. **II. The seasonal variation of various phosphate quantities in heart and skeletal muscle of the toad.** *Ibid* 10, No. 2, Opera orig., 29–38(1930)(in German).—Emden drew attention to the seasonal variation in lactacidogen P in the skeletal muscle of *Rana esculenta* and *Rana temporaria*. These expts. of M. report the monthly variation over 1 year in the various phosphates found in heart and skeletal muscle of toads. Inorg. P averaged about 65 mg. % in heart muscle. The max. amt. is found in July and the min. in February. The same P is max. in skeletal muscle in August and reaches the min. in December. The August value is 170% of the December. The lactacidogen P averages about 77 mg %. Its max. is reached in June and the min. in December (63 mg. %). The max. value is 150% of the min. In skeletal muscle the P reaches its max. in August (117 mg. %), and its min. in December (70 mg. %). The glycogen content in toad liver reaches its highest value in January, but suffers a sudden drop in the next 2 months. After hibernation, the quantity diminishes. The phosphagen P content of heart muscle reaches a max. in January (101 mg. %), and its min. in June (45 mg. %). In skeletal muscle the max. value is found in February and the min. in June. The max. is 230% of the min.
G. H. W. LUCAS

Experimental investigation into the appearance of protein in bile. TSUNEO MATSUDA. *Japan J. Gastroenterology* 2, 130–47(1930).—The liver is injured by CCl_4, $CHCl_3$, toluylenediamine, P, As and alcs. with the excretion of protein in the bile. Org. dyes do not cause protein excretion unless they are very injurious. Protein is also found in the bile after mech. damage to the liver. No protein is produced by satg Kupffer's cells with India ink.
C. M. MCCAY

The influence of the extirpation of the suprarenal capsule on the amylolytic power of the saliva and blood. TULLIO GAYDA. *Arch. sci. biol. (Italy)* 15, 162–71(1930).—As a result of the extirpation of the suprarenal capsule in the rabbit, the amylolytic power of the blood serum increases progressively until death. This increase fits in perfectly with the diminution of such power after adrenaline injections as detd. in previous studies. The amylolytic power of the saliva does not undergo any changes after the extirpation of the suprarenal capsule. The increase in the amylolytic power of the serum following the extirpation of the suprarenal capsule is due to the lack of adrenaline, which normally aids in the emigration of amylase from the blood to the various organs, or inhibits its passage from the organs to the blood.
PETER MASUCCI

The fat of the blood and the fat of the milk during lactation. CH. PORCHER AND L. MAYNARD. *Le Lait* 10, 601–13, 765–82(1930).—A study is reported of the total fatty acids and unsaponifiable matter in the blood plasma of dry and milking cows. These constituents exhibit only small variations from day to day and at different hrs. in the same day. While the values for fatty acids and unsaponifiable matter vary for different individuals, the ratio between them tends to remain const. There is a parallel increase in both these lipides following parturition. Variations of 100% and more frequently occur in the percentage of fat in the milk obtained in consecutive milkings. Despite these large variations the blood lipides studied rarely vary more than 20% and the av. variation is much smaller. No correlation is evident between the per-

centage of fat in the milk and the level of blood lipides at the time the milk is being secreted. L. A. MAYNARD

The surviving liver-pancreas preparation. OSCAR CANTONI. *Biochim. terap. sper.* 17, 325-42(1930).—Blood, after artificial circulation through a liver-pancreas prepn., showed the following chem. changes: higher fatty acids in fasting animals, none, in alimentary lipemia a decrease; in both, the m. p. of the fats is lowered and the I value is increased. The cholesterol decreases. The O is high and CO_2 low; the quotient < 1. The urea increases during the circulation. A. E. MEYER

The hypotensor substance of the pancreas. PIERRE GLEY AND N. KISTHINIOS. *Presse méd.* **38**, 502-3(1930).—The rabbit is not sensitive to peptone poisoning. A mixt. of choline, histamine and peptone produces an increase of blood pressure in the atropinized rabbit in urethan anesthesia. If the peptone is substituted by pancreatic ext. a decrease is observed. The pancreas principle is not identical with peptone. A. E. MEYER

The experimental determination of sex and sexual sterility by means of hormones. B. PANIZZA. *Arch. ital. biol.* **83**, 90-9(1930).—An homologous graft of testicular tissue in not too large an amt. into the peritoneum of a guinea pig previous to impregnation dets. with a great deal of probability the prevalence of the female sex among the new born When the graft exceeds a certain proportion the fetus develops insufficiently or abnormally and the ovary suffers from lesions which are probably responsible for the frequency of abortion and sterility. S. MORGULIS

New investigation of the function of the adrenals. GAETANO VIALE. *Arch. ital. biol.* **83**, 130-6(1930).—Dogs have survived the removal of the second adrenal 18 to 190 hrs. Their blood did not produce any vasomotor response, and did not exert any toxic action. In animals surviving the longest there was a lowering of the alk. reserve of the blood but no change in the p_H. Neither the surface tension, osmotic pressure, protein content, uric acid or Ca concn. show any marked changes, but the viscosity is increased. The hemoglobin content and the no. of red and white cells increase progressively until the death of the latter. The eosinophiles increase particularly. The cholesterol of the blood diminishes while the lecithin always increases. The decrease in the choline content of muscles and cord of adrenalectomized animals is very striking. It is suggested that the medulla of the gland produces adrenaline while the cortex produces choline, 2 antagonistic hormones, so that the adrenal gland has actually a double function. S. MORGULIS

Studies on the assumed occurrence of pulmonary lipodieresis. OSCAR CANTONI. *Arch. ital. biol.* **83**, 154-60(1930).—Expts. on dogs receiving much fat either by mouth or as an intravenous injection fail to give any evidence of the participation of the lung in the fat metabolism. S. MORGULIS

In vitro experiments on the combined peptic-tryptic digestion and the digestibility of certain foods. A. RONCATO. *Arch. ital. biol.* **83**, 180-9(1930).—The curve of peptic digestion with natural foodstuffs has a more or less S-shape somewhat like an autocatalytic curve. The fact that Rona found that the curve was a line with a const. slope of decrement is attributed to the substrate in his expts. which was purified protein The rate of tryptic digestion also when preceded by peptic digestion is greatest with meat. S. MORGULIS

Changes in osmotic pressure of muscle during fatigue and rigor. O. MEYERHOF. *Biochem. Z.* **226**, 1-15(1930).—The lowering of the f. p. of fatigued muscles or of muscles in rigor was detd. by means of a specially designed thermoelectric cryoscope, and these detns. were supplemented with complete analyses of the simultaneous formation of lactic acid and the cleavage of creatine-H_3PO_4, pyrophosphate, and NH_3; also the formation of hexosemono- and di-phosphate esters. In cases of extreme fatigue and rigor the f.-p. depression was about 30% greater than could be accounted for from the known, decompn. processes. S. MORGULIS

Studies on parenteral resorption. V. The resorption of the dye Trypan blue from subcutaneous connective tissue. N. OKUNEV. *Biochem. Z.* **226**, 147-56(1930); cf. *C. A.* **20**, 3466.—Trypan blue does not accumulate in the blood nearly as much after subcutaneous, as it does after intraperitoneal, injection. Probably the rich supply of lymphatics of the diaphragm is more or less responsible for this difference. However, the curves of absorption by either way are remarkably similar and this leads to the conclusion that similar physiol. processes det. both. The subcutaneous resorption of the Trypan blue is definitely influenced by heat, cold, adrenaline or mustard plaster, all of which affect the local blood and lymph circulation. The subcutaneous resorption of the Trypan blue from an inflammatory region shows that this is increased in the initial stage and slowed up in the advanced stage of the inflammation. This

slowing up of the resorption in the core of the inflammation is a protective reaction.
S. MORGULIS

Effect of parathyroid extract on blood phosphatase. IRVINE H. PAGE AND M RESIDE. *Biochem. Z.* **226,** 273–7(1930); cf. *C. A.* **24,** 5363.—Overdosage with parathyroid ext. causes considerable increase in the activity of the serum phosphatase in dogs.
S. MORGULIS

The so-called specific dynamic action of foodstuffs. II. The effect of carbohydrates on the oxygen consumption of isolated cells. Z. HORN AND G. ONODY. *Biochem. Z.* **226,** 286–96(1930); cf. *C. A.* **23,** 4726.—Dextrose, levulose and galactose solns. increase the O_2 consumption of goose erythrocytes but no regular proportionality could be observed between this increase and the concn. of the added glucide. It is argued from this that the specific dynamic effect of carbohydrate in the higher organism is likewise due to a direct action of the foodstuffs on the cells. **III. Effect of blood serum on the oxidation of erythrocytes.** Z. HORN. *Ibid* 297–307.—The O_2 consumption of goose erythrocytes suspensions in Fleisch's soln. is considerably increased through the addn. of mere traces of blood serum, whether of the same or some other species. There is a proportionality between the rise in the O_2 consumption and the amt. of serum added especially in human, rabbit or goose serum, but less markedly so in dog serum. The sugar concn. of the serum used was of no importance in raising the O_2 consumption. The factor in the serum responsible for the rise in O_2 consumption of erythrocytes is thermostable, and is probably a mixt. consisting of dialyzable and non-dialyzable components. **IV. Effect of hormone on cell respiration.** *Ibid* 308–14.—Thyroxine alone or in combination with serum does not alter the O_2 consumption of goose erythrocytes; neither is the effect of serum from thyroidectomized rabbits in any way changed. Insulin alone or in combination with serum has no effect on the O_2 consumption of the erythrocytes, and does not exert any influence on this when it is being increased by means of carbohydrates. The factor in the serum responsible for the increased metabolism of the red cells is therefore neither thyroxine nor insulin. S. MORGULIS

Serum calcium level with special regard to the sexual apparatus of cattle. W. FREI AND MACK A. EMMERSON. *Biochem. Z.* **226,** 355–80(1930).—Calves have a higher serum Ca than fully grown animals, the Ca being somewhat higher in heifers. In cows the serum Ca decreases with age. During estrus the serum Ca is somewhat higher than during the interestrum. The serum Ca curve for an individual cow presents a fall before estrus and a sharp rise during estrus but drops again at its close or soon after. During the corpus luteum phase the Ca rises slightly once more. Pregnant cows have a lower serum Ca than non-pregnant. Castration seems to cause a lowering of the serum Ca in the male but a rise in the female. Cystic degeneration of the ovarian follicles produces an increase in serum Ca. This anomaly is frequently accompanied by nymphomania characterized by a hypersympathecotomy, which is assocd. with an accumulation of Ca both in the blood and tissues. The normal function of the ovary is to lower the Ca content of the tissues, *i. e.*, to produce a vagotonic effect. Nymphomania in cows cannot therefore be regarded simply as the result of ovarian hyperfunction but at most as a temporary hyperoöphoria or perhaps a dysfunction of the germ gland. Injections of progynon produce in cows a lowering of the serum Ca lasting several hrs., whereas sistomensin or anterior hypophysis ext. produces an opposite effect. S. MORGULIS

Influence of Infusoria on the digestion of ruminants. A. VERENINOV, M. AND T VINOGRADOV AND M. DIAKOV. *Biochem. Z.* **226,** 387–94(1930).—The presence of Infusoria in the rumen of the ruminant stomach has an unfavorable effect on the digestion of org. substances, of N and cellulose. S. MORGULIS

The cholesterol content of normal and eclamptic placentas. HELENE GOLDHAMMER. *Biochem. Z.* **226,** 401–3(1930).—The av. cholesterol content of the normal placenta is 0.91% and of eclamptic placentas 0.65% of the dry substance. S. M

Studies on the physiology of the glands. CXXI. Further studies on the function of the thymus. Action of thymocrescin on growth. LEON ASHER AND WIKTOV W. NOWINSKI. *Biochem. Z.* **226,** 415–28(1930); cf. *C. A.* **24,** 5362.—An aq. ext. of thymus, the thymocrescin, is prepd. by the following method: The fresh thymuses from calves, carefully sepd. from adhering fat and connective tissue, are finely cut and extd. with 3 times its wt. of pure acetone for 5–6 hrs. in a refrigerator, the mixt. being stirred frequently. The acetone is pressed out through a fine linen cloth and the residue is dried until all acetone has evapd. The dry residue is extd. 5–7 hrs. with ether in a Soxhlet app., then left under ether for 48 hrs. and again dried until every trace of ether has evapd. The dry residue is rubbed up with 2–3 times its quantity of H_2O and the swollen thymus particles are transferred to a flask contg. 6–8 times H_2O. The extn. is con-

inued for 2–4 days, the extn. is filtered cold, then evapd. in a drying app. at low temp. ntil a greenish slimy mass remains. Subcutaneous injections of an amt. correspond- ng to 20 mg. dry substance are entirely non-injurious and prevent the loss of body vt. for 14 days of rats on a vitamin-free diet or may even occasion a new rise in wt. f added directly to the vitamin-free diet, the thymocrescin soln. may occasion at first, or a considerable time, a vigorous growth. **CXXII. The iron metabolism of normal nd splenectomized animals under the influence of reduced pressure.** LEON ASHER ND RUDOLF KALBERMATTEN. *Ibid* 429–40.—In normal guinea pigs the Fe excretion s somewhat higher when the animals are maintained at a low pressure. Following plenectomy the Fe excretion under the reduced pressure is markedly increased, and his may persist for a long time or the Fe excretion may gradually readjust itself. These acts support the view that the spleen is an organ for Fe metabolism; furthermore, hat under the demands of the lowered pressure other organs may compensate for the pleen in regulating the Fe excretion. **CXXIII. Electrolyte exchange between tissues nd blood under the influence of specific diuretics. A contribution to the study of liuresis** LEON ASHER AND WERNER RIESEN. *Ibid* 441–56.—A method has been de- ised to perfuse the entire mass of intestines of the frog, with the nerves intact, the eart acting as the motor force. The perfusion with 3% gum arabic and 20% serum an be maintained for hrs. without causing the least edema. The addn. of a specific luretic to the perfusing fluid caused an increase in the electrolyte content of the per- usate. It was also found that in animals with the innervation intact the electrolyte ncrease in the perfusate was 1½ times as great as in the absence of the innervation. Conclusion: The diuretics act directly on the tissues and their effect depends largely n the vegetative nervous system impulses. S. MORGULIS

The effect of irradiated ergosterol and of parathyroid hormone on tissue phospha- ases. WALTER HEYMANN. *Biochem. Z.* **227**, 1–5(1930).—The glycerophosphatase nd the hexosediphosphatase of bones are inhibited in their action *in vitro* to a much reater extent than the phosphatases of kidney or intestine. Under the influence of rradiated ergosterol, the phosphatase activity *in vitro* is unchanged; ultra-violet radia- ion has caused inhibition of the enzymes in about 40% of the tests; while parathormone nhibited the activity of both enzymes of the bone epiphyses. S. MORGULIS

Glucolysis and phosphoric acid production in the red blood cells of different species. W. A. ENGELHARDT AND M. LIUBIMOVA. *Biochem. Z.* **227**, 6–15(1930).—Cleavage of H_3PO_4 compds. is a const. occurrence in erythrocytes. Glucolysis is accompanied by new formation of H_3PO_4 compds. According to the extent of H_3PO_4 cleavage the rythrocytes of various animals arrange themselves in the following series: cow < goat, orse < dog, pig < man, guinea pig < rabbit, which corresponds in general to the inorg. P content (except the pig). According to their glucolytic ability the cells are arranged n this series: cow < goat < horse < guinea pig < man < rabbit, so that a close simi- arity between the 2 can be noted. The pig erythrocytes again are an exception be- ause they do not glucolyze at all. The coeff. of mols. found H_3PO_4/mols. sugar dis- ppearing varies for different animals. For the goat, cow and horse it is 0.2 0.3; for nan, dog, guinea pig and rabbit it is 0.5–1.0, the latter being evidently a limiting value. S. MORGULIS

Ortho- and pyro-phosphate in the aerobic and anaerobic metabolism of the red blood ells. W. A. ENGELHARDT. *Biochem. Z.* **227**, 16–38(1930).—Non-nucleated erythro- ytes can be changed to a predominantly aerobic metabolism under the influence of nethylene blue. When the residual glucolytic power is depressed by NaF considerable uantities of H_3PO_4 become organically bound in the methylene blue respiration. Re- ression of the respiration of nucleated bird erythrocytes leads to a quick increase in norg. H_3PO_4, which is not the result of induced cleavage of H_3PO_4 compds. but of a ailure to resynthesis which respiration normally induces. The pyrophosphate is con- idered the most important source of the H_3PO_4. It is assumed that the cleavage of H_3PO_4 proceeds continuously in the cells, even under aerobic conditions, but that res- iration holds back the hydrolytic process, as can be demonstrated directly by the erobic resynthesis of pyrophosphate following its anaerobic cleavage. This is sup- osed to be a phenomenon common to all cells. S. MORGULIS

Does lactacidogen (hexosemonophosphoric acid) decompose during muscle con- traction? K. LOHMANN. *Biochem. Z.* **227**, 39–50(1930).—The decompn. of lactacido- en in the course of a single twitch has not been demonstrated, though the Embden hexosemonophosphoric ester may be lactacidogen in the sense that it *can* produce lactic cid. The only doubtful point is whether in muscle contraction this ester *must* be the source of the lactic acid. S. MORGULIS

Further studies on muscle contraction without lactic acid formation. EINAR

LUNDSGAARD. *Biochem. Z.* **227**, 51–83(1930); cf. *C. A.* **24**, 1899.—*Muscles poisoned with monoiodoacetic acid do not produce lactic acid during contraction. Phosphagen hydrolysis is definitely related to the work done in a single twitch or in tetanic contraction.* Curarization of the muscle poisoned with monoiodoacetic acid does not alter these values for phosphagen hydrolysis; likewise the chronaxy of the poisoned muscles is normal and is altered by curare exactly as it would be in a normal muscle. However, following the monoiodoacetic acid poisoning the anaerobic resynthesis of the phosphagen does not take place. Muscles only moderately poisoned performed more work with a smaller diminution in the phosphagen content in O_2 than in N_2, so that oxidative phosphagen resynthesis must have occurred. There is no evidence that pyrophosphate was hydrolyzed during work and development of rigor. S. M.

The change in reaction of active muscle. F. LIPMANN AND O. MEYERHOF. *Biochem. Z.* **227**, 84–109(1930).—By means of the manometric method it is shown that under anaerobic conditions the muscle reaction is so altered as would be expected from the creatine-H_3PO_4 hydrolysis, on the one hand, and from lactic acid formation on the other. This effect is also modified somewhat by NH_3 formation, esterification, etc. For this reason during the early part of anaerobic fatigue in the presence of a high CO_2 tension there is a gradual alkalinization followed later by an acidification In muscles poisoned with monoiodoacetic acid there is only alkalinization which reaches a max. value and remains unchanged. But in both normal and poisoned muscles the alterations in the acid-base equil. corresponds with those calcd. from the changes of the CO_2 pressure. S. MORGULIS

The metabolism of the acting, fluoride-poisoned muscle. F. LIPMANN. *Biochem. Z.* **227**, 110–5(1930).—When frogs, *Rana temporaria*, are poisoned by a sufficient NaF injection to give a concn. of about 0.025 *M* the muscles contract with a greatly diminished production of lactic acid. The effect is similar to that of the monoiodoacetic acid, although unlike this the action of the NaF develops at once and is reversible. In these NaF-poisoned muscles there is an increased decompn. of phosphagen, hydrolysis of adenylpyrophosphoric acid and extensive esterification of hexose with H_3PO_4. The poisoned muscles become rigid after a few contractions. S. MORGULIS

The metabolism of the acting carbohydrate-poor cold-blooded muscle. SEVERO OCHOA. *Biochem. Z.* **227**, 116–34(1930).—The carbohydrate metabolism of muscles from frogs made glycogen-poor with insulin was compared with their tension capacity both in O_2 and N_2. The muscle made practically carbohydrate-free by insulin cannot completely cover the tension work performed through the oxidation of carbohydrate Under these conditions the anaerobically produced lactic acid corresponds to the carbohydrate still present. The phosphagen hydrolysis is then relatively large, but there is no satisfactory evidence that the energy not accounted for by lactic acid formation is derived from the phosphagen cleavage. S. MORGULIS

The catalytic action of blood hemins and chlorophyll hemins. OTTO WARBURG AND FRITZ KUBOWITZ. *Biochem. Z.* **227**, 184–99(1930).—Rabbit red cells, washed with 0.9% NaCl and suspended in a mixt. consisting of 8.5 vol. *M*/2 Na_2HPO_4 + 1.5 vol. *M*/2 KH_2PO_4 + 24 vol. 0.9% NaCl, were used to det. the O_2 consumption. One cc. of the suspension glucolyzes 0.17 mg. glucose per hr. at 38° aerobically and about 0.25 mg. anaerobically. The respiration is completely stopped by 0.001 *N* HCN The addn. of spirographis- or copro-hemin had no effect and that of ordinary blood hemin had a small effect. Pyrrohemin agglutinates the red cells in salt soln. but not when they are suspended in isotonic glucose soln. It raises the O_2 consumption of the cells, especially in the presence of glucose but the respiratory quotient shows that the glucose is incompletely oxidized to pyruvic acid. The pyrrohemin respiration is strongly inhibited by CO both in the light and in the dark. Another chlorophyll hemin, the pheophorbid- a-hemin, accelerates the respiration of the red cells about 20 times but in the absence of glucose its effect soon wears off. Its effect is inhibited by CO very much as in the case of the pyrrohemin. The hemins cause the formation of methemoglobin in variable amts. even when acting on intact red cells, and this formation is stimulated by HCN. The methemoglobin causes the oxidation of glucose whereby its tervalent Fe becomes bivalent Fe. However, there is no definite relationship between the catalytic effect of the hemins and their methemoglobin formation. The idea of a catalytic mechanism is developed according to which the autoxidizable Fe of hemin reacts with O_2, being converted to Fe^{+++} which reacts with the non-autoxidizable Fe^{++} of hemoglobin. S. MORGULIS

Studies on blood sugar. II. P. RONA AND W. FABISCH. *Biochem. Z.* **227**, 205–20 (1930); cf. *C. A.* **24**, 1899.—New exptl. evidence is adduced to show that the normal blood sugar in man detd. by the Hagedorn-Jensen method is about −4% the same as

when detd. gasometrically by the fermentation procedure with *B. coli*. The same correspondence was observed in the blood sugar detns. by both procedures in adrenaline hyperglucemia in rabbits. In human diabetics there were in some instances differences which could not be attributed to methodical errors. In hypoglucemic shock in the rabbit the blood sugar values by the Hagedorn-Jensen method were invariably too high as compared with the same by the fermentation procedure. S. MORGULIS

Determination of the catalase content of blood. E. BACH. *Biochem. Z.* **227**, 221–9(1930).—It is pointed out that in dild. blood the catalase must be detd. soon after the removal of the blood, otherwise one should use defibrinated blood. To avoid the destruction of the catalase by the H_2O_2 a very dil. soln. should be used, and the p_H equilibrated through the use of buffers. The monomol. equation is employed in calcg. the relative amt. of catalase. S. MORGULIS

The putrefaction and reduction of sterol with special reference to the conditions in the intestine of the infant. GEORG BISCHOFF. *Biochem. Z.* **227**, 230–6(1930); cf. *C. A.* **24**, 4825.—Even on a pure milk diet there is considerable reduced sterol in the feces which runs parallel to the clinically observable intestinal putrefaction. Small quantities are found also in the stool of breast-fed infants or in other non-putrefactive stools, but in this case the substance is dihydrocholesterol and not coprosterol. Of course, in babies on a milk diet with putrefactive stools the amt. of coprosterol is never as high as on a meat diet. Coprosterol is evidently not absorbed. S. M.

The influence of thymus on growth and the preparation of an active thymic substance, the thymocrescin. LEON ASHER. *Endokrinologie* **7**, 321–7(1930).—The prepn. of thymocrescin is described which stimulates vigorously the growth of young rats on a deficient diet. It affects the Ca metabolism. S. MORGULIS

Distribution of iodine in normal and in iodine-treated hyperthyroid thyroid glands. Studies on iodine metabolism. IV. GULBRAND LUNDE AND K. WÜLFERT. *Endokrinologie* **7**, 327–63(1930); cf. *C. A.* **23**, 3270.—The I_2 of the thyroid gland consists of 3 fractions: a water- and acetone-sol., a water-sol. acetone-insol. and a water-insol. fraction. The water-sol. moiety is probably inorg. I, but it is possible that it is formed only postmorten or in the process of prepn. The acetone-insol. fraction is a protein iodide compd. and is the active substance of the thyroid. In preoperative treatment of primary thyreotoxicosis with Lugol's soln. the colloid-rich, I_2-poor gland is transformed into one poor in colloid and rich in I_2, while at the same time the blood also becomes richer in the protein-iodide content. The preoperative treatment, however, does not enrich the gland with the protein iodide compd., at any rate not sufficiently to bring this up to the normal, and in fact the protein-iodide content still remains far below that of normal glands. In cases which have been treated for many months with Lugol's soln. the I_2 distribution in the gland is almost normal, although these patients still show the clinical picture of severe thyreotoxicosis. In 2 cases of thyroid cancer the I_2 content, especially the water-sol. protein-iodide fraction, was greatly diminished. It is suggested that perhaps a chem. analysis of the gland in addn. to the histological examination may be essential for diagnosis. Continuous fever apparently also causes a rearrangement in the I_2 distribution, the water-insol. fraction generally increasing very much under this condition. S. MORGULIS

Studies on the physiology of pregnancy. KARL V. FEKETE. *Endokrinologie* **7**, 364–9 (1930).—Pregnancy serum can so modify the chem. structure of the hormone of the posterior hypophysis lobe that it will no longer stimulate the contractions of the gravid uterus. Especially in the last 2 months of pregnancy is the effect of the serum great, 1 cc. being sufficient to inactivate 0.5–0.6 Vögtlin units of Glanduitrin. At the same time it is also found that the gravid uterus undergoes such alterations that its musculature no longer responds to the posterior pituitary hormone which has been acted upon by the pregnancy serum. S. MORGULIS

The cystine and cysteine content of human hair. TETSUTARO TADOKORO AND HANAKO UGAMI. *J. Biochem.* (Japan) **12**, 187–93(1930).—The cystine content of the terminal part of the hair is lower than that of other parts. It is also less in the hair of young men with powerful growth than of old men. But while the cystine content varies with age, the cystine/N ratio is practically const. The melanin content of black hair is much greater than that of white hair, and the black hair also has a high cystine and low N content. The cysteine–cystine ratio is higher in the hair of young men than in hair from old men. Also it seems that the hair of young people contains glutathione which is scant in the hair of older people. S. MORGULIS

Biochemical studies on the auriculo-ventricular junctional system of the heart. II. The metabolic activity. KAGEYU YAMAZAKI. *J. Biochem* (Japan) **12**, 223–34 (1930); cf. *C. A.* **23**, 4737.—The auriculo-ventricular junction of the heart shows a

higher dehydrogenase and oxidase activity than the rest of the heart muscle. Its sulfhydryl content is lower, and it consumes less O_2 than the heart muscle. All this indicates that the metabolic activity of the Tawara bundle is inferior to that of the heart muscle. **III. The phosphatide and cholesterol content.** *Ibid* 235–9.—The auriculo-ventricular bundle of Tawara of the ox heart has a lower phosphatide content than the heart muscle, while the cholesterol content is very nearly the same for both. **IV. Studies on the anaerobic oxidation of the auriculo-ventricular system.** *Ibid* 241–6.—The auriculo-ventricular bundle of the heart is very resistant to cyanide, and can still consume to a certain extent O_2 when poisoned with $M/2500$ KCN. The bundle continues its automatic contraction in Locke's soln. free from O_2. S. M.

The alcohol content of the blood under different conditions. P. I. Tuovinen *Skand. Arch. Physiol.* **60**, 1–134(1930).—The exptl. subjects consumed usually 60 cc. alc., except one subject who only took 40 cc. doses. The blood alc. concn. of the same person even under uniform conditions is not the same, though following the consumption of alc. the variations are more regular in nature. If alc. is taken with food the blood alc. concn. becomes much lower than when taken on an empty stomach. Also, if alc. is taken during or after a meal it causes a slower rise with a lower final level in the blood alc. concn. than if taken before the meal. Furthermore, a mixed meal inhibits the effect of consumed alc. on the blood alc. concn. more than a meal of the same caloric value but consisting of either protein, carbohydrate or fat alone. The latter is particularly ineffective. The consumption of dil. alc. (5 to 20%) produces a greater rise in the blood alc. concn. than stronger alc. solns. of 40 and 60%. However, an hr. later the effect of the stronger alc. solns. upon the blood alc. level is often greater than that of the more dil. solns. The strength of the alc. soln. affects the blood alc. concn. even in the presence of food. The sensation exerted by alc. is proportional to the strength of the alc. soln. and although subjects vary in this respect the initial sensation appears when the blood contains about 0.006 to 0.010% alc. In general, this sensation is greater after the consumption of dil. than of strong alc. solns S. M.

Survival of the dried isolated salivary gland. O. V. Nikolaev. *Zhur. exptl Biol. Med.* **13**, 126–30(1929).—The isolated salivary gland of the dog can be restored to functional activity by soaking in and perfusing with Ringer-Locke soln. even after the gland had lost 75% of its wt. through desiccation. The secretory cells and the vessels react to electrolytes, $CaCl_2$ and KCl or poison like nicotine as they did in the fresh gland, though not as energetically. The blood vessels are, however, more resistant than the secreting tissue. S. Morgulis

The mechanism of the transformation of pyruvic acid to lactic acid in the liver. Mme. Y. Khouvine, E. Aubel and L. Chevillard. *Compt. rend.* **191**, 446–8(1930) cf. *C. A.* **24**, 5353.—Expts. to det. the influence of pyrophosphate upon the transformation of pyruvic acid to lactic acid in liver were carried out as follows: Hashed liver was suspended in Ringer soln. Sep. digestion tests were made in the presence of Na pyrophosphate, Na pyruvate and both in the same test. The digestion took place at p_H 7.4, 39°, for 4 hrs. It is shown that the pyrophosphate favors the reduction of pyruvic acid by the formation of more lactic acid. (This confirms the work of Warburg.) Na pyrophosphate decreases the CO_2 formed in the digestion test of liver with Na pyruvate. It decreases very slightly the consumption of O. In aerobic expts. without pyrophosphate, if the CO_2 due to pyruvate is suppressed, the same ratio of lactic acid to CO_2 was found as in these expts., which shows that lactic acid is formed directly by reduction of pyruvic acid. The work indicates that the reaction is not due to a xanthine-oxidase of the liver but to some enzyme which helps pyruvic acid to accept H. N. M. N.

Assimilation of starch and the formation of glycogen by rumen Infusoria. Filippo Usuelli. *Wiss. Arch. Landw.*, Abt. B, *Tierernähr. Tierzucht.* **3**, 4–19(1930); cf. *Z vergleich. Physiol.* **4**, 305(1926).—The contents of sheeps rumen were placed in a thermostat at 37°, rice, corn, potato and wheat starch were added, and the percentage of the Infusoria contg. starch and glycogen was detd. by fixation with formalin, imparting an I_2 color with Lugol soln., and counting the Infusoria by means of a Zeiss counting chamber (cf. *Z. Tierzücht. Züchtungsbiol. Tierernähr.* **12**, 31(1928). Starch assimilation attains a max. in 4 hrs., glycogen formation in 6 hrs. Different starches gave widely different max. values, which were shown to be due to differences in the size of the starch grains. Similar detns. were made on the contents of the sheeps rumen after feeding starch to the sheep. This expt. gave higher max. values than those obtained in the thermostat. W. Gordon Rose

Normal variations in the calcium content of the blood of dairy cattle. L. S. Palmer and C. H. Eckles. *J. Dairy Sci.* **13**, 351–9(1930); cf. *C. A.* **24**, 4827.—A biometric study was made on 60 sets of blood samples, each set representing 3 consecutive days.

taken from 24 cows at monthly intervals over a period up to 4 months. Considered as a whole correlation coeffs. are fairly high but they are decidedly lower than those for the inorg. P of the same samples. There are marked day to day variations which are due to an undetd. cause. F. L. SEYMOUR-JONES

The biometry of calcium and inorganic phosphorus in the blood plasma of dairy cattle. Application of results to bone mineralization. L. S. PALMER, R. A. GORTNER AND RACHEL RUDE. *J. Dairy Sci.* **13**, 360–7(1930); cf. preceding abstr.—A study of the available data for dairy cattle shows that while fair to high correlation exists between the Ca and phosphate of the blood plasma on successive days, no correlation exists between the Ca and inorg. phosphate. "No biologically significant amt. of Ca phosphate occurs in the blood. The mineralization of bone is not explainable on the basis of a mere pptn. of bone salts from body fluid." F. L. SEYMOUR-JONES

Studies on the physiology of the pyrimidines. III. The intermediary metabolism of uracil. LEOPOLD R. CERECEDO. *J. Biol. Chem.* **88**, 695–700(1930); cf. *C. A.* **24**, 4083.—About half the N of isobarbituric and isodialuric acids, when fed in small quantities to dogs, is metabolized to urea. At the same time the ethereal S in the urine increases at the expense of the inorg. S. Conclusion: Part of the above acids are excreted directly as sulfates. K. V. THIMANN

Diffusible non-protein constituents of blood and their distribution between plasma and corpuscles. OTTO FOLIN AND ANDREA SVEDBERG. *J. Biol. Chem.* **88**, 715–28 (1930).—The av. proportion of sugar in the corpuscles to that in the plasma is about 60%, and in diabetes 70%. For urea, creatinine, uric acid and amino N the proportions are 80, 75, 22 and about 30%, resp., in normal persons. To correspond with equal concn. in the water of the cells and plasma (cf. Ege and Roche, *C. A.* **24**, 2482) the proportion of each solute should be 80%. Analyses of the non-protein N of unlaked blood are given, and it is held that this should be more useful than laked blood in the future for clinical analyses. K. V. THIMANN

G - PATHOLOGY

H. GIDEON WELLS

Liver autolysis in vivo. EDMUND ANDREWS AND LEO S. HRDINA. *Proc. Soc. Exptl Biol. Med.* **27**, 987–8(1930).—Autolyzed ground liver was sterilized and introduced into the peritoneal cavity of the dog. An overwhelming *Bacillus welchii* peritonitis resulted. In some way, the ordinary flora of the intestine, as represented by the Welch bacillus, were allowed to pass through the intestinal wall and infect these masses of sterile liver. Concd. aq. exts. of fresh and of autolyzed liver caused similar peritonitis. Liver repeatedly extd. with boiling H_2O, boiling $CHCl_3$, alc. and ether mixts and even purified liver proteins induced this peritonitis. Exts. of autolyzed liver, dialyzed in collodion bags, did not cause fatal peritonitis when injected intraperitoneally. C. V. BAILEY

Effect of drying in air on the goiter-producing substance in cabbage. DAVID MARINE, EMIL J. BAUMANN, BRUCE WEBSTER AND ANNA CIPRA. *Proc. Soc. Exptl. Biol Med.* **27**, 1025–6(1930).—Cabbage was steamed for 0.5 hr. and the juice expressed under 450-lb. pressure. The resultant cake was dried in an atm. drum drier or by exposure to a current of air at room temp. for about 36 hrs. The prepns. were moistened and fed to rabbits in proportion to body wt. for about 20 days. Controls were fed with steamed-pressed cabbage which had not been dried. The test rabbits remained normal, the controls developed thyroid hyperplasia. C. V. BAILEY

Serological studies in experimental poliomyelitis. CLAUS W. JUNGEBLUT. *Proc. Soc. Exptl Biol. Med.* **28**, 7–9(1930).—To each of 3 test tubes contg. 1.5 cc. of a 5% saline ext. of monkey brain and cord tissue, were added, resp., 0.2 cc., 0.15 cc. and 0.1 cc. of the test serum. The vols. were made up to 2 cc. with 0.4% NaCl soln. and after standing for 1 hr., 0.075 cc. of 1% gold chloride soln. was added to each tube. Observations were made at the end of 1 hr. and after standing overnight. With 23 normal monkey sera, pptn. in the first 2 tubes was complete in 78.2% and partial in 21.8%. With 66 sera from poliomyelitic monkeys pptn. in the first 2 tubes was absent in 81.8% and partial in 18.2%. The nature of the phenomenon has not been detd. C. V. B.

Toxin-antitoxin reactions on the surface of collodion particles. JULES FREUND. *Proc. Soc. Exptl. Biol. Med.* **28**, 65–70(1930).—Collodion particles treated with diphtheria toxin were flocculated by diphtheria antitoxic horse serum. This flocculation was reduced considerably when toxin heated for 2 hrs. at 55° was used. Collodion particles treated with formalin toxoid were also flocculated by antitoxin and previous heating of the toxoid did not affect the flocculation phenomenon. Toxin-treated parti-

cles injected into the skin of guinea pigs produced redness, edema and necrosis; inflammation was prevented when antitoxin was injected simultaneously. Collodion particles treated with *tetanus* toxin were not flocculated by antitoxin; animal experimentation showed that the toxin was adsorbed by the particles and was neutralized by high dilns. of antitoxin. C. V. BAILEY

Study in post-operative blood chemistry. EDMUND ANDREWS AND KNUTE REUTERSKIOLD. *Ann. Surgery 92, 786–99(1930).*—*Blood chem. studies were made in patients 24 to 36 hrs. after operation. No significant changes were found in the leucocytes, blood pressure, temp., pulse, blood sugar, H_2O content of the blood, chloride or CO_2. Marked changes were found in the Aldrich-McClure test indicative of tissue thirst The permeability of the skin was increased. Profound changes in the mineral salt* balance were noted. The K:Ca ratio often fell below 1. RACHEL BROWN

Pleural effusions. MAX PINNER AND GEORGINE MOERKE. *Am. Rev. Tuberc.* 22, 121–83(1930).—Expts. on rabbits show that the normal pleura is highly permeable in either direction for the constituents of the blood. In patients under pneumothorax treatment for pulmonary tuberculosis and with pleural effusions, a marked decrease of the pleural permeability is shown by actual expts. and must be assumed to exist from the results of chem. studies of the blood and the pleural effusion. Neither chem. nor cytological, nor serological data afford *per se* dependable diagnostic or prognostic criteria The failure of resorption of pleural effusion cannot be explained by their chem. constitution; it must be due to an alteration in pleural permeability. H. J. CORPER

Serum-calcium in pneumonoconiosis. MARTIN J. SOKOLOFF AND A. CANTAROW. *Am. Rev. Tuber.* 22, 449–54(1930).—In a group of 31 patients with pneumonoconiosis, 15 of whom had an assocd. active tuberculous lesion, the serum Ca ranged from 7.98 to 14.81 mg. per 100 cc., being above normal in 26 patients, subnormal in 1 and normal in 3. The serum-Ca level bore no relation to the incidence or activity of the complicating tuberculous process. The hypercalcemia in pneumonoconiosis is in all likelihood dependent upon the increase in the CO_2 tension of the blood, which is an inevitable consequence to the pulmonary lesion. H. J. CORPER

Further studies on the nature of the processes underlying the Abderhalden reaction. EMIL ABDERHALDEN AND SEVERIAN BUADZE. *Fermentforschung* 12, 129–79(1930), cf. *C. A.* 24, 1131.—The highly specific character of the Abderhalden reaction is further illustrated by expts. in which testicular and ovarian material was injected into castrated male and female dogs. Irrespective of the sex of the animal and the source of the glandular material, the urine excreted during the first 24 hrs. contained enzymes that were specific toward the particular substrate that had been used in the treatment. The serum of the same animals gave a neg. reaction when the usual technic was employed but the reaction became pos. when a more concd. enzyme prepn., obtained by drying the serum and extg. with 0.9% NaCl, was used. The sp. enzyme does not originate in the corresponding organ, since it can thus be developed after removal of the organ There is undoubtedly an intimate relationship between the occurrence of enzyme action after parenteral administration of substances alien to blood and the numerous immunity reactions. Peptones prepd. from testicular or placenta proteins produce the same specific response, *i. e.*, the urine gives a pos. Abderhalden reaction with the corresponding substrate, provided the peptone is of high mol. wt. such as that obtained by brief hydrolysis of the protein with an equal vol. of 70% H_2SO_4 at 37°. If, however, the hydrolysis is carried further by more concd. acid and longer digestion, the peptone loses its specificity and fails to produce a specific enzyme. Similar observations were made with peptones prepd. from carcinoma proteins. An apparent exception to the specific response is the frequent occurrence of a non-specific protease which attacks certain proteins like casein, fibrin, edestin and pumpkin seed protein, which are readily amenable to enzymic proteolysis. The serum of an animal sensitized to a particular substrate, or the enzyme-contg. ppt. from the urine, when injected into a 2nd animal results in the excretion of urine with the same specificity and sometimes greater activity. Similarly, gravid human serum injected into a dog gives rise to urine with a specific reaction toward placenta substrate. In all expts. of this nature it is important to withdraw the serum sample while the animal is fasting, and to use only the morning urine. It is important also to maintain the animals in a healthy condition, with uniform diet and carefully regulated water consumption, otherwise complications may arise in the development of specific defensive enzymes. A. W. DOX

Chemical investigation of the precipitate from hemoglobin and anti-hemoglobin-serum and remarks on the nature of the antibodies. FRIEDRICH BREINL AND FELIX HAUROWITZ. *Z. physiol. Chem.* 192, 45–57(1930).—The ppt. from hemoglobin and anti-hemoglobin serum contains 2–8% lipoids, 5–10% salts and an org. residue which

gives a typical protein analysis of C 50.7, H 7.4 and N 17.7%. The bulk of the ppt. consists of a protein which resembles the globulin of the immune serum; on hydrolysis it yields the same quantities of tyrosine, cystine and arginine. The antigen content of the ppt. depends on the conditions of pptn. With low hemoglobin concns. (1:1000–1:200,000) the ppt. consists of 6–11% hemoglobin; with higher concns. the hemoglobin content rises to 24% of the lipoid-free ppt. The lipoids of the ppt. resemble those lipoids which are pptd. with the globulins on half satn. of the serum with $(NH_4)_2SO_4$. They contain neither cholesterol nor phosphatides nor cerebrosides in demonstrable quantities. On hydrolysis they yield fatty acids. The variable quantity of these lipoids suggests that they represent merely concomitant substances which are of no particular significance for the pptn. In the formation of antibodies it is probable that the antigens exert a disturbing influence in an earlier stage of the process of globulin formation, so that the non-specific components (amino acids and peptides) are built up into a specific globulin mol. Antibodies are thus globulins which, under the disturbing influence of antigens, have been formed in place of the normal globulins. The antibody is held in soln. by salts, and like the globulins it is pptd. when the salts are removed by dialysis. The precipitin reaction should therefore not be regarded as a pptn. reaction between 2 sol. substances. It is a reaction between antigen and the sol. salt compd. of the insol. antibody. Possibly the antigen displaces the salts from the surface of the antibody and this may be one of the causes of pptn. The precipitin reaction can be further complicated by the protective colloid effect of the albumins, and by the presence of several active groups in the antigen or antibody mol., thus binding several mols. of whichever reacting substance is present in excess. A. W. Dox

Urochrome and urochromogen in healthy and urotuberculous urine. Masanoshin Saheki. *Tohoku J. Exptl. Med.* **14**, No. 1, 36–43(1930).—Weiss (*C. A.* **17**, 1033, 1666) devised a method for the detn. of urochromogen in the urine and suggested that since it is increased in tuberculosis its detn. might be used as a method of diagnosis. Saheki examd. the urine of 16 healthy males, ages 11 to 64 yrs., using Weiss' method. The urochromogen was found to vary between such extremely wide limits as to have no practical diagnostic value. L. E. Gilson

The hematopoietic substance of anemic serum. A. Zih. *Arch. ges. Physiol.* (*Pflügers*) **225**, 613–9(1930).—The serum of animals rendered anemic by bleeding contains no bilirubin. After 24 to 36 hrs., hemoglobin can be demonstrated in the sera of about half of the anemic animals. The hematopoietic activity of such sera is due to the presence of this hemoglobin. Normal sera, in which hemolysis has occurred, also show this hematopoietic activity. Arthur Grollman

The passage of dye mixtures through normal and poisoned kidneys. P. Steffanutti. *Arch. ges. Physiol.* (*Pflügers*) **226**, 148–63(1930).—The rate at which dyes are excreted by the glomerulus and tubule differs. Hence injection of mixts. of dyes results in their partial sepn. by the kidney. Comparison of the manner in which such dyes are excreted by pathol. kidneys with the normal permits the detn. of the site of injury in the kidney. Arthur Grollman

Effect of cryptorchidism and of castration on the chemical composition of rats. Vladimir Korenchevsky and Marjorie Dennison. *Biochem. J.* **24**, 954–60(1930).—The amt. of intra-abdominal fat was increased and the N content decreased in both cryptorchid and castrated animals. Benjamin Harrow

Disturbance of metabolism produced by bony and non-bony injury, with notes on certain abnormal conditions of bone. David P. Cuthbertson. *Biochem. J.* **24**, 1244–63(1930).—In normal healing fracture cases the metabolism of Ca showed but little change. There was, however, a marked loss of N, P and S. The S:N and P_2O_5:N ratios suggested that the material catabolized was probably muscle. B. H.

Standardization of cholesterolized alcoholic beef heart antigen for use in complement-fixation procedures employing warm preliminary incubation. B. S. Levine. *Am. J. Syphilis* **14**, 500–5(1930).—Only fresh beef heart freshly ground and rapidly dried should be used in the prepn. of antigen exts. The cholesterol *content of the antigenic dose* should always be the same for any particular complement-fixation procedure. The antigenic titer for any particular complement-fixation method should be of a fixed value. An antigen used in any particular complement-fixation modification is to be regarded with reasonable assurance as of the same standard as the one in prior use only after it has yielded a reasonable no. (50 or 100) of pos. and neg. concordant results. B. S. Levine

The thyro-parathyroid graft and calcemia. J. F. Lewis and Rebecca Gerschmann. *Ann. farm. bioquim.* **1**, 89–98(1930).—The lobes of the thyroid with the corresponding parathyroid were removed under anesthesia in 5 to 10 min. As soon as the

effects of tetani due to hypocalcemia became manifest a lobule of the thyroid with parathyroid was grafted on to the circulatory system. The blood Ca then became increased, the blood P decreased and the tetany disappeared. By removal of the graft the condition can again be reversed. The assocn. of the parathyroid is essential to the production of the described effects. B. S. LEVINE

The influence of hyperglucemia on the amylolytic power of the saliva and blood. TULLIO GAYDA. *Arch. sci. biol.* (Italy) **15**, 147–59(1930).—The aim of the investigation was to study the behavior of the amylolytic power of the saliva and blood serum when the animal is under conditions opposite to those produced by insulin. The hyperglucemia produced in the rabbit by a subcutaneous injection of glucose or adrenaline, or by a puncture of the floor of the 4th ventricle, is accompanied by an increase of the amylolytic power of the saliva. When the hyperglucemia disappears, the amylolytic power returns to normal. Under the same conditions the amylolytic power of blood serum does not undergo any changes, except perhaps a slight diminution after the injection of adrenaline. The increase in the amylolytic power of the saliva, which follows hyperglucemia, is in all probability due to the hyperinsulinemia caused by the hyperglucemia. PETER MASUCCI

Sweat and nutrition. MAURICE BOIGEY. *Presse méd.* **38**, 357–8(1930).—M. deals with the compn. of sweat in normal and pathol. conditions and the methods of producing sweat in therapeutics. A. F. MEYER

Observations on human tetany. I. Spontaneous tetany in adults. HARALD A. SALVERSEN. *Acta Med. Scand.* **73**, 511–25(1930).—In one case of idiopathic tetany a low blood Ca was observed. The case was under observation for 3 years. Tetany occurred only during the winter months, and there was a spontaneous rise in blood Ca in the spring. Ultra-violet radiation produced normal blood Ca and general improvement. The case was regarded as a chronic hypoparathyroidism. In another case the low blood Ca was the cause of tetany and diarrhea and was due to a temporary parathyroid insufficiency which finally disappeared under Ca treatment. In a third case, in a patient with pancreatic diarrhea adiposa, the tetany was not of hypocalcemic origin but was probably due to low Cl. S. MORGULIS

The mitogenetic radiation of blood and urine of healthy and sick persons. WERNER W. SIEBERT. *Biochem. Z.* **226**, 253–6(1930).—It is claimed that the urine like the blood of healthy persons emits mitogenetic radiation which is absent in blood and urine from sick individuals. S. MORGULIS

The Gurwitsch radiation of human blood and its bearing upon the diagnosis of carcinoma. HEINRICH GESENIUS. *Biochem. Z.* **226**, 257–72(1930).—Expts. corroborate the findings of Gurwitsch-Salkind of the different types of radiation produced by normal and by pathol. blood. With the yeast as an indicator, it was found that carcinoma blood manifests a very weak radiation effect or none at all. This is also true of the blood of severe anemias. The loss of radiation of the blood has been found in carcinoma patients even before cancer could be detected by any other means. S. MORGULIS

Cholesterol and lipoid phosphorus in experimental hydrophobia. D. ZUVERKALOV AND I. GOLDENBERG. *Biochem. Z.* **226**, 278–85(1930).—The infection of the central nervous system accompanying hydrophobia produces in the first days hypercholesteremia, which may be due to the disturbance in the water content resulting from starvation. But the rise in the blood lipoid P is the most characteristic change which occurs from the moment of infection and persists until the animal dies. S. M.

A chemical method for measuring carcinolysis. R. WILLHEIM AND KURT STERN *Biochem. Z.* **226**, 315–24(1930).—Freund and Kaminer have shown that blood serum from normal persons unlike that of carcinoma patients can dissolve tumor cells. This reaction, which carried out microscopically involves many errors, is now proposed to be carried out chemically because in the cytolysis fat-like substances are set free giving characteristic color reactions with neutral red. Fat detns. by Bang's method give generally similar results. S. MORGULIS

Comparative studies on the action of ultra-violet light on complement, amboceptor, agglutinin, the Wassermann reaction and the precipitating property of serum in vitro. ALEXANDER HASSKÓ. *Biochem. Z.* **226**, 462–81(1930).—Complement, the antibodies in Wassermann pos. sera, amboceptor, agglutinin and precipitin all equally lose their specific activity partly or completely under the influence of ultra-violet radiation, this depends upon the diln. of the protein, its colloidal properties and various other conditions. The pptn. of egg albumin through antihorse-serum is prevented sooner than the pptn. by neoarsphenamne and egg albumin radiated for 9 hrs. is non-precipitable by neoarsphenamine. S. MORGULIS

Biochemical studies on endemic goiter in Hungary on the basis of the iodine deficiency theory. J. Bodnar and Johann Straub. *Biochem. Z.* **227**, 237–44(1930).—In the Bodahegyközség district 82% of the school children and 24.6% of the entire population suffer from endemic goiter. The drinking water of the district contains 0 to 1γ I_2 per l. and the amt. of I_2 consumed with the food in one child was 15.8γ per day. The daily urine of sick children contained 8γ I_2 whereas that of normal children and adults contained 35γ I_2. S. Morgulis

The determination of the urinary sugar content in diabetes in relation to the 24 hour quantity and to the specific gravity of the urine. Michael Breitmann. *Endokrinologie* **7**, 369 71(1930).—A correlation between the amt. of sugar in the urine and its vol. and sp. gr. can be worked out from the formula: $x = 0.4 + 0.4\sqrt{y-20}$, where x = % of sugar, y = the product of l. of urine by the last 2 digits of the sp. gr. value. It is also possible to det. the urine quantity from the % of sugar and sp. gr., or the sp gr. from the % of sugar and the 24-hr. urine vol. by means of the formula: $y = 6.25x^2 - 5x + 21$. S. Morgulis

Protective action of cholesterol against the shocks produced by flocculating. Auguste Lumière and Mme. R. H. Grange. *Compt. rend.* **191**, 423–5(1930).—It has been shown that shocks provoked by intravascular injection of such compds. as hexylresorcinol and certain sulfonic derivs. of naphthalene could be suppressed by previous injection of an oily soln. of cholesterol. It was thought that anaphylactic shock of the type due to flocculation by baryta or India ink could also be suppressed by cholesterol. The solns. were prepd. by 2 methods: (*a*) The serum of a male rabbit is used after successive injections of oily soln. of cholesterol during a month. The serum contains about 1.9 parts cholesterol per 1000. (*b*) The serum of a normal rabbit is satd. with cholesterol; about 1.5 parts per 1000 is absorbed. It was shown that when doses of India ink or baryta were mixed with 0.6 cc. of this cholesterol serum, the shock normally produced by these flocculates is markedly decreased. N. M. N.

The isoelectric state of tuberculins. M. A. Linnikova. *Arkh. Biol. Nauk* **30**, 187–90(1930).—The isoelec. pts. of tuberculins produced from human and bovine types were studied by means of detg. max. pptn. at varying p_H values. For tuberculins used in medical practice the isoelec. pt. varied from 3.83 to 5.1, while those in veterinary use gave values of 3.9–4.4. W. A. Perlzweig

Content of proteins, electrolytic dissociation and surface tension of blood serum in tuberculous children during the tuberculin shock. Ignazio Gatto. *Pediatria Rivista* **38**, 1112–21(1930), cf. *C. A.* **24**, 5064. Ten allergic infants with active tuberculous foci were injected with tuberculin. Blood samples taken before injection and at the height of the febrile reaction were examd. for protein content, electrolytic dissocn. and surface tension. At the height of the fever the protein content was diminished in most cases, while electrolytic dissocn. and surface tension did not undergo const. changes. G. Schwoch

The behavior of fibrin in the anemias. E. M. Mondini. *Pediatria Rivista* **38**, 1062–74(1930).—The detn. of the fibrin content of plasma from 10 normal children gave values between 0.331 and 0.412% with an av. of 0.368%. The fibrin was diminished in pseudoleucemic splenic anemia, in anemia of the hypoplastic type, and in the anemia caused by the Leishman parasite. In general the reduction in fibrin content was proportional to the degree of anemia. The fibrin was increased in secondary anemia assocd. with metapneumonic empyema, and in a child with tuberculosis in the 2nd stage. Normal fibrin values were found in Werlhof's disease and in posthemorrhagic anemia. The findings suggest a possible relation between bone marrow and fibrinogen formation. G. Schwoch

Experimental hyperparathyroidism in guinea pigs leading to ostitis fibrosa. Aaron Bodansky, John E. Blair and Henry L. Jaffe. *J. Biol. Chem.* **88**, 629–47(1930).—The effect of parathyroid hormone on the serum Ca and P of guinea pigs is much more marked after 60 hrs. fast than in fed animals, because of the basic character of the diet, and to this effect the neg. results of McLeod and Taylor (*C. A.* **19**, 3524) and others are due. Injection of 10–20 units per 100 g. body wt. raised the serum Ca, considerably in young animals, and slightly in adults, above the normal value of 10.5 mg. per 100 cc. In all cases the max. effect was observed 24 hrs. after injection. In fasting animals the serum P was markedly raised—more in young than in adults; in fed animals the serum P was almost unchanged. Bone lesions after injection were observed in the young but not in the adult. After continued small injections, doses of 100 units could be given without extreme hyperphosphatemia, and in these cases bone resorption of Na typical ostitis fibrosa lesions were produced. K. [illegible] of body wt. [illegible] imals were given

Lipemia in hemorrhagic anemia in rabbits. A. Hecht-Johansen

88, 669–73(1930); cf. Ellerman and Meulengracht, *Ugesk. Laeger* 79, 1287(1917). The % hemoglobin, lipoid content, serum protein and colloid osmotic pressure (cf. Krogh and Nakazawa, *C. A.* 22, 600) of the blood of rabbits in hemorrhagic anemia were detd. Onset of lipemia was coincident with the lowest osmotic pressure, which remained const. at about 270 mm. water. The protein content was unchanged throughout. K. V. THIMANN

The distribution of acid-soluble phosphorus compounds in tumor tissue. K. W. BUCHWALD. *J. Cancer Research* 14, 536–44(1930).—A fractionation of the acid-sol. phosphates of 3 types of tumors was carried out. The orthophosphate and Ca contents of the tumors were low when necrotic material was excluded from the analysis. When the necrotic areas could not be removed completely inorg. phosphates and Ca were often very high. Phosphocreatine could not be detected in tumor tissue. "Pyrophosphate," sol. and insol. Ba esters showed a similar distribution in tumor tissue as in normal tissue. The total lipide and lecithin-cephalin P content of tumor tissue was not particularly high when compared with that of liver and kidney. H. G. W.

Changes in the blood chemistry in malignant disease with special reference to carbohydrate tolerance and alkalosis. PAULINE BEREGOFF. *J. Cancer Research* 14, 559–67(1930).—A series of 300 patients was studied in whom the blood showed a tendency toward alkalosis, low carbohydrate tolerance, deficiency in Ca and a low CO_2 content. All bloods of cancer patients examd. in these expts. exhibited a pos. carbohydrate curve and a tendency to alkalosis. However, pos. carbohydrate curves were obtained in other pathol. states such as hyperthyroidism, acromegaly and diabetes but in these conditions no alkalosis was demonstrable. As an indication of the presence of malignant disease a pos. carbohydrate curve is significant only in the presence of alkalosis. Examn. of the blood of 25 individuals not suffering from cancer yielded a neg. carbohydrate curve in every instance and the p_H of the bloods was within normal limits. The concn. of the ionized Ca averaged 22.6 mg. per l. It would appear from these expts. that the carbohydrate tolerance test and the H-ion concn. are of greater value in eliminating the presence of malignant disease than of proving its existence. H. G. WELLS

Observations on the courses of different types of Bright's disease, and on the resultant changes in renal anatomy. D. D. VAN SLYKE, EDGAR STILLMAN, EGGERT MÖLLER, W. EHRLICH, J. F. MCINTOSH, L. LEITER, E. M. MACKAY, R. R. HANNON, N. S. MOORE AND CHRISTOPHER JOHNSTON. *Medicine* 9, 257–386(1930).—An exhaustive study correlating the results of chem. study, particularly of the blood, with the anatomical and clinical features of nephritis; several years of study in the hospital of the Rockefeller Inst. are summarized. Their observations support the view of Volhard and Fahr and of Addis that the 3 types of Bright's disease are essentially different in their genesis and pathol. nature: the hemorrhagic or glomerular, marked primarily by glomerular inflammation, with hematuria and usually diminished renal function (even in the acute stage); the sclerotic disease, marked primarily by pathol. changes in the small arteries of the kidneys (and usually other organs), with hypertension as the first sign and diminished renal function only as a terminal phenomenon; the degenerative disease or diseases, called nephrosis, marked primarily by degenerative changes in the kidneys, without hypertension and with hematuria. The diagnoses have been made chiefly on the basis of observations of the urea-excreting power of the kidneys, measured by the blood urea clearance (cc. of blood cleared of urea by 1 minute's excretion), of the hematuria, blood pressure, plasma protein content, proteinuria and edema. In acute hemorrhagic nephritis the prognosis was found to be independent of the severity of the disturbances during the first weeks, with the single exception of the plasma albumin content. The majority of cases in which this fell to a low level became chronic. Intensity of hematuria, proteinuria and degree of hypertension had no apparent relation to the probability of recovery. Fall of the renal function to as low as 10% of normal, measured by the blood urea clearance, was found not inconsistent with apparently complete recovery. The majority of cases showed during the first 2 months a decided fall in renal function measured by the blood urea clearance. In all these cases which recovered or improved, however, the blood urea clearance began to rise within 4 months after the acute hemorrhagic onset. The occurrence or non-occurrence of this rise in renal function constituted the most definite single prognostic sign. The tendency to non-cardiac edema was found to parallel approx. the fall in albumin content of the blood plasma, except during the first weeks of acute hemorrhagic nephritis. Edema during this period was repeatedly observed even when the plasma protein remained normal. The edema was, however, moderate and temporary unless by neoarsphenamin deficit developed. In all stages of nephrosis plasma deficit and

tendency to edema occurred together. In arteriosclerotic renal disease plasma proteins were never markedly reduced, and only cardiac edema was observed. Of the different features of the disease that were followed, the blood urea clearance proved to be the most closely related to the onset of final renal failure. The renal function, measured by the clearance, could apparently remain indefinitely at 10% of normal without uremia; but when it fell to below 5% uremia occurred and was usually fatal.
H. G. WELLS

The action of various lipoids on the growth of mouse cancer. P. RONDONI. *Z. Krebsforsch.* **32**, 417–24(1930).—Injection of cholesterol increases, and of lecithin decreases growth, especially pure lecithin. Some unknown acetone-sol. exts. of organs are also more or less inhibitory. Removal of cholesterol from tissue exts. by pptg. with digitonin does not increase the inhibitory effect, but injection of digitonin into mice depresses tumor growth. H. G. WELLS

Experimental tar cancer. C. C. TWORT AND J. M. TWORT. *Z. Krebsforsch.* **32**, 491–519(1930).—A summarization of results in over 45,000 expts., which presents much information concerning the conditions under which tar produces cancer, but no consideration of the chem. nature of the agent inciting cancer. H. G. WELLS

Biochemistry of the Rous sarcoma in fowls. I. Biophysics. 4. Hydrogen-ion concentration. FRANT. KOBLIHA. *Z. Krebsforsch.* **32**, 544–65(1930).—By means of quinone electrodes, controlled by H electrodes, K. detd. the p_H in blood in serum, and in exts. of tumors and normal tissues. No characteristic alterations were found in the blood, but the serum after the 15th day was more alk. because of influx from the tumor tissue. The organ exts. also showed no characteristic changes. Muscle tissue at the site of injection of either tumor tissue or normal tissue becomes acid because of the inflammatory reaction; but after 6 days growing tumors produce an alk. reaction. The muscle tissue about the growing tumor has a strongly acid reaction while the tumor grows more alk. with age. Measurement of p_H has no clinical diagnostic value.

H—PHARMACOLOGY

A. N. RICHARDS

Comparison of effects of various preparations of anterior pituitary gland on thyroid of guinea pig. LEO LOEB AND R. B. BASSETT. *Proc. Soc. Exptl. Biol. Med.* **27**, 490–2 (1930).—Anterior pituitary glands of cattle were dried and powdered; 5 g. of the powder was extd. with 100 cc. of 0.5% AcOH or with 100 cc. of 0.1% NaOH soln. for 24 hrs. in the ice chest; the fluid was filtered, brought to p_H 7.8, refiltered and passed through a Seitz bacterial filter. Sets of guinea pigs were given daily intraperitoneal injections of 1 cc. of either the acid or the alk. exts. over a period of 7 days. On each day the thyroid gland from 1 pig of each set was removed and examd.; hypertrophy followed with surprising rapidity; the max. increase in mitotic activity occurred on the 3rd day and the max. hypertrophy of the acinus cells and absorption of colloid was reached on the 6th day. Acid and alk. exts. acted in a similar manner and larger doses had no added effect. The thyroid of the rat responded but slightly to the above injections. C. V. B.

Oral administration of anterior pituitary tablets and our laboratory preparations on compensatory hypertrophy of thyroid gland. LEO LOEB AND WALTER J. SIEBERT *Proc. Soc. Exptl. Biol. Med.* **27**, 495–7(1930).—Subtotal thyroidectomy was performed on 54 guinea pigs; one group was fed Armour & Co.'s anterior pituitary substance; another group was fed an equal amt. of dried fresh anterior pituitary glands obtained from the slaughter house. After 20 or 30 daily feedings the remaining parts of the thyroid glands were examd. Armour's tablets largely prevented compensatory hypertrophy; the dried fresh glands did not have this effect. C. V. BAILEY

The influence of constant intravenous injection of adrenaline on blood sugar of rats. C. F. CORI AND G. T. CORI. *Proc. Soc. Exptl. Biol. Med.* **27**, 560–1(1930).—In the amytalized rat 0.0002 mg. of adrenaline per min. is the smallest rate of intravenous injection which produces a definite rise in blood sugar; and 0.001 mg. per kg. per min. is the minimal rate to produce changes in blood pressure. The carbohydrate metabolism and the vascular system are less sensitive to adrenaline in the rat than in the rabbit, and decidedly less sensitive than in man. C. V. BAILEY

The effect of experimental hyperphosphatemia on calcium and phosphorus excretion. J. D. BOYD, H. M. HINES AND GENEVIEVE STEARNS. *Proc. Soc. Exptl. Biol. Med.* **27**, 766–8(1930).—Dogs were given intravenous injections of 50% soln. of Na glycerophosphate in amts. equiv. to 0.1 g., 0.25 g., 0.5 g. and 1.0 g. per kg. of body wt. The prepn. contained 11% of P and no inorg. phosphate. Control animals were given

Na phosphate in amt. equiv. to 0.5 g. of Na glycerophosphate per kg. Regardless of the size of the dose, 40–60% of the injected P was excreted in the urine within 1 hr.; $^2/_3$ of this was excreted in the first half hr. Even with the smaller doses part of this was excreted as an org. compd.; the amt. so eliminated increased with the dosage. Ca excretion was increased roughly proportionally to the amt. of P administered. With the larger doses *serum* Ca was definitely decreased. Moderate or severe tetany followed the inorg. P injection in the controls; twice this amt. of Na glycerophosphate was required to produce similar symptoms. The alkali reserve and serum chloride values remained normal. C. V. Bailey

Effect of posterior pituitary lobe extracts on the intestine of man and animals. H. A. Carlson. *Proc. Soc. Exptl. Biol. Med.* **27**, 777–9(1930).—Com exts. of posterior pituitary gland have a definite stimulating effect upon the human colon and small intestine, especially when given intravenously. In the dog these effects are inconstant; stimulation is rather exceptional. The intestine of the rabbit is more responsive to pituitary ext. than that of either the dog or the cat. C. V. Bailey

Effect of continued administration of iodine on the growth of the albino rat. Lafayette B. Mendel and Hubert Bradford Vickery. *Proc. Soc. Exptl. Biol. Med.* **27**, 806–9(1930).—Nine male albino rats were fed a diet consisting of casein 35%, cornstarch 37%, lard 15%, butter fat 9%, Osborne-Mendel salt mixt. 4% (*C. A.* **12**, 1310) plus 10 drops of cod-liver oil and 0.2–0.3 g. of dried yeast daily. Twelve test rats were given in addn. 1.107 mg. of KI daily for periods of 200–400 days. The av. rates of wt. increase were approx. equal for test and control animals and histologically the thyroid glands were of similar structure. Prolonged administration of I in doses of approx. 3.3 mg. daily per kg. is apparently harmless C. V. Bailey

Effect of sodium salicylate on intradermal reactions of rabbits. O. E. Hagebush and R. A. Kinsella. *Proc. Soc. Exptl. Biol. Med.* **27**, 922–4(1930).—Daily intravenous injections of 0.2 g. per kg. of Na salicylate in 5% aq. soln. suppressed the allergic dermal reactions of rabbits to filtrates of hemolytic streptococcus. C. V. Bailey

The effect of ether and chloroform on kidney function in dogs with obstructive jaundice. B. Dalton, L. Sperling, H. Dvorak and O. H. Wangensteen. *Proc. Soc. Exptl. Biol. Med.* **27**, 961–2(1930).—Terminal anuria occasionally accompanies protracted obstruction of the common bile duct. No evidence was obtained to indicate that the administration of ether or $CHCl_3$ impaired the kidney function in an animal with complete obstructive jaundice. C. V. Bailey

The excretion of xylose by glomerular and aglomerular kidneys. Norman Jolliffe. *Proc. Soc. Exptl. Biol. Med.* **28**, 5–6(1930).—In fish with aglomerular kidneys only the faintest traces of xylose appear in the urine following intramuscular or intravenous injection of xylose. In fish with glomerular kidneys injected xylose is readily recovered in the urine. C. V. Bailey

Differentiation of the in vivo and in vitro actions of tissue extracts. C. A. Mills. *Proc. Soc. Exptl. Biol. Med.* **28**, 18–21(1930).—The tissue fibrinogen consisted of the purified globulin fraction of fresh calf lung exts. Certain batches after weeks of storage lost their clot-promoting activity entirely on intraperitoneal injection into the rabbit, although they retained their full activity *in vitro;* ultra-violet light irradiation of the fresh tissue fibrinogen had a similar effect. Treatment with Lloyd's reagent removed the factor effective in *in vitro* expts. without decreasing the *in vivo* potency. The tissue fibrinogen, boiled vigorously for a few min. and filtered, retained its *in vitro* clotting effect but gave a marked inhibition of clotting when injected intraperitoneally. Evidently the fibrinogen contained 2 distinct clot-promoting substances. C. V. B.

Specific soluble substances of the pneumococcus in the blood in penumonia. Harold L. Amoss. *Proc. Soc. Exptl. Biol Med.* **28**, 23–5(1930).—The specific sol substances of 3 types of pneumococcus were found in the concd. filtrate or ultrafiltrate of the patients blood serum, in 1 case as early as 13 hrs. after the intial chill. In 6 out of 7 cases the blood culture was neg. The test requires less time than the sputum culture or the mouse method; it has no advantage over the sputum ext. method. The details of 2 methods are given. C. V. Bailey

Effect of tar on experimental teratoids in the rat. F. A. McJunkin. *Proc. Soc. Exptl. Biol. Med.* **28**, 25–6(1930).—A 1–1000 stock diln. of a thick ether ext. of coal tar was made in 5% gelatin, and higher dilns. were made with 1% gelatin. About $^1/_2$ an embryo was drawn directly into a syringe, mixed with an equal vol. of tar soln. and injected into the subcutaneous groin tissue of $^3/_4$ grown rats. After periods of 20 to 150 days the rats injected with 1–500,000 diln. of tar showed distinct teratoid growth, teratoids occasionally followed the 1–200,000 diln., and were absent when dilns. of 1–25,000 were used. No malignant transformations were found. C. V. Bailey

Pyloric occlusion from sulfuric acid. HERBERT A. BRUCE. *Ann. Surgery* **92**, 897-9(1930).—Report of a case in which the pathol. condition caused by H_2SO_4 taken by mouth was confined to the stomach and relieved by operation. R. B.

Alkalosis due to pyloric stenosis simulating nephritic uremia. DAMON B. PFEIFFER. *Ann. Surgery* **92**, 900-9(1930).—The treatment of alkalosis consists in restoring the chem. balance of the blood plasma. The diminished chlorides should be restored by the administration of salt soln. and glucose should be given to protect against protein destruction. RACHEL BROWN

The effect of parathyroid extract injected into cerebrospinal fluid. I. I. NITZESCU. *Compt. rend. soc. biol.* **102**, 1123-5(1929). Injection of 1.0-2.5 cc. (20-50 units) of parathyroid ext. into the cerebrospinal fluid of dogs was followed in 7 cases by an increase in blood Ca of 1.8-3.0 mg per 100 cc.; in 2 cases, the increases were 0.9 and 1.0 mg., and in another case, no change resulted. Injection of saline soln. produced no effect. The hemoencephalic barrier is permeable to the parathyroid hormone (which is not the case with insulin). B. C. BRUNSTETTER

The impermeability of the placenta to the substance in the anterior lobe of the hypophysis active on the thyroid gland. MAX ARON. *Compt. rend. soc. biol.* **103**, 151-2 (1930).—An aq. ext. of the anterior lobe of the hypophysis when injected into the guinea pig causes the excretion of colloid in its thyroid gland, the newly born guinea pig being particularly sensitive. Large doses of the aq. ext. were injected into pregnant guinea pigs at various stages of gestation; the thyroid gland of the mother always showed a marked change, but no reaction was produced in the thyroid of the fetus. Therefore the placenta is impermeable to the active principle. B. C. BRUNSTETTER

The early variations of hepatic and of muscular glycogen in the normal dog under the influence of insulin. F. RATHERY, R. KOURILSKY AND MLLE. S. GIBERT. *Compt. rend. soc. biol.* **103**, 307-8(1930). The injection of insulin (20-90 units) into dogs causes a marked drop of hepatic glycogen. A decrease of 46% was evident 15 min. after injection. The decreases in liver glycogen in 13 dogs ranged from 30 to 85%; the min. was obtained by an injection of 60 units in the portal vein and the max. when 60 units were given by ordinary intravenous injection. The amt. of glycogen present before injection does not influence the decrease after injection. There is no relation between the decrease in the amt. of glucose in the blood and that of glycogen in the liver. The decrease of muscle glycogen is less than that of liver glycogen and is often slight in quantity. B. C. BRUNSTETTER

Adrenaline and the heart of the mollusc. O. V. HYKES. *Compt. rend. soc. biol.* **103**, 360-3(1930).—The heart action of *Physa fontinalis*, a fresh water mollusc, and *Pleurotrachea mutica*, a marine mollusc, was studied *in situ*. For the latter, dilns. of 1:10,000 to 1:100,000 were used; large doses lower the no. of heart beats per 30 sec., which become irregular, the heart finally stopping in diastole; moderate doses increase the frequency of heart beat, which is followed after a time by arrest. There is an increase in tonus. For the former animal, a diln. of 1:10,000 often causes a decrease in frequency of pulsations, followed by arrest of the heart. Dilns. of 1:1,000,000 cause an increase in tonus, strengthening of contractions and increase in frequency of heart beat. B. C. BRUNSTETTER

The effect of colloidal magnesium hydroxide and of sodium thiosulfate on leucocytes. J. LEBDUSKA AND F. CERVINKA. *Compt. rend. soc. biol.* **103**, 366-8(1930).—Phagocytosis of *B. coli* by leucocytes of horse blood is greatly increased (*e. g.*, 250%) by the addn. of 0.01-0.0001 *N* solns. of colloidal $Mg(OH)_2$ or $Na_2S_2O_3$. B. C. B.

The stimulating effect of adrenaline on muscular oxidation. ULF. V. EULER. *Compt. rend. soc. biol.* **103**, 445-6(1930); cf. *C. A.* **24**, 4858.—By use of Warburg's method, it was found that adrenaline in concns. from 10^{-8} to 10^{-14} stimulated oxidation in muscles. The increase in general was about 25%. To demonstrate this increase in muscles cut into fragments, the surrounding gas mixt. must be low in O_2; E. used 98% N_2 and 2% O_2. No increase was noted in whole muscles deprived of sympathetic innervation, but an increase occurs after the addn. of glycerophosphate. B. C. B.

The effect of adrenaline on acid-base equilibrium and on ionic calcium. M. CAHANE AND I. ORASTEANU. *Compt. rend. soc. biol.* **103**, 447-8(1930).—Repeated injections of adrenaline into dogs result in a compensated acidosis: the av. p_H of the blood before injection was 7.42, and after injection, 7.40; while the av. alk. reserve before injection was 41.77 and after injection, 36.48. After injections, oscillations of p_H were observed. The av. ionic Ca of the blood was 27.60 g. per 1000 before injection, and 31.90 g. per 1000 after injection. Adrenaline seems to act in the same manner as the thyroid on the acid-base equil., the effect of the thyroid being slow and lasting, and that of adrenaline, rapid and transient. B. C. BRUNSTETTER

Calcium chloride in the prevention of pleural effusions in artificial pneumothorax. LOUIS BOONSHAFT. *Am. Rev. Tuberc.* 21, 640–3(1930).—$CaCl_2$ prevents pleural effusions in artificial pneumothorax in almost all cases. It helps the absorption of pleural effusions when present, and obviates repeated pleural punctures. H. J. CORPER

Modern methods of narcosis. ERWIN DOMANIG. *Wiener klin. Wochschr.* 43, 1026–31(1930).—Brief descriptions are given of the use of $(C_2H_5)_2O$ *with* CO_2, of *solästhin*, N_2O, *avertin* and *pernocton*. Avertin is an amylene hydrate soln. of a $C_2H_2Br_3OH$ prepn. D. B. DILL

The influence of haloacetic acid poisoning on the solubility of muscle proteins. GUSTAV EMBDEN AND ERNST METZ. *Z. physiol. Chem.* 192, 233–44(1930).—The gastrocnemius muscle of frogs poisoned with $BrCH_2CO_2H$ and ICH_2CO_2H and protected from rigor by severing the plexus ischiadicus shows a marked change in the soly. of the proteins as compared with the normal muscle. In a phosphate buffer of definite normality and H-ion concn. the protein soly. is greatly diminished, the decrease amounting to about 20% of the normal value. A further decrease occurs after muscular work performed under elec. stimulation. The soly. changes are accompanied by alterations in the colloidal state of the muscle proteins. A. W. DOX

The behavior of benzenesulfonylmethyl-11-aminoundecylic acid in the animal body. TAKESHI HOSODA. *Z. physiol. Chem.* 192, 264–7(1930).—Two dogs were given subcutaneous injections of $PhSO_2NMe(CH_2)_{10}CO_2H$ as Na salt, one receiving repeated small doses over an 8-day period and the other receiving a 10 g. dose at one time. The product isolated from the urine was 54 and 57%, resp., of $PhSO_2NMe(CH_2)_2CO_2H$. No intermediate products were obtained. It is assumed that the breakdown of the C_{11} chain to a C_3 residue results from 4 successive β-oxidations. A. W. DOX

Further experimental contributions to the pharmacology of the acid oxidation products of cholesterol and of ergosterol. HANS SEEL. *Arch. exptl. Path. Pharmakol.* 150, 198–220(1930).—Unlike the neutral oxidation products, the acid oxidation products of cholesterol are moderately toxic, the lethal dose being 160–1000 mg. per kg. for frogs and 200–1500 mg. per kg. for mice. The most toxic is the chlorodicarboxylic acid $C_{27}H_{46}ClO_4$; the least, the satd. ketomonocarboxylic acid $C_{26}H_{44}O_3$; other acids formed are $C_{27}H_{40}O_8$, $C_{27}H_{42}O_5$, $C_{27}H_{44}O_6$, $C_{27}H_{44}O_4$ and $C_{27}H_{44}O_8$. There is necrosis at the site of injection, anemia of internal organs, intravasal hemolysis, intestinal hemorrhages and cessation of heart in systole. *In vitro*, these acids cause hemolysis at concns. of 1:2000–1:200,000 and an increase in the permeability of animal membranes. Irradiation of either cholesterol or ergosterol in the presence of O_2 causes the formation of water-sol substances with similar biological toxicity, but no antirachitic properties. H. E.

Madder as a chemical and biochemical reagent. ADOLF BAUER. *Arch. exptl Path. Pharmakol.* 151, 172–4(1930).—Growing rabbits, fed on madder, have a reddish tint in skeletal bones; urinary calculi are also red; both are due to combination of Ca CO_3 with the coloring material. H. EAGLE

Experiments in the absorption, distribution in the organism and excretion of rivanol, as well as its photodynamic effect. OTTO SCHAUMANN. *Arch. exptl. Path. Pharmakol* 151, 197–218(1930).—Injected intravenously, most of rivanol quickly disappears from the blood, to be excreted eventually in the bile and urine. In the body it is most concd in the liver and the tubuli contorti of the kidney, the organs concerned in excretion. It is not found in cerebrum or placenta; only minimal quantities can be demonstrated in the fetus or amniotic fluid after massive injections. Given perorally, it is quickly absorbed by carnivora only, to be taken up by liver and excreted in bile without reaching major circulation. Its toxicity, unlike that of porphyrin, is not increased by exposing the injected animals to light. H. EAGLE

The specific-choleretic action of cinchophen. KURT FRANKE. *Arch. exptl Path. Pharmakol.* 151, 219–31(1930).—Cinchophen and atophanyl cause as high as a three-fold increase in excretion of an hepatatrophic dye (eosin) through the bile in dogs, cats and rabbits, without increasing the secretion of bile. Larger quantities cause increased vol. of bile, but decreased dye excretion, because of a toxic action of the drugs upon liver cells. Decholin causes an increased flow of bile without affecting dye excretion. Cinchophen also hastens the diffusion of the dye *in vitro* from blood serum into a gelatin gel. H. EAGLE

The effect of thyroxine upon the regulation of body temperature. I. SUSI GLAUBACH AND ERNST P. PICK. *Arch. exptl. Path. Pharmakol.* 151, 341–70(1930).—Previous administration of thyroxine to rabbits and guinea pigs prevents the hyperpyrexia caused by subcutaneous injection of luminal sodium, but accentuates the hyperpyrexia induced by tetrahydro-β-naphthylamine-HCl or cocaine in rabbits. Thyroxine inhibits the hyperpyretic action of the former upon guinea pigs; they die with pulmonary

edema. Luminal given to rabbits treated with thyroxine prevents the synergistic action of the latter with tetrahydro-β-naphthylamine-HCl. Thyroxine has no effect upon the hypopyretic action of antifebrin and quinine; they can protect thyroxine-treated rabbits from a fatal dose of tetrahydro-β-naphthylamine-HCl. Morphine has no such protective action. H. EAGLE

Salyrgan diuresis and blood supply through the kidneys. ANNELIESE SCHLOB. *Arch. exptl. Path. Pharmakol.* **152**, 27–33(1930).—Ten % salyrgan injected intravenously (0.06 g./kg.) into dogs causes increased (twenty-fold) excretion of water and salts of about 1½–2 hrs. duration. Hedonal has very little effect upon this diuresis; chloralose inhibits or prevents it entirely, while "Numal" cuts it down to about ¼ its usual effect. The normal blood supply through the kidney is 1–7 cc. per g. Kidneys artificially perfused with blood show less diuresis upon injection of salyrgan than normal dogs; but the degree of diuresis seems to be independent of the blood supply. H. EAGLE

The acute effect of neoarsphenamine upon circulation. II. The cause of the circulatory effect. OTTO KRAYER. *Arch. exptl. Path. Pharmakol.* **152**, 50–66(1930).—Solns. of neoarsphenamine exposed to air undergo oxidation, with a shift toward acid reaction in 20–40 min., and probably, a coarsened state of dispersion, with a tendency to flocculate. Such oxidized solns. may ppt. more strongly with serum *in vitro* than the fresh soln. Injected intravenously, these oxidized solns. cause injury to the vessel walls, which occasionally leads to pulmonary edema, particularly in heart-lung prepn. There is increased resistance to blood flow, because of these histological changes in vessel walls, increased viscosity of circulating fluid, and possibly because of vasoconstriction. H. EAGLE

The partition of amino acids in the blood during chloroform narcosis and in anemic animals. Is there a correlation between the osmotic resistance of the red blood cells and the partition of the amino acids in the blood? A. SIMON AND E. ANNAU. *Arch. exptl. Path. Pharmakol.* **152**, 129–41(1930).—During $CHCl_3$ narcosis, blood amino acids usually increase, and the ratio of plasma amino acid to cell amino acid usually increases. There is no correlation between the osmotic resistance of red cells and their amino acid content. Following the removal of a large quantity of blood from rabbits and dogs, the $\frac{\text{cell amino N}}{\text{plasma amino N}}$ ratio usually decreases during the regeneration period. H. EAGLE

Investigations in the effect of yeast nucleic acids upon metabolism. HELMUTH REINWEIN. *Arch. exptl. Path. Pharmakol.* **152**, 142–59(1930).—Ingestion of nucleic acids by dogs causes decreased metabolism, occasionally even below the basal metabolic rate. Glycocoll has no effect upon blood amino acids. The specific dynamic effect of glycocoll meat can be decreased by nucleic acid. Pyrimidine nucleotides are quite toxic. H. EAGLE

The effect of adrenaline and of substances related to adrenaline upon vascular tonus. A. SCHRETZENMAYR. *Arch. exptl. Path. Pharmakol.* **152**, 210–28(1930).—As tested by the Ganter method in cats narcotized with urethan, adrenaline, ephedrine, ephetonine and tyramine, all cause increased vascular tonus, and not vasdilatation, as has been supposed. The action is due to the effect upon sympathetic nerve endings in the muscle layers of the vascular wall, and is therefore overcome by gynergen. The effects of these various drugs differ only quantitatively. H. EAGLE

Uzara. III. The convulsive effect of some uzara substances on the frog. O. GESSNER AND HERMANN SCHROTER. *Arch. exptl. Path. Pharmakol.* **152**, 238–49(1930); cf. *C. A.* **24**, 5068.—The toxic effect of uzara upon the frog is due both to some unrecognized substances not pptd. by tannin, and some glucosides and split products pptd. by tannin. Of the latter, one of the most active is the aglucone uzaridin, causing fibrillary twitchings and convulsions by its central action on the medulla oblongata, and strychnine-like reflex convulsions by its action on the spinal cord. Its split products are relatively ineffective. The chief alkaloid of uzara is the water-sol., cryst. uzarin, with a very similar effect; there is a second water-sol. glucoside uzaren. Uzarenin, a water-sol. aglucone, has only a paralytic effect. The only pharmacol. effect following the ingestion of uzara might be a tonic effect, as only a little is absorbed following peroral administration, and these highly active constituents are present in but slight concn. H. EAGLE

Investigations in the toxicology of sodium thiocyanate. GERT TAUBMANN AND RUDOLF HEILBORN. *Arch. exptl. Path. Pharmakol.* **152**, 250–6(1930).—The thiocyanate ion has a specific toxic action, quite apart from the CN ion, causing death in convulsions in 4–7 days when given to rabbits *per os* in doses of 0.1–0.2 g. per kg. twice a day. There is gradual anemia, albuminuria, and urobilinuria before death. No histological changes are found. It decreases the contractility of isolated muscle. H. EAGLE

Contributions to the pharmacology of gold compounds. I. B. v. ISSEKUTZ AND M. LEINZINGER. *Arch. exptl. Path. Pharmakol.* **152**, 288–305(1930).—A characteristic property of $NaAuCl_4$ is its great affinity to protein; it ppts. serum protein, agglutinates red cells, and inhibits the swelling of gelatin. Its diffusibility is very low, and its hemolytic activity is greatly inhibited by serum. It affects surface tension of water only slightly, is not lipoid sol. and is adsorbed by particles of India ink. $KAuCN_4$, on the other hand, is very capillary-active, slightly lipoid-sol. and freely diffusible. Its partition coeff. between red cells and water is 2, but between red cells and serum it is 1.1 because of combination with serum protein. It does not hemolyze red cells or inhibit swelling of gelatin, and is absorbed by charcoal, but only weakly by India ink. Sanocrysin has somewhat intermediate properties. An org. combination is not firmly bound and dissociates readily (electrolysis; reduction; H_2S in acid reaction). Such compds are not lipoid-sol., are readily adsorbed, and are bound by serum protein, particularly albumin. Only krysolgan was hemolytic; the others are only moderately bound by red cells. Liver perfused with solns. absorbs a large quantity. Like $AuCl_4$, such substances can inhibit blood coagulation. **II.** B. v. ISSEKUTZ AND Z. DIRNER. *Ibid* 306-17.—Au chloride is a protoplasmic poison for unicellular organisms; in vertebrates, however, it is bound by protein at the site of injection. Sanocrysin is less active upon bacteria, but can inhibit growth; it is more toxic for vertebrates. $KAuCN_4$ is most antiseptic, particularly against tubercle bacilli, probably because of the action of CN groups in inhibiting oxidation. It has no particular affinity for these bacilli. Its toxic action is very evident with frogs and rats, and is only slightly counteracted by Na thiosulfate or oxantin. Org. Au compds are very weakly toxic for bacteria, yeast or paramecia. Krysolgan and triphal are about as toxic as sanocrysin for frogs, while solganol is only about one-tenth as toxic. **III.** B. v. ISSEKUTZ AND I. MÉHES. *Ibid* 318-40.—Neutralized $AuCl_3$ has a tonotropic action upon isolated frog heart, causing a max irreversible systolic contracture in 1:2000 concn. Part of the Au is bound by the heart muscle; a similar effect is produced on gastrocnemius muscle. Microscopically, it is seen to act as an astringent. The salt is bound by blood serum, diminishing its effect upon the heart. Other Au prepns. have practically no effect upon isolated heart. Injected intravenously into frogs mesentery, it does not cause capillary paralysis. In the Laewen-Trendelenburg prepn. it causes vasoconstriction even in the presence of blood serum, with inhibition of edema formation. Injected into cats it causes a fall in blood pressure because of cardiac dilatation and decreased pulse vol., and increased frequency of respiration, with respiratory paralysis when more is used; cardiazole may remove the inhibition. Krysolgan and solganol act similarly, but are weaker. Au chloride increases the tonus of the isolated intestine; others are ineffective, with the exception of Au cyanide, which decreases tonus. H. EAGLE

Experimental cardiac damage by coronary vasconstriction and the action of drugs upon it. RICHARD ROSSLER. *Arch. exptl. Path. Pharmakol.* **153**, 1–35(1930).—From 0.1 to 0.3 cc. of pitressin causes extreme vasoconstriction of the coronary vessels of a dog in Starling heart-lung prepn. with resultant cardiac damage due to insufficient blood supply. The left ventricle is the first to be affected, causing an increase in pulmonary pressure; the right auricle may then be affected, causing complete insufficiency and auricular fibrillation. Complete recovery may follow if normal circulation is resumed in a short time. Second injections of pitressin have no effect, and tiny doses may protect against damage by a large dose. Previous administration of histamine, eutonon, morphine or papaverine does not protect against pitressin but 1-mg. histamine may restore a damaged heart by causing coronary dilatation. 0.1 mg. of adrenaline during the constriction causes cardiac death. Papaverine has the remarkable property of preventing subsequent damage by pitressin, as well as instantaneously stopping the pitressin contracture; this is due to both coronary dilatation and direct action upon cardiac muscle. Ephetonine is synergistic with papaverine in this protective action, causing powerful stimulation of musculature and increased coronary blood flow.
H EAGLE

The effect of certain analeptics upon the circulation. II. GREMELS. *Arch. exptl Path. Pharmakol.* **153**, 36-49(1930).—Cardiazole, coramine and hexetone are ineffective in decompensation involving the heart. Their therapeutic use is indicated solely in pure vascular insufficiency, as they cause increased blood pressure by acting upon the vasomotor center. H. EAGLE

Renorenal reflexes. PAUL BLATT. *Arch. exptl. Path. Pharmakol.* **153**, 67-78 (1930).—Mech. or elec. stimulation of the lower third of a ureter in cats or rabbits causes vol. changes in both kidneys. The reflex to the other kidney can be prevented by section of the cervical cord. Thermal or sensory stimulation of the skin of one side

of the abdomen causes vol. changes in both kidneys. A new oncometric method is described. H. EAGLE

The mechanism of the action of insulin. A. A. SCHMIDT. *Arch. exptl. Path. Pharmakol.* **153,** 79-93(1930). -A brief review of the recent literature is included. The confusing data as to whether the insulin effect consists of increasing the glycogen in liver or in muscles, or whether it causes glycogenolysis, or whether it affects oxidation of carbohydrates, are discussed. Data are presented which indicate that insulin causes glycogenolysis in the liver, and an increased absorption of glucose from the circulation by the muscles. H. EAGLE

Experimental investigations in the pharmacology of salyrgan. IV. Studies in the chemistry of salyrgan. KNUD O MULLER. *Arch. exptl. Path. Pharmakol.* **153,** 109-19(1930). - Salyrgan is a stable Hg complex, which does not liberate free Hg ions in soln. In acid reaction, it forms very slightly sol. salyrganic acid; even CO_2 gas suffices to bring about the change. Free Hg ions can be demonstrated in solns. of the salyrganic acid by measuring the potential against a Hg electrode. NaCl increases the soly. of the salyrganic acid, probably by forming a complex salt. Injected into the body, most of the salyrgan is excreted unchanged; in acid urine, it is excreted as the salyrganic acid-NaCl complex H. EAGLE

The influence of lecithin upon the carbohydrate metabolism. GUIDO IZAR AND SAVERIO CONSTANTINO. *Klin. Wochschr.* **8,** 1624(1930). - The subcutaneous injection of an aq. suspension of lecithin, lutein and cholesterol esters (Bioplastina) into adults causes a significant hyperglucemia, reaching a max. in 60-120 min., and returning to normal values within 5 hrs. HARRY EAGLE

Precipitates of colloidal silver in inflamed tissue. H. KOLLER-AEBY. *Kolloid-Z.* **53,** 101-2(1930). Colloidal Ag soln. injected intravenously ppts. Ag selectively on the inflamed tissue. The intensity of the pptn. is to a certain degree proportional to the degree of the inflamed condition. The ppt. is lacking in non inflamed tissues. ARTHUR FLEISCHER

The causation of lathyrism in man. H. W. ACTON AND R. N. CHOPRA. *Far East Assoc. Trop. Med. Trans. 7th Congress Brit. India* **3,** 444-8(1927); *Bull. Hyg.* **5,** 620.—A review of the theories given by other authors as to the cause. Feeding expts. and isolation of alkaloids indicate that the weed akti (*Vicia sativa*) contains an alkaloid which causes lathyrism. Akti, a common contaminant of *Lathyrus sativa*, misleads many by placing the cause on the latter. An injection of 50 mg. of the impure base from akti caused paralysis in guinea pigs. Ducks fed *Lathyrus sativa* without akti showed no bad effect, when 2 g. to the kg. was added paralysis occurred in 45 days. G. R. G.

The cryptotoxic power of various salts of saturated acids of the acyclic series. H. VINCENT. *Compt. rend.* **191,** 463-5(1930). V. has shown that Na oleate, palmitate and margarate neutralize completely in very small doses the microbe toxins, such as tetanus, diphtheria and dysentery toxins. V. then studied the Na salts of the fatty acids and found those with C_1, C_2 and C_3 non active. C_4, possesses antitoxic properties. The acid with C_5 has only a feeble power, and C_7 is still weaker. C_6, is quite active, C_8 is more active than C_7 but less than C_6. The power of C_9 is very weak. The Na caprate approaches the antitoxic activity of C_8. The undecylic acid has a very powerful cryptotoxic power, while C_{13}, C_{14}, C_{15}, C_{17}, C_{18} acids possess only very feeble antitoxic power because of their poor soly. Among the higher members, Na palmitate possesses considerable cryptotoxic power. The Na salts of satd. fatty acids in soln. possess very unequal cryptotoxic powers. This power does not seem to depend upon the no. of C atoms (odd or even) nor upon the m. ps. of the acids, nor upon the degree of soly. of the salt nor upon certain phys. properties (soly., consistency, etc.). F. R. G.

The action of adrenaline on the coronary arteries. S. DUCRET. *Arch. ges. Physiol. (Pflügers)* **225,** 680-5(1930). -The dilatation of the coronary arteries, which is induced by adrenaline, is max. when the artery is under a suitable state of tonus. This dilatation is also affected by p_H, $[Ca^{++}]$, temp., O_2 content of the perfusing fluid and varies with the age of the animal. $BaCl_2$ causes contraction of the coronaries. A. G.

The effect of paraldehyde, chloralose and amylene hydrate on the vagal action on the heart. F. PLATTNER AND C. L. HOU. *Arch. ges. Physiol. (Pflügers)* **225,** 686-93 (1930). -Paraldehyde, chloralose and amylene hydrate enhance the effect of vagal stimulation or of acetylcholine on the frog heart. Paraldehyde and chloralose inhibit the splitting of acetylcholine by heart exts. *in vitro*. ARTHUR GROLLMAN

The action of vagal materials and acetylcholine on the isolated ventricle of the frog heart. A. LÁNCZOS. *Arch. ges. Physiol. (Pflügers)* **225,** 710-20(1930).—Vagal materials (*i. e.*, the hormone which is supposed to be liberated by vagal stimulation) and

acetylcholine affect the ventricle most when the auricles are still attached and have no effect if part of the ventricle has been cut away. ARTHUR GROLLMAN

Action of cinchona and certain other alkaloids in bird malaria. JOHN A. GOODSON, THOMAS A. HENRY AND JOHN WM. SCOTT MACFIE. *Biochem. J.* **24**, 874–90(1930).—Among the alkaloids tested on canaries infected with *Plasmodium inconstans*, only those of the cinchona series were of value. Among the natural cinchona alkaloids, the most active was hydroquinone. Activity is restored to quitenine and the analogous carboxylic acids were derived from quinidine, cinchonidine and cinchonine, by esterification. BENJAMIN HARROW

Comparison of the effects of arginine and thyroxine upon tumour growth-rate in the mouse. ESMÉ GILROY. *Biochem. J.* **24**, 1181–7(1930); cf. *C. A.* **24**, 5061.—Thyroxine retards the rate of tumor growth. The substitution of arginine for thyroxine causes a renewal of rapid growth. BENJAMIN HARROW

Action of insulin on the glycogen distribution in normal animals. MAURICE W GOLDBLATT. *Biochem. J.* **24**, 1199–1209(1930).—Liver glycogen increases after the injection of insulin into starving rabbits. Under the conditions described, it is considered that glycogen formation from endogenous sources is definitely increased. BENJAMIN HARROW

Pharmacological action of certain phenol esters, with special reference to the etiology of so-called ginger paralysis. (Second report.) MAURICE I. SMITH, E. ELVOVE AND W. H. FRAZIER. *U. S. Pub. Health Rept.* **45**, 2509–24(1930); cf. *C. A.* **24**, 4849.—A pharmacol. study of the action of the phosphoric acid esters of the phenols and some of the cresols has shown conclusively that tri-*o*-tolyl phosphate, and in so far as the present evidence goes, it alone, can produce in exptl. animals a sp. type of motor paralysis of the extremities in every sense comparable with that which occurred recently in human victims who drank of an adulterated fluidext. of Jamaica ginger. Some of the differences in species susceptibility to tri-*o*-tolyl phosphate previously reported appear now to be due to differences in its absorbability from the alimentary canal. Certain other differences in species susceptibility cannot yet be accounted for on the basis of our present limited knowledge of the manner of action of this poison in the animal body. Pharmacol. evidence has been presented to show conclusively that the adulterated fluid ext. of Jamaica ginger used for beverage purposes, resulting in an epidemic of partial paralysis, contained tri-*o*-tolyl phosphate to the extent of about 2%. The chem. evidence obtained confirms the pharmacol. evidence and fully harmonizes with it. The etiologic relationship of tri-*o*-tolyl phosphate to the recent epidemic of so-called ginger paralysis is thus definitely established. J. A. KENNEDY

Nitrobenzene poisoning with general blood coagulation and hemorrhagic encephalitis. EDUARD GÜNTZ. *Deut. Z. ges. gericht. Med.* **15**, 461–9(1930).—Nitrobenzene, administered to bring on menses, produced a narcotic-like unconsciousness from which the patient awoke spontaneously. The following day she became cyanotic and icteric and experienced difficulty in breathing. Post-mortal examn. showed complete blood coagulation and an hemorrhagic encephalitis. FRANCES KRASNOW

The distribution of arsenic in the body especially after many poisonous doses. S. BLUMENFELDT. *Deut Z. ges. gericht. Med.* **15**, 501–21(1930).—Analyses of As in the stomach, intestines and liver fail to give a lead as to whether one or many doses have been taken. If As poisoning is suspected, the hair should be analyzed because there is an accumulation in the hair. If the stomach contains large quantities of As, whereas only a little is found in the hair, the case is one of acute As poisoning. F. K

Poisoning by autumn colchicum seeds. O MEZGER AND W. HEESS. *Deut Z. ges. gericht. Med.* **15**, 522–8(1930).—The animals (mice and cats) showed poisoning which reached fatality very gradually (a characteristic of colchicum). Besides this the animals suffered severe vomiting and diarrhea and on autopsy there was inflammation of the stomach and intestines. FRANCES KRASNOW

Parathyroid and fluoride hypocalcemia. REBECCA GERSCHMANN. *Ann. farm bioquim.* **1**, 77–84(1930).—G. confirmed that extirpation of the thyroid and parathyroid glands occasions a reduction in the blood Ca. The onset in the reduction is prompt, and the diminution may continue for 48 hrs. The injection of 30 mg. of NaF per kg. of body weight produces a reduction in the blood Ca in 24 hrs. At the end of the 3rd to 4th hrs. a rise becomes manifest which lasts for 24 hrs., never reaching the original Ca content. The hypocalcemia is usually accompanied by an increase in the blood P. In parathyroidectomized dogs the reduction in the blood Ca is greater than in those receiving F, and no rise in the Ca is observed in the former. G. assumes that the function of the parathyroid gland is to maintain the blood Ca at a normal level. B. S. L.

The parathyroid and the hypocalcemic curve. REBECCA GERSCHMANN. *Ann.*

farm. bioquim. **1**, 85–8(1930).—Ca solns. were injected into normal and operated dogs. The blood Ca curves were identical in all animals so far as the general character of the curves is concerned, but the return to the normal Ca blood content was slower in the dogs parathyroidectomized within 24 hrs. of the experimentation. B. S. LEVINE

Potassium thiocyanate in the treatment of hypertension. LEO M. MAGUIRE. *U. S. Vet. Bur. Med. Bul.* **6**, 978–9(1930).—Four cases were treated with the drug. The cases had essential hypertension carefully diagnosed. As a result of the drug administration the blood pressure was reduced and there was a general feeling of well-being, except when the blood pressure was reduced too low. Discontinuance of the drug administration was followed by a return of hypertension to the original level. Conclusions: KCNS reduces arterial hypertension. It may be of marked value in impending or actual cerebral hemorrhage. Its effects are not permanent. B. S. L.

The influence of synthetically prepared thyroxine on the growth of explanted tissue. TOMOSADA SATO. *Acta Schol. Med.* **13**, 39–44(1930).—Earlier studies have shown that a single hormone in the body is not independent in its action. Expts. on cultivated tissue have shown that thyroid hormone has an important influence on the growth of tissue, and S. has undertaken to det. the effect of synthetic thyroxine. Heart tissue from chicken embryo, lung from rabbit embryo and chicken myxosarcoma were used. For pure fibroblast, pieces of heart from chicken embryo 8 days old were employed. Fragments about 0.5 min. in diam. were cultivated in homologous plasma, embryo tissue fluid or milk ext. contg. medium. Carrel culture flasks were used and solid and fluid media were tried. Increase in growth was measured by a vertical projection app. and a planimeter every 24 hrs. for about 7 days. The synthetic thyroxine accelerates the growth of heart tissue and fibroblast from chicken embryo and lung tissue from rabbit embryo. In suitable concn. it accelerates the growth *in vitro* of chicken myxosarcoma. G. H. W. LUCAS

Some recent chemotherapeutical investigations. FRANK L. PYMAN. *Chemistry and Industry* **49**, 757–60(1930).—A review. G. H. W. LUCAS

Electrographic investigation on the copper action on the isolated heart and ventricular strips of the frog. KIKUO OGUI. *Folia Pharmacol. Japon.* **10**, No. 1, Opera orig. 1–10(1930)(in German).—Cu is a very strong heart poison. Evidence shows that it has a depressant action, but O. began his expts. to observe any changes in the electric processes in the heart as measured by the electrocardiograph. Expts. were conducted by the Straube moist chamber method. From the electrogram of the isolated heart it is apparent that the P-R interval is unchanged. The ventricular electrogram shows a lowering of the R and T wave with a weakening of ventricle contraction and a lengthening of the T wave with a diminution in frequency. The R wave point broadens. The T wave is generally lower, and undergoes such peculiar changes as are seldom seen. The form of the electrogram is not influenced by atropine. Changes in ventricular strips are practically those observed in the whole heart in the electrogram and mechanogram. However, with the strips, the rise in frequency is sooner observed. The strips are poisoned more quickly. O. enters into a long discussion of the changes occurring in the various waves of the electrogram and the electrical changes occurring in the heart during Cu poisoning. References and electrograms are given. G. H. W. LUCAS

The pharmacology of urochloralic acid with special regard to the diuretic action of the sodium salt of this acid. HIRONDO MATSUSHIMA. *Folia Pharmacol. Japon.* **10**, No. 1, 23–48, Breviaria 2–3(1930).—Camphor, phenol, chloral hydrate, menthol, thymol, BzOH, etc., after combining with glucuronic acid in the body, are excreted in the urine in this non-toxic form. The diuretic action of urochloralic acid was studied along with the other reactions in the body. In small quantity it causes an increase in tonus in the rabbit heart and thus a decrease in contraction height. In large doses the tonus falls and the contraction strengthens. Changes in the rate are scarcely perceptible. Isolated ear and coronary vessels in rabbits and vessels in the extremities in frogs are dilated. A diuresis occurs in rabbits together with a small rise in blood pressure. There is evidence of a hydremia. Kidney vessels are dilated. The action is peripheral, for the phenomenon is present in rabbits after section of the splanchnics and the vagus in the neighborhood of the colliac ganglion. Its diuretic action is evident in toads, even after ligature of the portal vein. G. H. W. LUCAS

The difference of action of atropine and of adrenaline on the rabbit intestine excited by digitalein and strophanthin. MASAO TAKEDA. *Folia Pharmacol. Japon.* **10**, No. 2, 147–57, Breviaria 9(1930).—A large no. of parallel expts. have been carried out on strips of rabbit intestine stimulated by Ba, digitalein and strophanthin with atropine and adrenaline. The depressant action of atropine on the intestine after the stimulation by the above poisons is weaker, the stronger the exciting effect of the poison, and

after large doses is actionless. The adrenaline effect is also diminished after the poisons. The adrenaline effect is not noticeable when the intestine is intensively stimulated. If the diminution of the adrenaline effect is evident, Ba shows itself the strongest, strophanthin is weaker and digitalein is weakest, which is evidence that the manner and mechanics of the action of these poisons are not quite similar. The adrenaline effect against these drugs is essentially the same as against pilocarpine, acetylcholine and physostigmine, but the atropine effect is different. The sympathetic stimulation by direct excitement of the intestine musculature still is able to exert an important influence. G. H. W. Lucas

Pharmacological study on the geometrical isomerism of deoxidized tetrahydrosinomenine in comparison with sinomenine. Hiroshi Koika. *Folia Pharmacol. Japon.* **10**, No. 2, 158-74, Breviaria 10(1930). -The geometrical isomers of deoxidized tetrahydrosinomenine form amorphous brownish black salts with HCl, which are easily sol. in water. Sinomenine produces in frogs, mice and rabbits increased reflex excitability, convulsions and following this, disturbance of motility and respiratory paralysis The increased reflex action of sinomenine is much weakened in the reduced product and thereby the depressant action is much in the foreground. The reduced product is more poisonous. Vessels in the frog's leg and ear vessels in the rabbit are first dilated by perfusion with this product and then constricted with weak solns., but are always constricted by strong solns. In rabbits, a transient decrease in blood pressure is produced, but the heart is only damaged by large doses The respiratory center is stimulated by small doses in various animals, but is depressed by large doses. The reduction product depresses the automatic movements of the surviving rabbit intestine and uterus. After fever puncture in rabbits, it reduces fever. The oxidase action on fresh plant cells is promoted by a small quantity of the poison, but hindered by large quantities. Paramecia are injured by it G. H. W. Lucas

Physiological investigation on the embryonic chicken intestine. Hidenari Machii *Folia Pharmacol. Japon.* **10**, No. 2, 175-90, Breviaria 11(1930). Embryonic chicken intestine 4 to 20 days old was fed in physiol. salt soln., in Ringer's, Locke's and Tyrode solns. at temps of 35–43°, and spontaneous movements were observed through a lens The behavior, as well as the movements, can be sepd. into 5 parts. The isolated intestine remains almost without movement until about the 6th embryonic day The opt. temp. for spontaneous movement is 40. In later study it was found that in Locke or Tyrode nutrient media an opt. temp. of 40-41° was observed in Locke soln. from the 14th day, and in Tyrode from the 12th. The greater the departure of the exptl. temp. from the opt. the more unfavorable was the effect on the intestine movement. In Tyrode soln. the movements were strongest, in Locke a little weaker, in Ringer still weaker and weakest in the physiol. saline *Ibid* 191-201, Breviaria 12 The effect of drugs on isolated chicken intestine nourished in Tyrode soln. at 40° was observed by use of a lens. Pilocarpine in a 6-day embryo produces no stimulation. Movement is seen first in a 7-day embryo and the pilocarpine stimulation is evident after that At 7 days the adrenaline effect is almost nil, but at 8 days is quite apparent, and is always intense. Nicotine always shows a stimulation at 6 days, and with the progressive evolution of the intestine, becomes more sensitive. Ba is active at 5 days. From these data it is apparent that nerves as well as musculature in the embryonic chicken intestine increase in their sensitivity to drugs with their development G. H. W. Lucas

Neutralizing action of cystine against arsphenamine and quicksilver intoxications. Sanaye Fujino. *Folia Pharmacol. Japon.* **10**, No. 2, 202-62, Breviaria 12 3(1930) - Cystine is believed to be the only amino acid contg. S. After varying amts. of cystine ($^1/_2$, $^1/_3$, $^1/_5$ or $^1/_{10}$ of the lethal dose) were injected into the abdominal cavity, lethal doses of arsphenamine or Hg were given intraperitoneally or intravenously after a certain length of time. Cystine showed a marked neutralizing action after 6 to 54 hrs., and the majority of animals survived when it was given 24-54 hrs before arsphenamine or Hg. Histological findings after $^1/_{10}$ to 2 or 3 times the lethal dose of cystine showed after large amts. a hyperemia in the kidneys, a slight dilatation of uriniferous tubuli and Bowman's capsules. Small quantities of cystine showed little change. The amt. of ethylsulfuric acid in the urine was the same whether cystine was injected prior to arsphenamine and Hg or not. Glutathione was estd. in liver, pancreas, kidneys and blood 1 to 72 hrs. after cystine injection. A great increase was found in the liver, reaching a max. in 24 hrs. Pancreas and kidneys showed some increase, reaching a max. in 24 hrs. also, but blood was unchanged. There seems a close relationship between the amt. of glutathione in the liver and the intensity of the neutralizing action *Ibid* 263-87, Breviaria 14.—It was suggested by the above investigation, that cystine changed to glutathione in the body, and this fact led to expts. with cysteine which more

closely resembles glutathione, in a series similar to that with cystine. Its neutralizing action was quite obvious. Its action against arsphenamine and Hg was most intense when the 2 drugs were given in a mixt. or simultaneously. The action of cysteine is quite different from cystine. G. H. W. LUCAS

Antiphlogistic action through drugs. HIROSHI SUZUKI. *Folia Pharmacol. Japon.* 10, No. 3, 289–308, Breviaria 15(1930).— Inflammation was produced in rabbits' eyes by placing in the conjunctival sac, oil of mustard, antipyrine, quinine, eryeon, salicylic acid and sinomenine and rabbit serum acted antiphlogistic to the mustard inflammation, while casein, streptococcus serum, streptococcus vaccine and staphylococcus vaccine showed practically no action. G. H. W. LUCAS

Antiphlogistic action through drugs to the inflammation produced through heat and cold. HIROSHI SUZUKI. *Folia Pharmacol. Japon* 10, No. 3, 309–32, Breviaria 15–6 (1930). —Inflammation was produced in rabbits' eyes by the instillation of hot olive oil at 180° into the lower conjunctival sac. Antipyrine, quinine, eryeon and salicylic acid, injected subcutaneously prior to the olive oil treatment, possessed antiphlogistic action. Sinomen and rabbit serum have only a slight action in the initial stage, but in later stages they were quite efficient. Streptococcus serum showed some action in early stages. Casein, streptococcus and staphylococcus vaccine were almost valueless. Following inflammation produced by EtCl, practically all of the above drugs showed only a weak antiphlogistic action G. H. W. LUCAS

The pharmacological action of carpainic acid and the ethyl esters of carpainic acid. KENJON KYU. *Folia. Pharmacol. Japon.* 10, No. 3, 333–60, Breviaria 16–7(1930).— Carpainic acid and the Et ester have been prepd. by Barger from carpain. It has an imino group in which the N and the carboxyl group form a lactone ring. Both the acid and the ester depress the central nervous system and cause slight convulsions in mice and rabbits. In frogs the acid only is active. The m. l. d. of the acid for frogs is 2 mg. per g., for mice 10 mg. per g.; whereas 0.5 mg per g. of the ester is fatal to both. In rabbits 200 mg. of the acid per kg. intravenously shows no effect, but 30 mg. per kg. of the ester is fatal. The ester is also very toxic to the respiratory center, 10 to 15 mg. per kg. causing cessation of respiration. The acid does not affect blood pressure in rabbits, but the ester always produces a fall, because it is a heart poison. On frog muscle, the ester is about 10 times as depressing as the acid. Both drugs constrict vessels in frogs' hind legs, but dilate ear vessels in rabbits. Both drugs act directly on smooth muscle organs and earthworm muscle. The earthworm muscle is stimulated, whereas rabbit intestine is depressed by small doses. Small and moderate doses stimulate rabbit uterus but large doses depress it In a nerve muscle prepn. of the frog gastrocnemius the motor nerve endings and the muscle are paralyzed in the same manner, the ester being twice as active as the acid. Carpain and the ester are about equal in their action The weak action of the acid is due to the presence of the carboxyl group G. H. W. LUCAS

The detoxication of adrenaline through the reticulo-endothelium apparatus. I. TOKANOSUKE UEMORI. *Folia Pharmacol. Japon* 10, No. 3, 361–79, Breviaria 18 (1930). Rabbits were injected with India ink in the ear vein or the mesenterial vein, and 8 hrs. afterward the effects of adrenaline on blood pressure were accurately measured The min. active dose of adrenaline had diminished after administration of the ink, the intensity of the rise in blood pressure was increased, and increased still more after successive injections of the ink. This adrenaline action is closely related to the amt of ink particles in the reticulo-endothelium system. Greater adrenaline activity is obtained by injection in the ear vein than in the mesenterial before the blockade by the ink; the latter greater effect is produced by injection in the mesenterial vein If the Congo red index, according to *Adler* and *Reimann*, be estd. in normal rabbits and in others treated once or four times with ink, it is noticed that the index rises a little in the treated ones. The C particles in the reticulo-endothelium system influence in varying degrees adrenaline detoxication and Congo red index. G. H. W. LUCAS

Experimental study on the influence of poisonous gases upon the pigment-excreting function of the liver and the kidneys. I. Carbon monoxide. HYAKUICHI YAGATA. *Japan. J. Gastroenterology* 2, 169–77(1930). Adult rabbits were forced to inhale CO. The rate of elimination of coccin 2B, azorubin s, eosin a, phenolsufonephthalein and azococheneal through the bile and urine was then detd. colorimetrically. The CO poisoning decreases the powers of elimination of both the kidneys and liver. Bile decreases in amt. and turns brown during inhalation of CO but reverts to normal after inhalation stops. If the liver is injured with $CHCl_3$ or P in rabbits the excretion of dyes by the kidneys is increased but this compensating function fails after CO poisoning. The liver, although poisoned, increases its excretion. If kidney poisons such as K

chromate or U nitrate are injected before CO is inhaled, there is no compensation. Both organs fail in the dye secretion. The excretion of dyes provides addnl. evidence that CO inhalation does not cause chronic poisoning. C. M. McCay

The pharmacological action of pyrrole and of pyrryl alkyl ketones. V. Experiments on striated muscle. Angelo Rabbeno. *Arch. sci. biol.* (Italy) **15**, 107–46(1930); cf. *C. A.* **25**, 145.—Pyrrole provokes in striated muscle (frog gastrocnemius) a double lasting contraction, characterized by a rapid reversible phase in which the muscle maintains its excitability (contracture) and by a second slow irreversible phase in which the muscle becomes inexcitable (rigidity). The pyrryl alkyl ketones provoke a contraction in which the 2 phases are graphically fused; among these the butylpyrrole is the most active. The contraction by pyrrole which takes place in an analogous manner in the homologous muscles is increased by curarization especially during the rigidity, while it is not influenced by atropine or eserine. The contracting action of nicotine is added to that of pyrrole. Pyrrole and its ketone derivs. diminish the capacity of the muscle to do its work. By the combined action of pyrrole (also pyrryl alkyl ketones) and heat, contracture takes place at much lower temps. than the controls (heat alone). The terminal contraction, however, is not hastened. The heat contracture may be preceded, according to the dose of the drug used, by a precontractural contraction or by an initial lengthening. It is suggested that the seat of action of these drugs is in the muscular substratum and not in the myoneural elements; they do not act on the connective structure of the muscle. Peter Masucci

Gold salts in diabetic patients with tuberculosis. Maurice Villaret, L. Justin-Besançon and René Cachera. *Presse méd.* **38**, 218–9(1930).—Au salts have an unfavorable effect. A. E. Meyer

The cholagog action of aromatic acids. Etienne Chabrol, R. Charonnet, Maurice Maximin, J. Porin and M. E. Piettre. *Presse méd.* **38**, 433–6(1930).—The bile secretion is increased by the action of naphthoic acid, 3-hydroxy-2-naphthalenecarboxylic acid, Na *m*-hydroxybenzoate and phloroglucinol. The action of Na salicylate is uncertain. $C_6H_5CO_2Na$, Na *p*-hydroxybenzoate, tribromophenol and tetraiodophenolphthalein are inactive. Conclusion: The CO_2H group is essential for the effect, but a second CO_2H group has no further influence. The combination of several nuclei, increase of the mol. wt. and presence of OH groups increase the effect, but it is not a strict law. A. E. Meyer

Acute bismuth poisoning. Rodolfo Dassen and Juan C. Rey. *Semana méd.* (Buenos Aires) **1930**, II, 1152–7.—A fatal case of poisoning after a single injection of a therapeutic dose of Bi is reported. A. E. Meyer

The barbituric derivatives in the treatment of tetanus. Raúl F. Vaccarezza, Carlos A. Videla and José Peroncini. *Semana méd.* (Buenos Aires) **1930**, II, 1177–91.—The diethylallylisopropylbarbiturate of Et_2NH (somnifen) was used in 25% soln. for intravenous injection of 2 cc. up to 3 times a day. Besides, antitoxin was given. A remarkable suppression of the grave symptoms was obtained. A description of 7 cases is given. A. E. Meyer

Pharmacological action of sea water injected intravenously. A. Rabbeno. *Arch. ital. biol.* **83**, 73–85(1930); cf. *C. A.* **24**, 892.—Intravenous injection of sea water is toxic, 144 cc. per kg. being sufficient to kill a rabbit. As the rate of injection increases the lethal dose also becomes greater. The toxicity curve resembles very much that of a 0.598 *M* soln. of NaCl, though the toxicity of the latter is lower. The production of urine is increased and the per cent of Cl progressively rises. There was no glucose in the urine, and even where glucosuria existed prior to the injection it diminished and finally disappeared altogether as the injection proceeded. A soln. of NaCl, other things being equal, exerts a much stronger diuretic action and causes a greater Cl excretion than the sea water. S. Morgulis

Clinical investigations into the effect of intravenous injection of insulin. III. The blood-sugar curve in diabetics. Th. E. Hess Thayssen. *Acta med. scand.* **73**, 408–24 (1930); cf. *C. A.* **24**, 2195, 4866, 5380; **25**, 148.—In mild cases of diabetes the blood-sugar curve following the intravenous injection of 12 units of insulin is normal. The curve presents a more or less rapid drop to the lowest level, the assimilation curve, which is followed by a sharp rise, the restoration curve. In severe diabetics the curve becomes more abnormal as both the assimilation and restoration lines tend to flatten out. The flattening of the assimilation line is due to the fact that in the diabetics the lowest blood-sugar level is reached slower, this delay apparently increasing with the severity of the condition. The assimilation index, by which is meant the amt. of glucose assimilated per min. expressed in per cents of the initial blood sugar value, varied from 2.1 to

0.3, and is independent of the initial sugar level, presence or absence of acidosis, or fasting for 3 days. It is lower the more severe the diabetic condition. Patients with an assimilation index of 2.1–1.1 are able to assimilate sufficient carbohydrate and enough calories in their food without insulin. Patients with an assimilation index of 1.0–0.7 required a moderate dose of insulin to keep their urine free of sugar or acetone on the same diet. When the assimilation index was 0.7–0.3 massive doses of insulin were needed to keep the morning urine sugar free or to cause acidosis to disappear. S. M.

Clinical investigations into the effect of intravenous injection of insulin. IX. Gastric secretion in normal individuals. KAJ ROHOLM. *Acta med. scand.* **73**, 472–92 (1930).—Studies of the fasting gastric content obtained by continuous suction have been made on a no. of patients with normal stomach function. In 9 patients the amt. of secretion, free acid, total acid and pepsin were detd., while in 16 patients the same detns. were carried out after an intravenous injection of 12 international units of insulin. The insulin stimulated the gastric secretion both quantitatively and qualitatively. In 13 of the 16 subjects the acidity curve runs a typical course, reaching a max. 1 hr. after the insulin injections. By regulating the blood sugar level it has been possible to show that the gastric secretion must be regarded as a hypoglucemic symptom, the level of 40–50 mg. % being the threshold value at which the gastric secretion is produced.
S. MORGULIS

Biochemistry of iodine and arsenic pyridone derivatives. A. BINZ, C. RÄTH AND K. JUNKMANN. *Biochem. Z.* **227**, 200–4(1930).—Pyridine and 2-pyridone have the same toxicity. The introduction of H_3AsO_4 in the 5 position or of AcH in the NH group detoxicates the compds., I in the 5 position makes 2-pyridone somewhat more toxic but the addn. of AcH in the NH group gives rise to an I compd. which is even less toxic than the As deriv. S. MORGULIS

Influence of potassium, calcium, strontium, barium and magnesium salts on the respiration of isolated kidney tissue. JESAIAS LEIBOWITZ. *Biochem. Z.* **226**, 338–54 (1930).—The addn. of Ca salts to the NaCl either increased the respiration or had no effect, but in no instance did it produce inhibition, the kidneys of different animals responding in a characteristic manner. In every instance the Ca in the nutritive medium acted against the lowering of respiration resulting when the tissue is kept in the nutritive medium. Sr, Ba and Mg also stimulate respiration and more or less in the same degree as Ca. Optimum results were obtained with 30% of the "normal" addn. of $CaCl_2$, $SrCl_2$, $BaCl_2$ or $MgCl_2$. Even increasing the concn. of these salts 5 times had practically no effect, except with $BaCl_2$ when the respiration dropped 6–12%. No marked effect was exerted on the respiration by the addn. of K to the NaCl soln., not even when the K concn. was increased several times. K protects the respiratory function similar to the Ca, but the preserving power of Ca is greater than that of an equimol. concn. of K. The addn. to Ringer's soln. of $MgCl_2$ in concns. of 0.001 to 0.005 % always stimulated respiration; concns. 0.04 to 0.10% generally exerted an inhibiting effect on the respiration, while concns. 0.01–0.02% sometimes stimulated and sometimes inhibited it. The concn. of 0.01% $MgCl_2$ is regarded as being intermediate between the respiratory stimulating or inhibiting action of $MgCl_2$. The stimulating effect of Ca, Sr, Ba and Mg ions was shown to manifest itself at p_H 6.9 to 7.8, and this is also true for the action of K. S. MORGULIS

Parental resorption of colloids. III. M. MURATA. *Biochem. Z.* **226**, 457–61 (1930). -Intravenous injections of diastase, like that of urease, cause a rise in the blood-diastase content lasting several hrs. Diastase injected subcutaneously is not found in the blood serum, nor does it pass into the blood following intraperitoneal injection of even large doses. S. MORGULIS

The bilirubin-forming ability of the surviving spleen from dogs treated with thorium dioxysol. SUSUMU TSUNOO AND HIDEO NAKAMURA. *J. Biochem* (Japan) **12**, 133–8 (1930).—The reticulo-endothelial system of dogs was blocked by means of intravenous injections of a 5% ThO_2 colloidal soln. in combination with 5% glucose. The exptl. results show that this affects very markedly the ability of the spleen to produce bilirubin.
S. MORGULIS

Further studies on the influence of splanchnectomy on the sugar-excretion threshold. YOSHIO IWANAGA. *J. Biochem.* (Japan) **12**, 195–205(1930).—Double splanchnectomy leaves the threshold of sugar elimination almost unaltered. If the operation is not complete a rise in the sugar-excretion threshold may be produced because of the irritation of the sympathetic which can be abolished entirely by ergotamine. Acetylcholine raises very markedly the blood sugar value as well as the sugar-excretion threshold in normal animals, but following complete sectioning of the splanchnics acetylcholine

loses this effect, which leads to the conclusion that this substance produces its action through central stimulation of the sympathetic. S. MORGULIS

The use of sodium ricinoleate in bacterial hypersensitiveness of the intestinal tract. ROGER S. MORRIS AND STANLEY E. DORST. *Ann. Internal Med.* **4**, 396–7(1930).—All of 70 patients obtained marked relief and 40 became symptom free. J. T. M.

The intrinsic rhythm of the turtle heart studied with a new type of chronograph, together with the effects of some drugs and hormones. ALFRED L. LOOMIS, E. NEWTON HARVEY AND C. MACRAE. *J. Gen. Physiol.* **14**, 105–15(1930).—The effects of adrenaline, ephedrine, thyroxine, α- and β-pituitary hormone, insulin, nicotine and atropine on the turtle heart are described. Temp., p_H and O_2 supply were held const. for 36 hrs. Methods and app. are described. C. H. RICHARDSON

Therapeutic use of urease in phosgene poisoning. SVEN E. SVENSSON. *Svensk Farm. Tids.* **34**, 493–7, 509–14, 565–7(1930).—Urease in aq. ext. from soy bean loses its activity rapidly. By adding 1 drop C_6H_5Me per 50 cc. ext. the activity is held 7 days Animals poisoned with $COCl_2$ respond favorably to intravenous injections of urease exts. preserved with C_6H_5Me. The antidote action is hastened by simultaneous injection of $CO_2(NH_2)_2$. A. R. ROSE

Further studies on the effects of the rectal administration of insulin. Contribution to the knowledge of absorption in the terminal tracts of the intestine. G SALVIOLI AND G CORBINI. *Pediatria Rivista* **38**, 921–36(1930), cf. *Ibid* **37**, No. 14.—Introduction by rectum of small doses of insulin dild. with saline soln. into the terminal part of the intestine produced a lowering of the blood sugar in nurslings and small infants; with regard to duration and intensity the hypoglucemia was comparable to that produced by subcutaneous injection of insulin. With older children and adults the rectal administration was effective only when the insulin was introduced into the higher levels of the intestine. The therapeutic results obtained with insulin administration by rectum in 36 children were not encouraging. G SCHWOCH

Investigations on the metabolism in the circulatory shock. III. The potassium and calcium level in the peptone shock. E. SCHIFF, H ELIASBERG AND A. MAZZEO *Pediatria Rivista* **38**, 1158–61(1930); cf. *C. A* **24**, 4862.—Five dogs fasting for 24 hrs., in which a peptone shock had been produced, showed a 2–4 fold increase in serum K The serum Ca was slightly or moderately augmented. The increases were very distinct 5 min. after injection of the peptone. The values returned to normal after 30 to 60 min. G. SCHWOCH

Investigations on the physiological action of cerebrin. R. MONTEZERMOLO. *Rass clin. terap. sci. affini* **29**, 1–18(1930).—M. studied the effect of cerebrin injections on the growth, blood picture and wt. and lipoid content of various organs of rabbits. Subcutaneous injections daily of 0.05 g. cerebrin in 1 cc. physiol. NaCl soln. were administered to 2 young male rabbits (I); the total amt. of cerebrin injected was 1.5 g. Two other rabbits (II) were injected daily with 0.1 g. cerebrin; in these animals the total amt. injected was 3 g. Two rabbits served as the controls The animals were sacrificed 8 days after the last injection. The cerebrin injections caused the following changes The growth was slightly accelerated in I and distinctly retarded in II. The no. of red blood cells was considerably augmented; the increase was proportional to the quantity of cerebrin injected and amounted to more than 2 millions in II. This increase was maintained even after cessation of the injections. The hemoglobin was increased, though not in proportion to the increase in erythrocytes. A leucocytosis appeared which increased with the increasing no. of injections and which was still noticeable 3–5 days after cessation of the injections In the leucocyte formula the ratio between lymphocytes and polynuclear cells, which was 50:43 5 in the controls, was changed to 71.25:25 The blood sugar remained unaltered. The wt. of all the organs examd. differed considerably from that of the controls; these changes were proportional to the quantity of cerebrin injected. The most conspicuous increases were observed in spleen, adrenals, thyroid, kidneys and testicles. The wt. of the liver was slightly increased in I, but was diminished in II. The chem. analysis of the brain revealed that lecithin and cerebrin were augmented, while cholesterol was diminished. With the liver an increase in fats and lecithin and a diminution of cholesterol was observed. Numerous tables, graphs and references are given. G. SCHWOCH

The synergism between calcium and magnesium. Experiments on the frog heart. ALBERTO CABITTO. *Rass. clin. terap. sci. affini* **29**, 57–62(1930). A frog heart was isolated, mounted on a Straub cannula and perfused with Ringer soln. Addn. of 0.01% $MgCl_2$ caused an increase in the intensity of the systoles. A similar increase was noted on addn. of 0.01% $MgCl_2$ to a Ringer soln. rich in Ca ($CaCl_2$ 0.07%). Addn. of $MgCl_2$

to Ringer solns. contg. an insufficient quantity of Ca restored the normal cardiac activity. The cardiac function, which had been arrested by perfusion with Ca-free Ringer soln., was not restored when 0.005–0.06% $MgCl_2$ was added. However, when to such a Mg-contg. Ringer soln. was added a very small quantity of $CaCl_2$ (0.005%), which in itself was insufficient to restore the cardiac function, the heart systoles reappeared and became normal in frequency and intensity. Conclusion: Ca can be partly, but not completely, substituted by Mg. G. SCHWOCH

Desinsulinized pancreas extracts. O. DA RIN. *Rass. clin terap. sci. affini* **29**, 70–9(1930).—Three patients with hypertension and 2 patients with angina pectoris were treated with Gley and Kisthinios' desinsulinized pancreas exts. (*C. A.* **24**, 4856). Only a slight, transitory reduction in blood pressure was observed, which according to D. is explained by the presence of peptone in the ext. The mechanism of the fall in blood pressure is similar to that obtained with exts. from other organs. The beneficial action which the prepn. had in some cases is probably due to the presence of min. quantities of insulin or to the stimulation of the pancreas induced by the ext D. holds that insulin acts on the blood pressure by means of a mechanism different from that of the desinsulinized pancreas exts. A bibliography is given. G. SCHWOCH

The treatment of the anemias with bone marrow extracts. GIACOMO PARENTI AND DARIO BARBIERI. *Rass. clin. terap. sci. affini* **29**, 192–208(1930).— Rabbits were made anemic by subcutaneous injections daily of 1–2 cc. of a 0.5% soln. of $PhNHNH_2$.HCl for 10 days. Part of these rabbits were then injected with a glycerol ext. of bone marrow; the other part was left untreated After 10 days the red blood cells and the hemoglobin had reached normal or almost normal values in the treated rabbits; also the leucocyte formula had become more or less normal. Only a slight improvement with regard to these factors was observed in the untreated animals. Rabbits injected simultaneously with $PhNHNH_2$.HCl and the ext. developed less serious symptoms of anemia or none at all. Seven cases of anemia are reported in which the administration of the ext. by mouth or by subcutaneous injection produced a distinct improvement in the subjective condition and in the blood picture of the patients. G. SCHWOCH

Claude Bernard's theory of narcosis. WILDER D. BANCROFT AND GEORGE H. RICHTER. *Proc. Natl. Acad. Sci.* **16**, 573–7(1930).—The theory that anesthesia is due to reversible coagulation of the proteins of the sensory nerves is thought to be supported by the fact that strychnine, $HgCl_2$, and HCN produce, when in high diln., increased irritability instead of narcosis, thus intermediate stage occurring as the proteins approach the point of instability. In confirmation of the reversibility, yeast cells coagulated by 2% Am ale. were brought back to normal transparency on removal of the ale. K. V. T.

Action of cinchona alkaloids in malaria. T. A. HENRY. *Chemistry & Industry* **49**, 786(1930).—Results of preliminary work indicate that quinine and quinidine are more efficient than cinchonine in treating bird malaria. The value of cinchonidine, however, is still uncertain Of the derivs. of quinine tried, the most promising is hydroquinine which in these preliminary tests gave better results than any other drug examd. On oxidation, quinine is converted into an acid, quitenine, which is inactive in malaria, but it is now shown that activity is regained when the acid is esterified and that, in a series of such esters, activity is slowly increased as the series is ascended, the Bu and Am esters being curative instead of merely retarding the development of the malarial parasite. Alstonia alkaloids have shown some activity in bird malaria, while akuamma and greenheart bark have shown none. R. P. WALTON

Mechanism of the action of arsenicals. HAROLD KING. *Chemistry & Industry* **49**, 786–7(1930).— K. considers that thiol groups in the body, such as cysteine, react with arsenoxides forming thioarsinites, the reaction being: $R.AsO + 2HS.R' \rightleftharpoons R.As(SR')_2 + H_2O$. K. and Gough have shown that such thioarsinites are slowly hydrolyzed by water to regenerate the original oxide and thiol compd. The thioarsinites are thus believed to constitute a tissue depot for gradual liberation of the oxide which is toxic to trypanosomes. **Reply.** H. J. BARBER. *Ibid* 802.—Because of the rapidity of the action of thioarsinites on trypanosomes, B. considers that the mechanism is not a slow hydrolysis to the oxide as suggested by King, but that the more probable mechanism is the surface adsorption of the thioarsinite followed by its preferential absorption of O. R. P. WALTON

1,3,4-Triazoles (BHAGAT, RAY) **10.** Derivatives of 4-methyl-, 4,6-, 4,7- and 4,8-dimethyl-2-hydroxyquinolines (BALABAN) **10.**

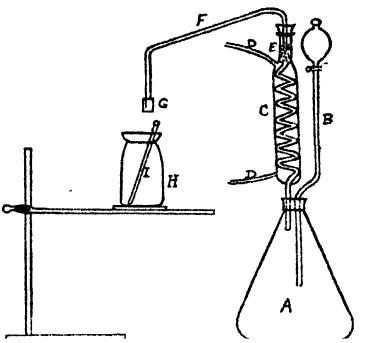
F. C. BLANCK AND H. A LEPPER

Wyatt William Randall (1867-1930). F. C. BLANCK. *J. Assoc. Official Agr. Chem.* 13, No. 4, ii–iv(Nov. 15, 1930).—An obituary with portrait.

A. PAPINEAU-COUTURE



Report on (the analysis of) coloring matters (used) in foods. C. F. JABLONSKI. *J. Assoc. Official Agr. Chem.* 13, 412–6(1930); cf. *C. A.* 24, 431.—The results obtained in collaborative work on the previously described method for the sepn. and *detn. of amaranth and tartrazine* were by no means accurate, but indicated that with more experience with the technic better results may be expected. Results obtained to date on the sepn. and *detn. of fast green FCF* from other coal tar dyes permitted in foods are briefly described. The sepn. of guinea green B from fast green FCF and light green SF yellowish is based on the facts that: (1) all 3 dyes are sol. in α-dichlorohydrin; (2) fast green FCF and light green SF yellowish are not extd. to any great extent by AmOH even from *N* HCl soln., while guinea green B is almost completely extd. by AmOH from a 5% NaCl soln. or from a weak acid (*N*/16 HCl). Sepn. of fast green FCF from light green SF yellowish is based on the fact the former reacts with Br with the formation of a blue soln., while the latter, under similar treatment, is destroyed. The following technic was followed: to 25 cc. of 1% fast green FCF in a 250-cc. beaker add H_2O to 70 cc., acidify with 4 cc. concd. HCl, heat to boiling, gradually add 25 cc. of 0.1 *N* bromide-bromate soln. with vigorous stirring, boil 5 min., evap. the soln. on a steam bath to about 1/4 the original vol., add 5 cc. concd. NH_4OH (to prevent carbonization), evap. to dryness and transfer with H_2O to a 250-cc. volumetric flask The following changes occurred during these operations: addn. of HCl produced a greenish soln., which was changed by the bromide-bromate at first to a brownish yellow and later to a deep blue, while NH_4OH made a purplish soln. The soly. of the resulting color soln. in AmOH was materially altered, as it was almost completely extd. from *N*/16 HCl. Wool dyed from a slightly acid soln. of the dye, with a deep blue-black shade which was stripped and redyed with a reddish black. *Spot reactions of the dyed wool:* concd. HCl, light green; concd. H_2SO_4, brown; 10% NaOH, reddish brown, concd NH_4OH, violet-blue. *Reaction of the aq. soln.:* Addn. of a small quantity of H_2O, blue-black; addn. of a large amt. of H_2O, reddish blue; HCl to aq. soln., greenish blue; AcOH to aq. soln., blue; strong NH_4OH to aq. soln., bluish red; 10% NaOH to aq. soln., orange-brown. A soln. of 25 cc. of 1% light green SF yellowish, treated similarly, produced a brownish yellow coloration. Expts. carried out by this method on mixts. in known proportions of the 2 dyes indicated that 4% of fast green FCF can readily be detected in mixts. with light green SF yellowish, while quantities as low as 0.4% of fast green FCF can be detd. only after extg. with AmOH, removing the decompn. products, dilg. with petr. ether, and extg. the color by means of dil. NH_4OH. Efforts to estimate the color by means of standard $TiCl_3$ were not entirely successful.

A. PAPINEAU-COUTURE

Report on (the determination of) preservatives (in foods). WYATT W. RANDALL. *J. Assoc. Official Agr. Chem.* 13, 409–12(1930).—From a discussion of Monier-Williams method for the *detn. of SO_2 in foods* and of Fitelson's work on the comparison of this method with the official A. O. A. C. method, it is recommended that the Monier-Williams method be adopted as tentative method and that it be studied collaboratively with a view to its substitution for the present official method. A. PAPINEAU-COUTURE

Report on (the determination of) arsenic in foods. W. C. TABER. *J. Assoc Official Agr. Chem.* 13, 417–22(1930).—A method is required suitable for the detn. of 0.2–10 mg. As, intermediate between the amts. determinable by the Gutzeit and the standard insecticide methods. The method suggested by Smith (*C. A.* 6, 3381) is based on the fact that when AsH_3 is passed into a $HgCl_2$ soln., there may be formed arsenides and other As and Hg compds. that are titrated with an I soln.; the reaction with I is essentially a titration from AsH_3 to As_2O_5 according to the equation: $2AsH_3 + 16I + 5H_2O = As_2O_5 + 16HI$. The method is particularly suitable for the detn. of As-spray residues on fruit, and may be applied in the field by working directly on the soln. obtained by washing 1–2 lb. of fruit with 300–500 cc. of 3% HCl or 3% NaOH. The following technic was developed: If the NaOH wash is used, neutralize and add 10–20 cc. concd. HCl in excess; place the acid or acidified wash in *A* (750-cc. capacity), add 10 cc. of reducing agent (KI, H_2O, concd. HCl and $SnCl_2$), heat to boiling, cool to about 80°, connect the app. as shown in the figure placing in *H* 10 cc. of 5% $HgCl_2$ dild. to 100 cc., loosen the stopper of *A*, quickly pour in 25 g. of granulated

30-mesh Zn, insert the stopper at once, make sure the app is tight (because of the highly poisonous nature of AsH_3); the reaction should start vigorously within a few min., add further amts. of the HCl soln. of reducing agent through *B* at such a rate as to ensure a lively reaction and a fast evolution of *H*, let the reaction continue for about 1 hr. or until the Zn is all used; disconnect at *G*, to the contents of *H* add 10 cc. of 15% KI to form the sol. $KI.HgI_2$, add an excess of about 25% of standard I (the requisite excess is judged by the color developed by the I); run in a standard As soln. to slight excess, using starch indicator, add 1 g. $NaHCO_3$, and titrate back with standard I. The difference between the total vol. of I and As solns. used × the As equiv. of the I = amt. of As. The As_2O_3 equiv. of the I soln. when titrating AsH_3 to As_2O_5 is 1/4 that when titrating As_2O_3 to As_2O_5; approx. 0.01 *N* is suitable. Good results were always obtained when using pure solns., but with fruit washes the recovery varied from 86.8–106.5%, due doubtless to the org. matter present. Comparison of the method with the Gutzeit method on sprayed fruit gave fairly good agreement, but the Gutzeit was somewhat lower, particularly with high As contents. The proposed method may be used successfully when applied to the acid digestion of various food products. It is being studied further with a view to overcoming interference of org. matter.

Arsenic Apparatus

A—Distillation flask, 750-cc. capacity.
B—Tube and separatory funnel for admitting acid.
C—Worm condenser
D—Tube for condensing water.
E—Cotton impregnated with lead acetate
F—Tube for conveying gas into mercuric chloride solution
G—Rubber connection for the tube I in H.
H—Half-pint milk bottle for mercuric chloride solution

A PAPINEAU-COUTURE

Report on (the determination of) copper (in foods). REED WALKER. *J. Assoc. Official Agr. Chem.* **13**, 426–7(1930).—The present tentative A. O. A. C method was found to be unsatisfactory because: (1) the wet digestion used in destroying org. matter is trustworthy but tedious; (2) the pptn. of the Cu with H_2S is tedious and of doubtful value for such small quantities of Cu; (3) digestion of the CuS ppt. and filter paper with HNO_3 and H_2SO_4 leads to high results. As a substitute for wet digestion, ashing in an elec. muffle proved satisfactory. Pptn. of Cu with satd $Na_2S_2O_3$ instead of H_2S and ignition of the CuS instead of digestion in HNO_3 and H_2SO_4 gave promising results, the most satisfactory procedure being as follows: Neutralize the soln. (obtained either by wet digestion or by dissolving the ashed sample in HCl) with NH_3, add 5 cc. concd. H_2SO_4, dil. to 200 cc., boil 1 min., cautiously add 10 cc. of satd. $Na_2S_2O_3$, boil until the ppt. coagulates and the liquid is practically clear, filter, wash with hot H_2O, ignite the ppt. in an elec. muffle at dull red heat, dissolve in 1 cc. HNO_3 (d. 1.12), transfer to a 100-cc. Erlenmeyer flask, evap. to dryness on a steam bath, dissolve in 20 cc. H_2O, add excess NH_4, boil till the soln. turns light brown, add a slight excess of AcOH, boil 1 min., cool to room temp., add 2 g. KI dissolved in enough H_2O to make the final soln. 50 cc. (including the standard $Na_2S_2O_3$ used in titrating), titrate with 0.01 *N* $Na_2S_2O_3$, adding 2 cc. of freshly prepd. 1% starch soln. near the end of the titration.

A. PAPINEAU-COUTURE

Report on (the determination of) boron (in foods). O. F. KRUMBOLTZ. *J. Assoc. Official Agr. Chem.* **13**, 422–3(1930).—The present official A. O. A. C. method for the detn. of boric acid in fertilizers gave recoveries of 95–7%. The MeOH recovered for use in subsequent detns. was found to have carried off about 5% of the H_3BO_3. This error is considerably reduced by using a large excess of alkali; but too much alkali dissolves a little of the H_3BO_3 from the glass. A method based on the use of superheated steam, as originally suggested by P. Chiyevskii (*Arch. sciences Genève* [3], **12**, 146(1884)) has been developed; superheated steam is obtained by passing steam from an outside source through a coiled tube in an electrically heated Cu cylinder contg. vapors from a boiling kerosene fraction sufficient to heat the steam to 180–90°; through the top of the cylinder is set a large test tube contg. the H_3BO_3 to be distd. The method gave recoveries of 99.5–100.2% of pure H_3BO_3 or acidulated borax. When org. matter is present, the sample must first be rendered alk., ashed at low red heat, and then acidified

and distd. Some of the simpler mixts., *e. g.*, dextrose and H_3BO_3, gave recoveries of 99.0-99.7%; with wheat flour a loss of several % of H_3BO_3 was noted, indicating a greater retention of B by the ash. The method is being studied further. A. P.-C.

Report on (the determination of) tin (in foods). U. Liddel. *J. Assoc. Official Agr. Chem.* **13**, 423-5(1930).—Present methods of detg. Sn in foods are briefly reviewed critically, and the drawbacks of the present tentative A. O. A. C. methods are outlined. The following method has given satisfactory results after the Sn was in soln. and org. matter removed: Adjust the vol. of the soln. to 100 cc. by evapn or diln., add 57 cc. concd. HCl to make the acidity of the soln. 4 *N*, add 2 drops of 1% $SbCl_3$ and then approx. 0.2 g. reduced Fe powder, boil till the Fe is completely dissolved (keeping the flask covered with a funnel), add a small piece of marble, cool quickly in ice to about 20°, add an excess of standard I soln., and immediately titrate the excess I with 0.2 *N* $Na_2S_2O_3$. Bibliography of 22 references. A. Papineau-Couture

Fermentations in the food industries. F. C. Blanck. *Ind. Eng. Chem.* **22**, 1166-8(1930).—A survey is given of the fermentation processes involved in the prepn of various foods such as bread, tea, coffee, cocoa, sauerkraut, pickles, vinegar, sauces, olives, cheese, etc. The value of these food products and the relation of the chemist and micro-biologist to the problems of production are briefly mentioned. C. N. F.

Report on (the analysis of) cereal products. J. A. LeClerc. *J. Assoc. Official Agr. Chem.* **13**, 433-8(1930); cf. *C. A.* **24**, 432. A brief review of the progress accomplished by the Assoc. in 1928-9 on the analysis of cereal products, and discussion of the reports of the associate referees (see following abstracts). A. P.-C.

Report on sampling of flour. H. Runkel. *J. Assoc. Official Agr. Chem.* **13**, 439 (1930); cf. *C. A.* **23**, 212.—It is recommended that the official A. O. A. C. method for sampling flour be studied collaboratively with respect to other detns. than that of water, and that a "metal" (instead of "steel") trier be specified. A. Papineau-Couture

Report on gasoline color value and ash determination in flour. D. A. Coleman *J. Assoc. Official Agr. Chem.* **13**, 439-42(1930); cf. *C. A.* **23**, 213.—It was ascertained from prominent cereal chemists that the detn. of gasoline color in flour is rarely used in any practical way by any of the large mills (in the U. S.), in a crude way it is sometimes used by those interested in the sale of flour-bleaching equipment to demonstrate the efficiency of their products, and in a limited way by certain plant breeders to test approx. the carotene content of wheat and flour. Moreover, new and more precise methods for detg. color can be devised. The Walters method for the detn. of ash (*C. A.* **24**, 1676) was compared with the A. O. A. C. method and with this method modified by the use of glycerol-alc., on 4 straight-grade flours milled from hard red spring, hard red winter, soft red winter, and white wheat, resp. Temps. of 750°, 800° and 850° were used in the Walters method. With the hard wheat flours, fairly close comparisons were obtained by use of Walters method at 800-50° and the A. O. A. C. method with soft red winter wheat flour difficulty in ashing was experienced at all temps.; all the temps. used were too high for ashing the white wheat flour. On repeating the detns. with 3 g. of flour and 6 cc. of La soln., somewhat better results were obtained, but the necessity of using different ashing temps. for certain classes of flour was again apparent: hard red spring, hard red winter and soft red winter flours ashed in fairly good form at 800-50°, but comparable results in ashing the white wheat flour were obtained at temps. not in excess of 750°. The ashing crucibles were found to change wt. after each test in a manner that might seriously affect the results, but it was not detd. whether this was due to the high temp. of ashing or to a combustion of the elements of which the crucible was made with the La_2O_3 or the oxides in the flour ash. A. Papineau-Couture

Report on (the determination of) glutenin in flour. M. J. Blish. *J. Assoc. Official Agr. Chem.* **13**, 442-3(1930); cf. *C. A.* **24**, 432.—A brief outline of the results recently obtained by B. and Sandstedt concerning the nature of glutenin (*C. A.* **24**, 897). A. Papineau-Couture

Report on (the determination of) flour-bleaching chemicals. G. C. Spencer *J. Assoc. Official Agr. Chem.* **13**, 447-9(1930); cf. *C. A.* **24**, 433.—Two samples of commercially bleached flour, one by the "Beta-Chlora" and the other by the "Agene" process, were analyzed collaboratively by the Seidenberg method (*C. A.* **22**, 1197). The "Beta-Chlora" bleached flour yielded 227-284 p. p. m. of Cl (av. 263 p. p. m.), and the "Agene" flour 0.0-11.9 p. p. m. (av. 5.0). Analysis by the same method of 6 samples of unbleached flour showed 0.0-24.9 p. p. m. of Cl. Adoption of the method as tentative is recommended. A. Papineau-Couture

Report on foreign methods for testing flour. C. H. Bailey. *J. Assoc. Official Agr. Chem.* **13**, 449-55(1930).—The A. O. A. C. and the Greek official methods for

detg. the acidity of flour differ in that the former exts. with H_2O and expresses as lactic acid, while the latter exts. with 85% alc. and expresses as H_2SO_4. The ratio of the results obtained by the 2 methods varies considerably, the factors required to convert Greek acidity into A. O. A. C. acidity being as follows: 0.05% by Greek method, factor 6.0; 0.10%, 4.2; 0.15%, 3.3; 0.20%, 2.4. Despite these complications, the results obtained by either method serve as a reasonably adequate basis for estg. the probable percentage as detd. by the other method. A brief survey is made of past activities of the A. O. A. C. in connection with the detn. of acidity in flour, and it is recommended that the collaborative study of this detn. be reopened with a view to (*a*) ascertaining the fundamental sources of variability in the application of the tentative A. O. A. C. method, and (*b*) comparing these results with those obtained by alc. extn. such as used in the present Greek method. A. PAPINEAU-COUTURE

Report on sampling and determination of moisture in bread. L. H. BAILEY. *J. Assoc. Official Agr. Chem.* **13**, 455-7(1930); cf. *C. A.* **24**, 433.—Previous observations on the lack of uniformity of distribution of moisture in a loaf of bread were confirmed, and it is therefore recommended that an entire loaf of bread be taken as a sample for the detn. of moisture. A. PAPINEAU-COUTURE

Report on hydrogen-ion determinations (in flour). C. H. BAILEY. *J. Assoc. Official Agr. Chem.* **13**, 444-5(1930), cf. *C. A.* **23**, 213. A collaborative comparison of the use of the quinhydrone electrode and the H electrode in the electrometric detn. of the p_H value of flour by the A. O. A. C. tentative method showed that the variability was about the same by the 2 methods. It is concluded that the quinhydrone electrode is suitable for this detn.; but it should be noted that the sensitivity of the potentiometer set-up is diminished when the ordinary quinhydrone electrode is substituted for the usual types of H electrodes. A. PAPINEAU-COUTURE

Report on (the determination of the) diastatic value of flour. ARNOLD H. JOHNSON. *J. Assoc. Official Agr. Chem.* **13**, 445-6(1930), cf. Tague, *C. A.* **24**, 433.—It is shown that the diastatic activity of flour increases with the degree of fineness to which it is ground and also that extn. of a flour with Et_2O gives a flour of higher activity than the unextd. flour; as the extd. flour appears much finer than the unextd. flour, the apparent increase in activity might be attributed to increased susceptibility of the substrate to diastasis. It was thought that by extg. flours with Et_2O all flours would become of the same particle size, hence would provide a uniform substrate, and differences in sugar-producing power would be due entirely to differences in diastatic activity and not to differences in susceptibility of substrate to diastasis. Two flours milled from the same wheat, but ground so that one had about twice the diastatic activity of the other, were extd. with Et_2O with the hope that the 2 flours would then have the same diastatic activity; both flours, however, increased in diastatic activity in about the same ratio. It was found that the optimum H-ion concn. for diastatic activity varies with different flours, and that the differences are not due to the different electrolyte contents of the flours. A. PAPINEAU-COUTURE

Report on (the determination of) crude fiber in alimentary pastes and in air-dried baked cereal products. W. F. STERLING. *J. Assoc. Official Agr. Chem.* **13**, 457 (1930).—The technic of the official A. O. A. C. method for detg. crude fiber in flour was found to be entirely satisfactory for detg. crude fiber in air-dried baked cereals and in alimentary pastes and its adoption as official for these materials is recommended. A. PAPINEAU-COUTURE

Report on experimental baking tests. M. J. BLISH. *J. Assoc. Official Agr. Chem.* **13**, 458-66(1930); cf. *C. A.* **24**, 433.—Following Harrel's investigation (*C. A.* **24**, 1749), B. undertook a series of tests with 6 experienced collaborators, the results of which are given in detail. There was fairly satisfactory agreement as to the nature of the differential between loaves baked with and without the addn. of 1 mg. of $KBrO_3$, to the extent that nearly all treated loaves showed a decrease in vol., any lack of agreement in this connection being more in degree than in kind. As was to be expected from the fact that there were fewer collaborators and they were presumed to have had extensive experience in the use of the method, there was far more encouraging concordance of results in the present series than in Harrel's. It is expected that ultimately all factors, with the possible exceptions of yeast and atm. pressure, will be under satisfactory and uniform lab. control. The factors of mixing, molding, ovens and yeast are probably the more prominent contributors to the difficulties that are being encountered under present circumstances. Continuation of the coöperative work on this problem with the Am. Assoc. of Cereal Chemists is recommended. A. P.-C.

Report on (the determination of) water-soluble protein, unsaponifiable matter, ash and total solids in flour and alimentary pastes. SAMUEL ALFEND. *J. Assoc.*

Official Agr. Chem. **13**, 467–9(1930); cf. *C. A.* **24**, 434.—It is recommended that the tentative acid-hydrolysis method for fat and the tentative methods for lipoids and lipoid P_2O_5 in alimentary pastes be definitely adopted as official Collaborative study during 3 yrs of the tentative F. A. C. method for the detn. of unsapon. matter in the fat of alimentary pastes, baked cereal products and flour has given results lacking in uniformity, and the method should be studied to det what factors are causing irregularities in the results. The effect of NaCl in the detn. of alc.-precipitable N in flour and alimentary pastes was investigated. Adding the alc. before the NaCl sometimes gave higher results and sometimes had no effect on the results; when NaCl was omitted entirely, the ppt. formed more slowly, but it gave as high results if allowed to coagulate overnight, as when NaCl was used, while in some cases the results were distinctly higher when NaCl was omitted. The rise in temp. caused by the addn. of alc apparently had no influence on the formation of the ppt. Good check results are difficult to obtain, because of difficulty in packing the ppt. on centrifuging, and also because of the frequent formation of a colloidal soln. which passes through the filter pad; and A. concludes that the present method is not reliable for all samples. Use of 1.2% NaCl soln. for extn. of the proteins from the sample is a decided improvement, but work along this line was discontinued because this method yields higher results, and all the authentic data available are based on water-sol. N The use of asbestos or of $CaCO_3$ for improving the packing of the alc. ppt. on centrifuging and the subsequent filtration is practically useless; Al_2O_3 cream gives an excellent pack from which the clear liquid can be poured off readily, but its use gives much higher results. The logical step is to add Al_2O_3 cream to the aq. ext. just before filtration, which gives a somewhat clearer soln. for flour or noodles, but with powd. whole egg and liquid egg it changes a muddy filtrate into a sparkling clear soln The difference between the quantities of alc.-precipitable N in the solns. before and after clarification is striking (no figures are given), the results for the clarified solns. being lower than the usual values, particularly with egg samples. A. PAPINEAU-COUTURE

The sterilization of flour and of enzymes in powdered form. III. J. J. VAN DE VELDE. *Bull. sci. acad. roy. Belg.* [5], **16**, 585–91(1930); cf. *C. A.* **14**, 3112.—For sterilization the powd materials were placed in sterile Petri dishes and covered with pure, freshly distd. CS_2. The dishes were placed in a large metal oven, kept at atm temp., and the CS_2 was allowed to evap. spontaneously. The crusts of material formed during evapn. of the CS_2 were loosened from the dish and pulverized with a sterile spatula. The dishes with their contents were then placed in a glass desiccator, through which a current of air, dried and sterilized by passage through concd. H_2SO_4, was led to remove all traces of CS_2. All odor of CS_2 was gone after one day. Tests made upon amylase after this treatment showed that (1) its hydrolyzing properties had not been affected; (2) it was sterile; and (3) it was susceptible to easy infection, *e. g.*, with *B. fluorescens liquefaciens*. After treatment with CS_2, pepsinase was found to have somewhat more active enzymic properties than before; it was sterile, but easily reinfected. LOUISE KELLEY

Standardization of milk with skim milk powder for the manufacture of Cheddar cheese. H. C. HANSEN AND D. R. THEOPHILUS. *Concentrated Milk Industries* **1**, No. 1, 44–6(1930).—Milk was standardized to fat : solids-not-fat ratios of 1 : 2.6, 1 : 2.8 and 1 : 3.0 with spray-dried skim milk and successfully manufactured into Cheddar cheese. The 1:3.0 ratio often gave a H_2O content above and a fat content below the legal limit F. L. SEYMOUR-JONES

Importance of the solubility of milk powders. J. C. MARQUARDT. *Concentrated Milk Industries* **1**, No. 1, 41–2(1930).—The age of ice cream and cream cheese was found to affect their quality more than the age or soly. of skim milk powder used in their manuf. Powder soly. had no effect on cream cheese quality When highly insol powders are used, ice cream texture is improved by high pasteurization temps F. L. SEYMOUR-JONES

Sweet cream—some practices to guard against. H. H. SOMMER. *Concentrated Milk Industries* **1**, No. 2, 16–7(1930).—An av. of 15 samples showed for per cent cream acidity by different methods (*A*) 9-cc. pipet, not rinsed, 0.096; (*B*) 9-cc. pipet, rinsed with 9-cc. H_2O, 0.085; (*C*) 9-g. cream, 0.107; (*D*) calcd. from acidity of skim and the per cent fat in cream 0.811. In neutralizing cream with $NaHCO_3$ it is necessary to boil off CO_2 to obtain a true titration. F. L. SEYMOUR-JONES

Sweet cream. The prevention of cream plugs. H. H. SOMMER. *Concentrated Milk Industries* **1**, No 3, 11–2, 23(1930).—Cream plugs contg. 65–70% fat are due to rise of fat globules and not to surface evapn. Their formation depends on serum viscosity and size of fat globules. Coalescence or clumping of globules, particularly

by agitation of the milk or cream between 50° and 95°, favors plug formation. The addn. of citrates decreases the tendency to form plugs, presumably by increasing the charge on, and hence the electrostatic repulsion between the fat globules. Low-pressure homogenizing (200-1000 lb.) can be used as a remedy for plugs. F. L. S.-J.

Variation in the analytical indices of butter caused by changes due to aging. F. Arnaudo and A. Soldi *Ann. chim. applicata* **20**, 405-9(1930).—Analyses of 20 samples of butter kept for periods up to 14 months show that the Zeiss index of refraction drops from 0 2 to 2.2 units; the Reichert-Meissl no. 0.4 to 7.2 units; while the total free acids may increase by amts. corresponding to over 100 cc. *N* alkali /100 cc. A. W. Contieri

Report on (the analysis of) eggs and egg products. Samuel Alfend. *J. Assoc. Official Agr. Chem.* **13**, 405-9(1930); cf. *C. A.* **24**, 437.—Further collaborative work on the *detn. of ash* on liquid whole egg, liquid yolk and powd. dried whole egg gave results which were somewhat better than those obtained the previous year and which, considering the nature of the product and the difficulty of ashing, are considered quite satisfactory, though there was a max. variation of 0.24% in the results on powd. dried egg. The method for the *detn. of H_2O-sol. protein precipitable by 40% alc.* cannot be relied upon to give concordant results on the same sample at different times or to yield the same kind of ppt. and of soln. on 2 samples run side by side. One source of error is the frequent presence in the aq. soln. of a very fine suspension which comes through the filter and is frequently carried down in the subsequent alc. pptn., causing high results; another is the failure of the ppt. to coagulate, leading to loss of N by passage of the fine ppt or colloidal suspension through the filter pad. Alumina cream carries down the ppt completely in a short time, leaving a clear soln. which can be poured off without the necessity of filtering it through asbestos The results are considerably higher when Al_2O_3 cream is used, which is due partly to better packing of the ppt., partly (in some cases at least) to the carrying down of finely suspended material which otherwise comes through the filter mat in the aq. extn., and possibly also to adsorption by the Al_2O_3 cream of alc.-sol. protein which the subsequent washing fails to remove Egg exts. pptd in the absence of NaCl give distinctly lower results, and in some cases even fail to give any ppt. With flour and noodles, on the other hand, pptn. in the absence of NaCl gives results as high as or higher than those obtained by pptn. from a 1 2% NaCl soln. Practically the same results are obtained whether the NaCl is added before or after the addn of alc It is necessary to allow 12-18 hrs. for coagulation of the ppt. in the presence of NaCl, and longer when no NaCl is added. Further collaborative work on the *detn. of total solids in eggs*, in which all collaborators worked on the same samples, showed that close agreement is obtainable by different analysts by the vacuum oven method (drying at 98°) on liquid whole egg, liquid egg yolk and powd dried whole egg Results by the rapid air-oven method (drying 3 hrs. at 112-7°) showed a greater variation, but the av. values checked closely with those by the vacuum oven method, except with powd dried egg, with which air-drying yielded uniformly high results. A. Papineau-Couture

Report on (the analysis of) meat and meat products. R. H. Kerr. *J. Assoc. Official Agr Chem.* **13**, 478(1930); cf. *C. A* **24**, 438.—Preliminary expts. have indicated that, if proper precautions are taken, total water in meats and meat products can be detd. by drying at 125° with an accuracy comparable with that of the official A. O. A. C method, and within a time period of 2-3 hrs. The method will be studied collaboratively. A. Papineau-Couture

The determination of purines in meat extracts. Adolfo Escudero and Gregorio Waisman *Semana méd.* (Buenos Aires) 1930, II, 1436-8.—A 10% soln of the ext. is treated by the method of Folin and Wu, to remove the proteins. The purines are detd by the method of Krueger-Smid with $CuSO_4$ and $NaHSO_3$ for pptn. A. E. M.

Report on (the analysis of) fruit products. H. J. Wichmann. *J. Assoc. Official Agr Chem.* **13**, 427-31(1930).—In an effort to make them more exact, the previously reported methods for the *analysis of fruit ash* (cf. Tilden *C. A.* **22**, 122; **23**, 217; **24**, 438) were altered somewhat by conducting the pptns. at approx. p_H values detd. by color changes with bromocresol green, the results in the main being satisfactory. In studying the inversion which occurs in the drying method of detg. total solids in sweetened fruit juices, Kathryn Bryn confirmed that an asbestos or sand absorbent reduces the amt of inversion in the drying of a soln. of sucrose and tartaric acid, thus giving closer agreement with the actual % of solids and solids detd. by refractive methods. This is true regardless of the materia of the drying dishes; the smaller amt. of inversion in presence of an absorbent is therefore apparently due to the greater sepn. of the mols of sugar and acid and not to the catalytic action of the material of the dish. The

inverting action of citric acid (which is a weaker acid than tartaric acid) will be studied next; and it was found that citric acid loses all its H_2O of crystn. *in vacuo* at 70°. In view of the results obtained by Myers and Baker (*C. A* **24**, 4340), the effect of a definite p_H and curtailment of time of boiling in the alc. ppt., pectic acid and ash percentages should be studied for a variety of fruits and not only in citrus albedos; the possible effect of sugar on the extn. of pectin should also be studied. A. P.-C.

The extraction of pectin from lemon pulp. P. Leone. *Ann. chim. applicata* **20**, 433-44(1930).—Pectin is extd. from the pulp with 5% HCl, which at the same time hydrolyzes the sugars present which may then be fermented. Pectin is repptd. with 95% EtOH, this EtOH being recovered later. The EtOH obtained from the fermentation serves to replace that lost in the process, thus making the process practical commercially. A. W. Contieri

Heat transfer of foods during freezing and subsequent thawing. I. Temperature changes in sugar solutions, sweetened fruit juices and other liquids. M. A. Joslyn and G. L. Marsh *Ind. Eng. Chem* **22**, 1192-7(1930).—Detns. were made of the rate of temp. change of H_2O, sugar solns., pectin solns., and fruit juices in No 10 tin cans, during freezing at −17.8° and thawing at 21.1°. The rate of change varied with the sp. heat of the soln., the heat cond., the f. p., and the amt. of ice that formed. Heat transfer depended chiefly on conduction. With increasing sugar concn. the initial rate of cooling was increased, the f. p. was lowered, the period of const. temp was shortened and the rate of cooling of the frozen product was decreased. Viscosity had no appreciable effect. Amy LeVesconte

Report on (the analysis of) flavors and non-alcoholic beverages. J. W. Sale. *J. Assoc. Official Agr. Chem.* **13**, 475-7(1930); cf. *C. A.* **24**, 440.—Collaborative work on the Parker and Hiltner method (*C. A.* **12**, 1908) for the colorimetric *detn. of citral* in oils and exts. gave results which agreed well with one another, and also with those obtained the previous yr. on the same samples. Adoption of this method as official is recommended. The Radcliffe and Swan method (*C. A.* **22**, 1747) for the *detn. of total aldehydes* was compared collaboratively with the Kleber method; and it was found that in its present form (described in detail) it gives appreciably higher results than the Kleber method. Further collaborative work should be done before it can be adopted but S. considers that it is possible to make certain modifications to improve it. A. Papineau-Couture

Diastatic activity of honey. L. H. Lampitt, F. B. Hughes and H. S. Rooke. *Analyst* **55**, 666-72(1930).—To obtain further information concerning the general characteristics of the amylases present in honey, the effect of varying conditions of acidity on the activity of the dextrinogen-amylase and of the saccharogen amylase, the effect of change in temp. on these at the optimum p_H, the effect of time of reaction in the detn. of the saccharogen-amylase and the stability of these amylases were studied. As a result of considerable experimentation, the following conclusions were drawn: Honey diastase behaves like other enzymes under varying conditions of temp and p_H, the optimum p_H being 4.7-5.3. The max. dextrinogenic power is obtained at 38-45° and at 10-60° the optimum p_H is the same whatever the temp. may be. The amt of reducing sugars produced by the saccharogen-amylase increases with the time but after 16 hrs. the rate of increase is very slow. The optimum p_H for the saccharogen amylase is also about 5.3. Below p_H = 4.0 or above p_H = 9.0, both of the enzymes are destroyed but at p_H = 4-6 the dextrinogenic activity appears to be stable. On account of the variation in the diastatic activity of honey, measurements of this activity cannot be relied upon to detect adulteration or the heating of honey. W. T. H.

Determination of fat in chocolate. C. E. Wiseman. *Analyst.* **55**, 684-5(1930). The Gottlieb method for detg. fat in sweetened condensed milk can be adapted to the analysis of chocolate by immersing the aq. NH_3 suspension of the chocolate in boiling water for 5 min. Later, somewhat more alc. than usual is necessary and the extn. flask must be weighed after the removal of most of the fat. W. T. H.

A chocolate adulterated in an exceptional manner. Giovanni Issoglio *Giorn. farm. chim.* **79**, 314-6(1930).—The analysis of a sample of adulterated chocolate gave the following result: H_2O 27.00, ashes 1.14, fat 10.22, total carbohydrates 58.00 and extractive substances 5.00%. The fat was partly composed of coconut butter. The chocolate reacted alk. to indicator paper, because of the presence of an admixt. of Na_2CO_3, which was apparently added to prevent the breaking-up of the cacao-water emulsion. Part of the sol. carbohydrates consisted of technical glucose. The chocolate contained a considerable quantity of salicylic acid G. Schwoch

The influence of clover silage on the milk production of dairy cattle. E. Ya. Borisenko. Trudui Vologod. Molochno-Khozyaistv. Inst., *Bull.* No. **81**, 71-103

(1929).—The chem. analyses of the feed, the daily rations, the milk records, temp. records, milk fat analyses and solids are given in series of tables. From the data thus obtained the correlation coeff. for a daily milking was calcd. for the feed given with and without the silage. An analysis of the data shows that silage feeding increases the production of milk. It has but very little effect on the percent of fat in the milk. No change in the total N of the urine or the milk was found with or without silage feeding. J. S. JOFFE

Organization of the international union for furthering production and utilization of drug, spice and related plants (HIMMELBAUR) **17.** Emulsions and suspensions of various kinds (Brit. pat. 332,533) **13.** Electrically heated apparatus for roasting coffee, cocoa, etc. (U. S. pat. 1,782,946) **4.** Apparatus for freezing ice cream, egg yolks and whites, etc. (U. S. pat. 1,783,864 5-6-7) **1.** Purifying yeast after use for fermentation (U. S. pat. 1,783,521) **16.** Apparatus for separating entrained liquid from vapors such as produced in concentrating juice or sirup (U. S. pat. 1,784,627) **1.**

Preserving foods. HERMANN ALEXANDER VERLOOP. Ger. 506,227, Oct 9, 1928. The vessel contg. the food is evacuated as far as possible, and the residual O is converted into ozone. App. is shown.

Milling flour. LOUIS E. SMITH (to Hart-Carter Co.). U. S. 1,784,762, Dec. 9. The whole grain is subjected to a crushing compression to crack the bran and break down the endosperm (some of the endosperm being pressed into the form of flakes), the middlings portion of the resulting stock is subjected to a multiplicity of non-uniform compressional impacts by which the endosperm and flakes from it are further reduced to, or toward, flour form without materially disintegrating the bran flakes, and the bran is sepd. from the flour Arrangement of app is described.

Treating milk. F. H. FAULDING & CO., LTD. Brit. 332,595, April 24, 1929. See Australia 19,016 (*C. A* **24**, 3576). Brit. 332,597 relates to similar compns. in granular form for addn to milk.

Thermostatic device suitable for control of milk pasteurizers. BYRON J PEPPER. U. S. 1,784,465, Dec. 9. Structural features.

Preserving milk by successive treatment with carbon dioxide, oxygen and nitrogen. I. HOFFS and A. REPPMAN. Brit. 332,641, April 26, 1929 App is described.

Preserving milk and milk products and mixtures. W. R. B. ST. J. GATES, J. LYONS & CO. AND COW & GATE, LTD. Brit. 332,669, May 14, 1929. A small proportion (suitably about 1.5%) of glycerol or other polyhydric alc. such as dimethylene and trimethylene glycol or propylene glycol is added to prevent development of rancidity in milk, dried milk, cream, butter, etc.

Preserving butter and margarine. AKT.-GES. FÜR MEDIZINISCHE PRODUKTE. Brit. 332,806, Sept. 9, 1929 See Ger. 502,290 (*C. A.* **24**, 4874).

Coloring material for oleomargarine, butter, etc. JACOB SCHAUB (to Best Foods, Inc.). U. S. 1,783,154, Nov. 25. A dry coloring material is prepd. by dissolving a dye in a volatile solvent carrier, absorbing the colored soln. by porous material such as starch and then evapd. the solvent.

Preserving egg yolk. C. H. BOEHRINGER SOHN (Alfred Häussler, inventor). Ger. 506,095, Mar. 24, 1929. Liquid egg yolk is treated with a preservative, *e. g.*, PhCOOH or its salts, and a buffer compd or mixt. such as will maintain the H-ion concn in the range p_H 4.5–7, *e. g.*, disodium citrate or a phosphate buffer mixt. An example is given. Cf. Ger. 494,363 (*C. A.* **24**, 2812).

Oven and associated apparatus for toasting and shredding materials such as cereal foods. JOHN L. KELLOGG (to Kellogg Co.). U. S. 1,783,434, Dec. 2 Structural features.

Food from unripe corn. HARRY A. ERYSIN and KRIKOR B CHICKERING. U. S. 1,782,960, Nov. 25. Ears of corn in the milk stage are roasted until the kernels are thoroughly dry, the roasted kernels are shelled from the cob and are ground into meal.

Apparatus for sterilizing figs or other dried fruits. JOHN G. TYLER, CHARLES C. TAYLOR and WM. S. JOHNSON (to Calif. Peach & Fig. Growers Association). U. S. 1,782,522, Nov. 25. A foraminous belt carries the material through a heat-insulated chamber supplied with hot air from an adjacent auxiliary compartment.

Apparatus for continuous roasting of coffee. ALBERT K. REHE (one-half to Reginald A Kucich). U. S. 1,783,673, Dec. 2. Structural features of an app. with elec. heaters.

Food for animals. HUGO REIK. Austrian 119,039, April 15, 1930. Food for

animals is mixed with a pure culture of microörganisms capable of breaking down the unassimilable constituents. Thus, a culture of cellulose-splitting bacteria may be added to fodder.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Science and modern industry. WM. J. POPE. *Chemistry & Industry* **49**, 966–70 (1930). E. H.

How to approach the problem of joint costs in chemical industry. THEODORE J KREPS. *Chem. Met. Eng.* **37**, 678–80(1930). E. H.

Chemical engineering memoranda. XII. Exchange of heat: heaters and coolers. CHARLES H. BUTCHER. *Ind. Chemist* **6**, 404–7(1930); cf. *C. A.* **24**, 5185.—This discussion includes: the principle on which the diam. of tubes in heat exchangers should be selected, duty of heat exchangers, types, tube proportions and spacing, disposition of liquids in the system and the methods of developing formulas and making the necessary calcns. for typical cases to det. prevailing temp. conditions, film coeffs. for transfer of heat, overall coeff. and mean temp. difference. E. G. R. ARDAGH

The physical characteristics of industrial powders. H. MARSHALL. *Can. Chem. Met.* **14**, 314–6(1930).—According to their mode of prepn., powders fall into the following classification: (1) ground igneous rocks or glasses and stamped metallic powders, (2) ground earths and rocks of softer types, (3) pptd. powders, (4) calcined powders and (5) sublimed powders and "fume" pigments. Points discussed include: wetting, the settling of powders from liquids, the theory of liquid films, emulsification of powders, adsorption phenomena, and the manuf. and packing of powders. A bibliography is appended. W. H BOYNTON

An analysis of mechanical methods of dust collection. MARCEL A. LISSMAN *Chem. Met. Eng.* **37**, 630–4(1930).—A math. analysis of the principles governing the particle movement. E. M. SYMMES

Bulking properties of microscopic particles. PAUL S ROLLER. *Ind. Eng. Chem.* **22**, 1206–8(1930).—Investigation of anhydrite, gypsum, portland cement and chrome yellow in fine powder form showed that bulkiness, or vol. per unit wt., increases with decrease in particle size below a crit. diam. For particles greater than the crit. diam. the bulkiness was const. It was found that the voids per g., V, is related to the diam. of the particle in the same functional way for all the powders examd. A rapid method has been devised for estg. mean particle size of microscopic powder from a knowledge of its curve of bulkiness *vs.* particle diam., providing suitable correction is made for powders above 1 micron surface mean diam. L. T. FAIRHALL

The removal of water during concentration. A. ALISON. *Ind. Chemist* **6**, 402–7 (1930).—In order to shorten the time required to calc. the amt. of H_2O to be removed in drying or concg. operations the use of a nomograph is recommended. An illustration and description of the nomograph are given and also its method of construction and an example illustrating its use. E. G. R. ARDAGH

Observations and notes on the effect of methanol antifreeze on health. R R SAYERS AND W. P. YANT. *Bur. Mines, Information Circ.* **6415**, 7 pp.(1930).—Practically continuous exposure to low concns. and short intermittent exposure to high concns. of methanol cause no apparent harm. Continuous exposure to high concns will cause serious poisoning. Methanol is poisonous when taken internally. ALDEN H. EMERY

Fatalities due to vitiated air produced by oxidation of vegetable refuse. ARNOLD R. TANKARD AND DOUGLAS J. T. BAGNALL. *Analyst* **55**, 673–6(1930).—The fact that vegetable substances, in the presence of air and moisture, may undergo a process of autoxidation in unventilated spaces, gradually producing a lethal mixt. of gases, was demonstrated by the death of 3 workmen in a deep manhole which received the sub-soil drainage from low-lying and water-logged, trenched land. Analysis of the sump air showed 88% N, 10.6% CO_2 and only 1.4% O by vol. The workmen collapsed immediately on reaching the bottom of the sump. W. T. H

C black in rubber insulating compounds (CURTIS, MCPHERSON) **30.**

Liquefying and separating constituents of air or other gas mixtures. KARL F R. MEWES. U. S. 1,781,693, Nov. 18. App. and various details of heat-transfer, etc., are described.

Recovery of volatile hydrocarbons. ANTON WEINDEL. Ger. 504,731, Feb. 4, 1927. The hydrocarbon vapor, mixed with a gas stream, is passed into the PhOH-contg. water obtained in the dry distn. of bituminous materials (*e. g.*, NH_3 water from coking and gas plant, etc.), at a high temp. The water is cooled, causing the hydrocarbons absorbed to sep. These are removed and the liquid is used again.

Breaking up natural petroleum emulsions or other colloid systems by use of rays of short wave length. ABRAHAM M. HERBSMAN. U. S. 1,783,471, Dec. 2. Emulsions, foams, smoke and other disperse systems are treated with rays such as those from a quartz Hg vapor lamp, x-rays, cathode rays, canal rays or rays from radioactive substances. App. is described suitable for treating petroleum emulsions to effect sepn.

Emulsions and suspensions of various kinds. P. FREEDMAN. Brit. 332,533. April 15, 1929. High-frequency vibrations produced by electrically excited piezoelec. crystals (which may be directly in contact with the ingredients or may be in an envelope filled with liquid to transmit the vibrations) are utilized in the prepn. of products such as *mayonnaise, aq. suspensions of S, dispersions of guncotton in AmOAc*, etc. Various details of the prepn. of mayonnaise are given.

Dispersions. AUGUST CHWALA. Ger. 504,598, May 22, 1928. Substances insol. or almost insol. in water, with the exception of phosphates or arsenates of alk. earth or heavy metals, are dispersed mechanically in water by using as peptizers alkali pyro or meta-phosphates or arsenates. In examples, substances such as titanium white, $CaCO_3$, lithophone, zinc white and kaolin are dispersed by using pyrophosphates or pyroarsenates as peptizers. Cf. *C. A.* **24**, 2560.

Pumping liquids against high pressure. I. G. FARBENIND. A.-G. (Albert Berenbruch, inventor). Ger. 506,240, May 9, 1929. A method and app. are described for recovering the energy imparted to the liquid. The pressure of the liquid is imparted, by means of a membrane or piston, to a second liquid, in such a manner that the latter counteracts the high pressure.

Coating and impregnating webs of flexible material such as fabric or paper. EMIL WEINHEIM. U. S. 1,784,797, Dec. 9. In making webs from several layers of material such as cloth or paper, each layer is treated separately with a waterproofing compn., several layers are combined into a single web, and compn. is applied between the layers. App. is described.

Annealing. FRIED KRUPP. A.-G. (Otto Hengstenberg, inventor). Ger. 504,650, May 31, 1929. A method of arranging the objects in the annealing kiln is described.

Respirator supplied with auxiliary oxygen. E. DRAGER (to O. H. Drager). Brit. 332,502, Dec. 15, 1928. Structural features of an app. suitable for use at high altitudes.

Heat insulation. HAROLD W. GREIDER (to Philip Carey Mfg. Co.). U. S. 1,782,383, Nov. 18. Various details are given of the prepn. of molded products from materials such as magnesia and asbestos mixts. mixed with water carrying air or other gas bubbles to give porosity.

Porous heat insulation. HAROLD W. GREIDER (to Philip Carey Mfg. Co.). U. S. 1,782,384, Nov. 18. A semi-fluid or plastic mixt. is formed of materials such as magnesia mixts. and water, alkali such as NaOH is dissolved and gas is generated by adding CaC_2 coated with an oily, resinous, waxy or org. fatty acid substance which reacts with the alkali to form a stabilizing agent for the foam bubbles present, and the material is molded under pressure with expulsion of water from the mold.

Electric insulation. BAKELITE CORP. Brit. 332,594, April 23, 1929. Laminated materials such as those formed from paper or cloth and a hardened synthetic resin binder are surfaced with an elec. non-cond. layer substantially free from C-contg. materials, such as asbestos in the form of paper, cloth or loose fibers which may be treated with Na silicate.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Water supply and distribution. GÜLICH. *Gas u. Wasserfach* **73**, 961–7(1930).—Modern uses have caused an enormous increase in water consumption. State surveys should be made as to available water supplies, water-bearing strata and the geological features of a given area to avoid future water famines as far as possible. Surface water supplies previously considered unusable may not be treated in a satisfactory manner, but avoidable contamination should be lessened. Several municipalities may well combine their systems for better handling of peak demands and emergencies. Water meters are desirable. The normal (German) water consumption of 80–

82 l. per capita, including industrial uses, may increase to 150 l. in hot dry weather, because of increased use for cooling foods, sprinkling, etc. Leaks cause enormous losses, up to 30–40% in old systems. R. W. RYAN

The Wanaque waterworks project. ARTHUR H. PRATT. *J. New England Water Works Assoc.* **44,** 387–450(1930).—The water supplied will be soft and of good quality; aeration for the elimination of tastes and odors is provided. The article is largely engineering in character. D. K. FRENCH

Technical features of the old Magdeburg waterworks on the Elbe. OTTO KOENIG. *Gas u. Wasserfach* **73,** 933–4(1930).—The mech. equipment is described. The quantity of free Cl in the water is controlled by the Olszewski-Sperling app. which automatically indicates the reaction of the treated water with *o*-tolidine and Zn iodide-starch soln. at definite intervals. $AlCl_3$ is used as the pptg. agent in the treating plant as it gives a quicker and better ppt. than alum, especially when pre-chlorination is used. All chemicals are handled in one building. Quick sand filtration and slow sand filtration are both used and methods of cleaning sand given. Sufficient active charcoal is added to the slow sand filter to give a layer 0.2 mm. thick on its surface and this adsorbs some org. substances, phenols, etc., so that the resultant water has a satisfactory taste, odor and color. R. W. RYAN

Water supply and dams in Japan. ALLEN HAZEN. *J. New England Water Works Assoc.* **44,** 451–7; *Water Works Eng.* **83,** 285–6, 320(1930).- The high rainfall in Japan makes possible ample storage of run off in small catchment areas. Many cases are cited where coagulation, filtration and chlorination are part of the treatment. D. K. FRENCH

Illinois River studies. C. S. BORUFF. *Ind. Eng. Chem.* **22,** 1252–5(1930); cf. *C. A.* **19,** 1745; **22,** 2630; **24,** 4105. A comparative sanitary survey of the middle portion of this river for the summers of 1929–30 is given. The data indicate that biol. O demand, dissolved O and bacteriol. load of a polluted stream are affected directly by the vol. of pollution, dilu., aeration from flow rate and by available O content. As would be expected the low water season of 1930 showed a greater pollution than that for 1929; this is based upon a lower O content and higher bacteriol. counts as criteria. Interesting curves are given. EDWARD S. HOPKINS

Filtration of Chicago water supply. LORAN D. GAYTON. *J. West. Soc. Eng.* **35,** 343–62(1930).—A rept. of the results of 2 yrs.' operation of the exptl. filtration plant built by the city of Chicago to det. whether its public water supply can be made safe and palatable. Among the main facts brought out to date are: (1) Lake Michigan water may be made perfectly clear and pure by filtration at a cost about the av. for other cities; (2) water of the highest purity is procured; (3) the water produced since Dec. 1928 excels in tests and purity the most palatable spring water; (4) water containing an abundance of microorganisms may be handled without difficulty; (5) the handling of water with high microscopical counts involves nothing that has uncertainties, (6) a method for the complete elimination of taste-producing compds. has been perfected (7) a method for handling highly polluted water has been developed; (8) the water treatment best suited will partially soften it; (9) the value of the water carried away from the exptl. plant by the public for drinking purposes is over the entire operating cost of the exptl. plant. The plant and special app. are described and numerous tables and charts shown. W. H. BOYNTON

Computation of mineral water analysis. L. FRESENIUS AND O. FUCHS. *Z. anal. Chem.* **82,** 226–34(1930).—The formulas proposed by L. Grünhut, which are given in König's *Handbuch*, are replaced by new ones which are considerably simpler. The H-ion concn. is used in place of certain empirical factors proposed by G. A table is given to show the effect of temp. upon the ionization consts. of the weak acids likely to be present and this permits an approx. correct calcn. of the condition of the weak acids at the temp. of the mineral-water spring. W. T. H.

Hydrion concentration of rain and potable water. M. C. POTTER. *Nature* **126,** 434–5(1930).—A study of the H-ion concn. of the rainfall in New Milton, England, over a period of 1½ years showed wide variations in p_H values. The rain carried by winds direct from the sea was practically neutral, while that from the direction of towns or long stretches of country tended to be acid. The data indicated that wide variations in p_H are to be expected in the rain falling upon plants. The p_H value of the surface moisture on living plants may have an important effect upon the microorganisms present. Samples of potable water taken from wells and public supplies in England gave p_H values varying from 5.0 to 9.0. LOUISE KELLEY

Shallow sedimentation basins. WILFRED F. LANGELIER. *J. Am. Water Works Assoc.* **22,** 1484–9(1930).—As the result of experience with a 1⅛-mile tunnel for subsi-

dence and sedimentation it is concluded that, in general, long, narrow and shallow basins are superior to those having greater depth and breadth. D. K. FRENCH

Hard Texas water satisfactorily softened for domestic use. ROY MASSINGILL. *Am. City* **42**, 149(1930).—The Hico, Texas, well water supply is softened by the Graver cold process using 3.05 lb. lime, 1.4 lb. soda ash and 0.25 lb. $Na_2Al_2O_4$ per 1000 gal. of water. Hardness is reduced from about 19 to 3 grains per gal. of water, and Fe is removed. The operation of the softening process whereby the chemicals are fed into the softening tank proportional to the flow of water is described. The softened water flows by gravity to 2 pressure filters and then to a 250,000 gal. covered concrete storage tank. It is then pumped to an elevated tank for distribution. Costs are given. C. H. BADGER

The use of barium aluminate in water softening. ANTONY SETON *Eng. and Boiler House Rev.* **44**, 54-6(1930).—Previous work (*C. A.* **24**, 1687) has shown that a combination of the properties of Ba and Al salts for water softening is of value in that pptn of the sulfate as well as that of Ca and Mg can both be accomplished by it. This paper indicates the chem. properties of Ba aluminate in such a procedure and suggests possible use for it as a replacement for Na aluminate. Com Ba aluminate can be obtained in powd form which is 38-40% water sol. This has an approx. compn of $11BaO.8Al_2O_3$ Lab studies indicate that from 1.5 to 2 times the theoretical amt of aluminate is needed for pptn of $CaSO_4$, $Ca(HCO_3)_2$, $MgSO_4$ and $MgCl_2$ which is 80-95% complete. Mixts. of $Ca(HCO_3)_2$ and $CaSO_4$ were pptd. by the amt. necessary for the HCO_3 alone, thereby reducing the ratio in practical water softening to that of the theoretical value of the coagulant With a mixt. of Mg salts 1/4 of the theoretical amt was adequate. The study is to be continued under industrial conditions. EDWARD S. HOPKINS

Chemical and mechanical utilization of activated carbon in water purification. W. S. BUHRMAN AND H. B. CRANE. *J. Am. Water Works Assoc.* **22**, 1399-1413(1930).—The C treatment is simple, easy of operation and inexpensive. Especial reference is made to "Hydrodarco"—the C used by the authors Several types of equipment for C treatment are described, as well as the means of application to existing plants D. K. FRENCH

Discussions of papers on activated carbon. PAUL HANSEN, R. A. HOOT, ROBERT SPURR WESTON, CHARLES P. HOOVER, W. A. HELBIG AND E. B. SHOWELL. *J. Am. Water Works Assoc.* **22**, 1462-75(1930).—The discussion emphasizes the positiveness of carbon for removal of taste and odor There is still much work to be done, largely with reference to revivification A downward rate of 2.0 gal. per sq. ft. per min. through a bed of Darco at Chester was effective The patent situation seems clear for general use of C. The theoretical reaction of C is outlined. One case where C was ineffective is described D. K. FRENCH

Activated carbon for the removal of taste and odor. GEO. D. NORCOM AND R. I. HOOD. *J. Am. Water Works Assoc.* **22**, 1414-37(1930).—A great many expts. are described involving the production of a drinking water free from appreciable odor or taste. Darco seemed superior to Nuchar or Minchar. The conditions under which different grades gave the best results are outlined. Regeneration by steam can be made very nearly complete, and the conditions giving the most complete improvement are described. Activated C can also be effectively used with certain trade wastes. D. K. FRENCH

Further observations on the use of activated carbon in removing objectionable tastes and odors from water. JOHN R. BAYLIS. *J. Am. Water Works Assoc.* **22**, 1438-61(1930); cf. *C. A.* **23**, 3765.—The results of 17 months' operation of an exptl. C unit are described in detail. Fairly deep beds gave the best results; the direction of flow is immaterial. While higher rates may be used with downward flow, more frequent washing is necessary. Methods of revivification are not yet completely satisfactory Super chlorination followed by dechlorination with active C gives the most complete satisfaction. The article is quite complete. D. K. FRENCH

Control of microscopic organisms in public water supplies, with particular reference to New York City. F. E. HALE. *J. New England Water Works Assoc.* **44**, 361-85 (1930) For controlling microscopic growths and eliminating their assocd. odors and tastes, $CuSO_4$ is most generally used. Cl is also effective and can be introduced when $CuSO_4$ cannot. The bulk of the article describes the various methods of application for the most uniform distribution and most effective action. D. K. FRENCH

Open reservoirs and the sanitary control of tap samples. C. LEROY EWING AND EDWARD S. HOPKINS. *J. Am. Water Works Assoc.* **22**, 1495-1505(1930).—*B. coli* in tap samples comes either directly from the reservoirs or indirectly from bacteria-bearing slime in the pipe lines, which from time to time is broken away and carried to the

taps. Regular chlorination of the reservoirs has greatly improved conditions. D. K. FRENCH

Significance of B. coli in water. J. KISTER. *Tech. Gemeindeblatt* **33**, 219–21 (1930).—A review of procedures for identifying *B. coli* in water. Utilization of *B. coli* tests are of great value in detg. its suitability for drinking purposes. A. L. E.

Comparison of the Dominick-Lauter presumptive test with "standard methods" test for B. coli in water. HAROLD W. LEAHY. *J. Am. Water Works Assoc.* **22**, 1490–4(1930).—A much higher percentage confirmation was obtained with the medium than with standard lactose broth. In general the new Dominick-Lauter medium which is described was found far superior to the standard procedure for the detection of *B. coli* in water. D. K. FRENCH

Some notes on the pretreatment of evaporator feed water. HUGO A. HAUPT *J. Am. Water Works Assoc.* **22**, 1345–50(1930).—Pretreatment is considered economically advantageous and necessary. Carbonate hardness reduction is the principal problem. The so-called "vaccination-process" converts carbonates into chlorides by means of HCl. Rules laid down by German users and producers of evaporators, both for construction and operation, are given. D. K. FRENCH

Action of purified feed water on the boiler equipment of the Thermo-Technical Institute. A. N. RUMYANTZEV. *Izvestiya Teplo-Tekh. Inst.* (*Trans. Thermo-Tech. Inst. Russia*) **1930**, No. 1, 12–21.—A soda-lime treatment of boiler-feed water assures a satisfactory performance of the boilers. O present in the condensate which is recycled is very detrimental to the boiler equipment. A sampling method for O detn. is described. A. A. BOEHTLINGK

Filtering materials for water and sewage works. WILLIAM E. STANLEY, *et al Proc. Am. Soc. Civil Eng.* **56**, 1851–92(1930); cf. *C. A.* **24**, 182.—This is a progress report of a comm. from the Sanitary Eng. Div. seeking to obtain information relating to the characteristics and kinds of stone for use in trickling filter beds in sewage plants The proper size of sand for water filtration is also being investigated. By use of the *unstandardized* Na_2SO_4 test for accelerating the time of disintegration of such stone comparative studies were made by 13 com. labs. throughout the country. A detailed description with tables of results is given. These tables are of practical value to those operating or designing trickling sewage-filter beds. EDWARD S. HOPKINS

The great sewage disposal plant of Berlin-Stahnsdorf. F. LANGBEIN. *Z. Ver. deut. Ing.* **74**, 1349–58(1930).—The article shows the detailed construction and engineering of the plant. Twenty-one blue-print plans are shown. RUSSELL C. ERB

Sludge problems in South Africa with special reference to sludge digestion. MARSHALL LUNDIE. *Surveyor* **78**, 497(1930); cf. *C. A.* **25**, 157.—Sludge digestion is optimum at 27–30°. Lime was added to the sludge until the p_H was 7.3–7.4. The digested sludge contained 80–90% moisture. The dry digested sludge contained N_2 3, P_2O_5 2.8, CaO 2.5 and potash 4% A. L. ELDER

Cost analysis of an activated-sludge sewage-treatment plant. WEBSTER L. BENHAM. *Am. City* **42**, 129–31(1930).—The old sewage-plant at Frederick, Okla., consisted of a screen and grit chamber, reverse-flow Imhoff tank, sludge-drying bed and chlorinating chamber. The plant was inadequate, and had been rearranged and did not function as originally intended. The new plant, designed for a 0.4 m. g. d. flow, consists of a screen chamber with overflow weir to by-pass storm water; a preliminary settling tank with hopper bottom connected to an outlet pipe from which settled sludge is pumped once a day through "Simplex" mech. surface aerators to 4 aeration tanks and 1 sludge aeration tank; a final settling tank equipped with a Dorr mech. clarifier for continual removal of settled sludge, a part of which is returned to the aeration tanks through the manually controlled sludge division box and the remainder to the sludge digestion tank which was converted from the Imhoff tank; a sludge-drying bed, the effluent from which goes to a creek, and a pump house. The clarified effluent from the final settling tank is chlorinated to overcome public prejudice. The capacities of the tanks, the periods of detention and the approx. daily elec. power requirements are tabulated. The av. daily cost is $2.03 and the cost per 1000 gal. at 400,000 gal. per day is $0.0051. The total cost of the plant and outfall sewers was approx. $35,000. C. H. B.

Guiding principles of the activated sludge process. T. CHALKLEY HATTON *Civil Eng.* **1**, 31–7(1930).—A review of the engineering and operating principles of this process based upon the work at Milwaukee. EDWARD S. HOPKINS

Contributions on sewage examinations. HERMANN BACH. *Gesundh.-Ing.* **53**, 512–6(1930); cf. *C. A.* **24**, 2819.—The standard procedures used for detg. permanganate O demand, dissolved O, biochem. O demand and relative stability of sewage are outlined. A. L. ELDER

A new reactivation of sludge without compressed air. LEINER. *Gesundh.-Ing.* **53,** 500–2(1930).—L. describes a hollow cylinder used to rotate the sewage and aerate it at the surface. The corrugated surface of the cylinder aids in increasing surface exposed and rate of circulation of the sewage. A. L. ELDER

Treatment of floating scum and gas from sludge-digestion tanks. M. PRÜSS. *Gesundh.-Ing.* 53, 548–53(1930).—Gas is collected and utilized. Floating scum causes considerable trouble. Spraying of incoming sludge and recirculation of partly digested sludge keep the floating scum at a min. A. L. ELDER

Observations on surface scum in Emscher tanks in the Ruhr district. K. IMHOFF. *Tech. Gemeindeblatt* 33, 203–6(1930).—Observations on 27 tanks are reported. Data for these plants are summarized. In general, surface sludge is a function of exposed area of the tank surface. Gas collectors have been placed on 21 of the 28 tanks. A. L. ELDER

The permissible load of sewage in streams. MAHR. *Tech. Gemeindeblatt* 33, 189–94(1930).—An attempt is made to develop an equation by which one could calc. the permissible load of sewage in a stream. The quantity of both dissolved and undissolved materials present in the sewage must be known, as well as the biochem. O demand of the waste, the quantity of diln. water and amt. of reaeration in the stream. A. L. ELDER

Some experiences with trade effluents. J. HURLEY. *Surveyor* **78,** 493–5(1930).—Treatment of gas liquors with aluminoferric at the rate of 0–15 grains per gallon improved the quality of the effluent but slightly. Twenty % solns. of dye waste in water could be decolorized by use of 5 grains per gallon of aluminoferric. Limestone filters surfaced with clinkers proved most effective in treating mixts. of industrial wastes and domestic sewage. The Shipley urban district has taken over a contract with the various industries to treat the industrial wastes. A. L. ELDER

Two-stage tanks for waste containing phenol in Hattingen. FRANZ FRIES. *Tech. Gemeindeblatt* **33,** 206–10(1930).—Drawings are given of the plant designs. Raw waste contg. 45.4 mg. per l. of phenol was so well purified that the effluent contained only traces of phenol. A. L. ELDER

The ozone plant for the assistance of the ventilating arrangement in the legislative building at Dresden. H. HOSCHMIEDER. *Gesundh.-Ing.* **53,** 499–500(1930).—Ozone has been satisfactorily used to purify and recondition air in this building. A. L. E.

Ventilation of cinemas: some medical aspects. W. S. WALTON. *J. Roy. Sanitary Inst.* **50,** 686–91(1930).—CO_2 as high as 0.54% was found in one theater. The CO_2 was detd. by Pettenkorfer's method. For physiol. comfort he recommends that the temp. be kept at 58–68°F., the wet bulb temp. 5–6°F. lower than the dry bulb, and the CO_2 content of the air be kept at less than 20 parts per 10,000 parts of air. A. L. ELDER

A condenser for low-temperature evaporation of H_2O (EVANS, *et al.*) **1.** Organic matter, P and V in the Black Sea deposits (ARKHANGELSKII, KOPCHENOVA) **8.** Ti acid sulfate (U. S. pat. 1,783,684) **18.** Catalytic zeolites (U. S. pat. 1,782,353) **18.**

Purifying water with activated carbon. ROY L. HILL (to Darco Corp.). U. S. 1,782,850, Nov. 25. A natural water is mixed with a very small proportion of activated C, and the water contg. the C in suspension is then given a slow rotational velocity which may be about one or two turns per hr. about the axis of a cylindrical tank, to produce an accelerated settling of the carbon. App. is described. Cf. *C. A.* **25,** 158.

Apparatus suitable for distilling water, etc. WILLIAM S. ELLIOTT. U. S. 1,782,959, Nov. 25. Structural features.

Apparatus for softening water by treatment with base-exchange material. FRANK W. MILLER (one-half to Ira J. Wilson). U. S. 1,783,255, Dec. 2. Structural features.

Apparatus for softening water with zeolites. ROBERT O. FRIEND. U. S. 1,783,466, Dec. 2. Structural features.

Apparatus for deaerating water by cascading and steam treatment. W. BOBY and W. BOBY & Co. Brit. 332,678, May 23, 1929. Structural features.

Apparatus for carbonating water. FREDERICK NEUSCHAFER and HARRY BOTWIN. U. S. 1,782,511, Nov. 25. Structural features.

Apparatus for separating oil, etc., from water. DEUTSCHE ABWASSER-REINIGUNGS-GES. M. B. H. (Otto Mohr, inventor). Ger. 506,074, Mar. 19, 1929.

Apparatus for filtering sewage. JOHN PUGLIESE. U. S. 1,783,341, Dec. 2. Structural features.

Apparatus for filtering liquid materials such as sewage and industrial effluents.

CHARLES T. CABRERA (to Electro Dialyzer Corp.). U. S. 1,784,132, Dec. 9. After upward filtration, filtered liquid passes into an annular trough surrounding the filter where it may be agitated and aerated. Various structural details of the app. are described. Cf. *C. A.* **24**, 1254.

Apparatus for treating sewage with activated sludge. FRIEDRICH SIERP and FRANZ FRIES. Ger. 506,337, June 25, 1927. Addn. to 486,071 (*C. A* **24**, 1919).

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Studies on the chemistry of soils. LUDWIG WOLF. *Z. angew. Chem.* **43**, 922–8 (1930).—In studying the compn. of soils, the old method consists in first screening the soil particles below 2 mm. size into fractions: 2–0.2, 0.2–0.1, 0.1–0.05, 0.05–0.01 mm and less than 0.01 mm. diam. The first 3 fractions consist mainly of sand and W. proposes to designate these fractions as the passive part of the soil and the smaller 2 fractions as the active part. For practical purposes soils can be characterized by their sand content. A new method is proposed for elutriation analysis of soils consisting in centrifuging the soil particles in aq. medium. The centrifuge consists of 3 chambers sepd from each other by means of concentric screen walls. These screens divide the particles in 3 sizes: those larger than 0.08 mm., 0.18–0.12, and 0.12–0.05 mm. diam. Particles less than 0.05 mm. size pass out with the H_2O from the third chamber. Thus the passive part of the soil is retained in the drum and is divided into 3 fractions, while the active part comes out separately. The whole process takes only 15 to 40 min. The CaO requirement of the soils is detd by the p_H content. Soils contg. an excess of CaO will have a p_H characteristic for H_2O satd. with $CaCO_3$. In this way, soils giving a p_H greater than 9 show an excess of $CaCO_3$, while those contg. a p_H less than 9 are deficient in $CaCO_3$. More accurate and consistent results are obtained when p_H measurements are made on the finer or active fraction of the soil which is not retained in the centrifuge. The Daikuhara value of soils for Al Fe salt hydrolysis is found to depend on the p_H value. This fact is proven by a series of expts. Electroosmosis has the same effect as the H ion on kaolin and Al_2O_3, the carriers of Al salts in the soils, in increasing their tendency to replace K from its salts, thus increasing the Daikuhara value of the soils. S. L. M.

The essential component of the acid soil of Japan and a theory of its actions. N. KAMEYAMA AND S. OKA. *Caoutchouc & gutta-percha* **27**, 15239–40(1930).—See *C. A.* **24**, 3328. C. C. DAVIS

An improved soil sampler. I. J. PESSIN. *Science* **72**, 459–60 (1930).—A sampler described composed primarily of a 1 in. galvanized pipe which has a $\frac{3}{4}$ in. slit along its length. One edge of the slit has a cutting edge and the other is dull. In practice the tool is simultaneously thrust into the ground and gradually turned. When withdrawn from the soil it carries a cylindrical core of slightly compacted soil, whose phys. structure is but slightly affected. J. R. ADAMS

Predetermination of soil corrosion. J. F. PUTNAM. *Oil and Gas J.* **29**, No. 26, 158, 159, 187(1930).—A simple ammeter-voltmeter test can be used to predet. the corrosiveness of soil. The method gives close correlation with corrosion experience. CHAS WIRTH

Carbon dioxide production in sands and soils in the presence and absence of amebae. D. WARD CUTLER AND L. M. CRUMP. *Ann. Appl. Biol.* **16**, 472–82(1929).—CO_2 production from soil and sand cultures contg. a species of bacterium with and without amebae was studied. CO_2 production and bacterial nos. are correlated if amebae are not present or are present only in very small nos. The bacteria are more efficient as producers of CO_2 when their nos. are not increasing, less efficient when their nos. are increasing. This is not true of young cultures. Each bacterium becomes less efficient as the population increases in density. The amebae cause a decrease in CO_2 production in sands contg. peptone, an increase in sands contg. mineral salt soln. with glucose or soil ext. C. H. RICHARDSON

Will synthetics completely displace organic ammoniates? G. P. WALTON. *Chem. Met. Eng.* **37**, 619–22(1930).—The progressive decline in the use of org. N in com. fertilizers since the World War has fallen primarily on animal tankage, dried blood, cottonseed meal and fish scrap. Any upward trend will probably cause an increase in the production of fertilizer from municipal sewage and garbage, fish offal, peat and nitrogenous "tankages" from addnl. crude ammoniates and waste materials. J. R. ADAMS

Absorption of phosphoric acid by plants. R. RUDEL AND KLEBERGER. *Das Superphosphat* **6**, 163–6(1930).—The relative values of superphosphate, Rhenania phosphate and Thomas meal as sources of P_2O_5 were detd. in a 3-year field expt. with summer barley. P_2O_5 absorption was more rapid and complete from superphosphate and Rhenania phosphate than from Thomas meal, particularly during the earlier stages of growth. For the mature plants the relative absorption was 100:91:77, while just after blooming it was 100:74:60. In the same order, the total relative yield of mature grain and straw was 100:98.5:96.5, while the relative yield of grain was 100:96.5:91.5. The phosphatic materials gave identical yields of mature straw. K. D. JACOB

Absorption of phosphoric acid by plants from air-dry and heated soils of different acidities, as determined by the Neubauer method. KARL SCHUMANN. *Das Superphosphat* **6**, 180–2(1930).—In expts. with 9 varieties of plants on 3 types of soils, larger amts of P_2O_5 were absorbed, in general, from soils heated for 24 hrs. at 80 100° than from the air-dry soils, as detd. by the Neubauer method. The largest amts. of P_2O_5 were absorbed from the soil having a p_H of approx. 6, and absorption of P_2O_5 from this soil was affected more by heating than with soils having higher and lower p_H values. The highest abs. absorption of P_2O_5 was obtained by the use of lupine as a test plant, rye giving the next best results. K. D. JACOB

Absorption of phosphoric acid and potash in Neubauer plant germination experiments. A. HOCK. *Das Superphosphat* **6**, 167–72(1930).—Some of the factors involved in the absorption of P_2O_5 and K_2O by plants, as detd by the Neubauer method, were investigated. In pure sand culture, complete absorption of K_2O was obtained when 25 mg. of K_2O was applied in the form of KCl. With 50 mg. of K_2O 90% absorption was obtained, and with 100 mg 83%. An abs. max absorption of 85 mg. was obtained from 150 mg. of K_2O. Approx 70% of the P_2O_5 was recovered when 15 mg. of P_2O_5 was used in the form of Na_2HPO_4. The percentage recovery decreased rapidly as the amt. of P_2O_5 was increased, being only 20% with an application of 75 mg. of P_2O_5. When P_2O_5 and K_2O salts were used together higher recoveries of both were obtained than when each was used alone in equiv. amts., the absorption of P_2O_5 being affected much more than that of K_2O. Addn of $NaNO_3$ markedly increased the recovery of P_2O_5 but did not greatly affect the absorption of K_2O. $CaCO_3$ depressed the absorption of P_2O_5 but had no effect on the K_2O. Higher recoveries of both P_2O_5 and K_2O were obtained when the salts were added to the lower sand layers than when they were added to the upper layers. K_2O and P_2O_5 were not absorbed in equiv. amts. from KH_2PO_4, the former being absorbed in the greatest quantity. As detd. by the amts. of P_2O_5 absorbed, $Ca_3(PO_4)_2$ was less than 50% as effective as equiv. quantities of CaH_2PO_4. K. D. JACOB

Brief study [of reasons for] beneficial action of brown coal upon development of cultivated plants. A. KISSEL. *Braunstaff-Chem.* **11**, 257–60(1930).—The use of org. constituents of coal in agricultural fertilization is discussed. Relative growth rates of wheat planted upon untreated soil and soil treated with pulverized coal have been detd. and are shown graphically. Explanation of the responsibility of coal decompn. for these effects is attempted with soil temp. studies, relative data are also shown by graphs. F. W. JUNG

The fertilizer treatment of the cane crop. P. J. CILLIERS. *S. African Sugar J.* **14**, 543–7(1930). A scheme for the fertilizer treatment of the cane crop in South Africa is outlined. The length of time of cultivation and the fertility of the soil are taken into consideration. Various fertilizer mixts. and rates of application are given. The large phosphate requirements are emphasized. From 6 to 10% of potash, depending on the soils, is necessary. Where N is lacking application of $NaNO_3$ should be profitable. F. W. MARSH

Fertilizing experiments on Hevea. III. J. GRANTHAM. *Arch. Rubbercultuur* **14**, 353–6(1930)(in English 345–50), cf. *C. A.* **22**, 477.—The present paper gives further results during the last 3 yrs of the "2nd nitrate manuring expt.," in addn. to new expts. on red liparite tuff soil. The nitrate fertilizing resulted in increased yields in all cases. On the red soil, with combined N and phosphate fertilizing the beneficial effect was proved to be due to the N and not to the P. C. C. DAVIS

Effects of certain alkaloids, glucosides and other substances upon the infectivity of the mosaic tobacco juice. T. FUKUSHI. *Trans. Sapporo Nat. Hist. Soc.* **11**, 59–69(1930); *Rev. Applied Mycol.* **9**, 747.—The virus of tobacco mosaic proved remarkably resistant to various kinds of alkaloids. It resisted a satd. soln. of aconitine and nearly satd. solns. of morphine sulfate, strychnine sulfate, salicin (all at 2%), phlorhizin (3%), brucine (1%), digitalin (2%) and amygdalin (5%) for 5 days. Mustard oil and digitalin (2 and 5%, resp.), destroyed the virulence of the mosaic juice in 5 days. Nicotine

(3%) caused a marked reduction in the virulence of the mosaic juice in 3 hrs. and destroyed it in 3 to 5 days and the same effect was produced by atropine (1%) in 3 days and at 2% in 1 to 3 days. Saponin (2%) failed to reduce the infection of the virus and 10% soln. did not completely destroy it in 5 days. O. E. SHEPPARD

Vegetable oils as fungicides. H. MARTIN AND E. S. SALMON. *Nature* **126**, 58 (1930).—On powdery mildew of the hop (*Sphaerotheca humuli*) greenhouse expts. showed that 0.5% emulsions of olive, sesame and cottonseed oils and 2.0–3.0% emulsions of rape oil were completely fungicidal while 2.0% emulsions of castor oil were not. 0.5% soft soap was the emulsifier used. It was found that the emulsifier had a marked effect upon the toxicity of the spray. Many vegetable oils in comparatively high concns. showed no injurious effects on the foliage. F. W. MARSH

Investigations on the fungicidal action of sulfur. IV. Third progress report. B. T. P. BARKER. *Ann. Rept. Agr. and Hort. Res. Sta., Long Ashton, Bristol for 1929* 130–48(1930); *Rev. Applied Mycol.* **9**, 732–3; cf. *C. A.* **23**, 5267.—In further attempts to identify the reducing substance or substances formed by living plants which culminates in the reduction of S to a sulfide it was observed that yeasts were especially effective and pressed yeast was found as a satisfactory substance to study. Evidence indicated that the reducing mechanism can function apart from the organism, whether living or dead. The evidence indicates that the sulfuring of a plant leads to the formation of a S compd. more or less resistant to temps. up to 100° but which is decompd. on the addn. of a mineral acid when H_2S is liberated. The reducing factor retains its activity after treatment with an alkali but loses it on treatment with dil. H_2SO_4. Conclusion: The S reducing action takes place outside the organism and is effected by means of a substance or substances emerging from the plant. The H_2S would account for the fungicidal value of S. In a foot note it is stated that further results point to a glutathione (probably identical with the hypothetical "philothion" of de Rey-Pailhade) as the reducing factor. O. E. SHEPPARD

Dry corrosives containing copper. F. X. SCHWAEBEL. *Z. Pflanzenkrankh. u. Pflanzenschutz* **40**, 113(1930).—Cu salt "W," a basic $CuCl_2$, is recommended as a cheap, effective dry corrosive for combating seed smut (*Tilletia*). C. W. SONDERN

Copper and mildew. G. VILLEDIEU. *Prog. agr. vit.* **94**, 373–6(1930).—Expts. were conducted on immunization and the use of powders in combating mildew, oidium, cochylis and eudemis. A material which will inactivate the mildew diastase is being sought. Cu, in the proper chem. form, was introduced into some plants. Newly developed foliage on these plants was much superior to that on untreated specimens but in August the treated plants were in poor condition because of mildew invasion. The use of ammoniacal salts makes the vines more susceptible to mildew through an exaggeration of the foliage growth. F. W. MARSH

Spraying experiments for black spot and powdery mildew. H. A. TURNER AND W. J. DOWSON. *Tasmanian J. Agr.* [N. S.] **1**, 101–2(1930); *Rev. Applied Mycol.* **9**, 725. —Spraying with a carbide mixt. (2 lb. Cu sulfate, 12 oz. Ca carbide and 40 gals. water was compared with spraying with lime sulfur and Bordeaux on Jonathan, Dunn and York apples in Tasmania. The results compared very favorably, especially when the carbide mixt. was applied at the green tip stage, with the rest. The important advantages of the carbide mixt. are its ease of prepn., its greater adhesiveness as compared with lime sulfur, and the fact that it did not cause leaf scorch though there was some russeting. O. E. SHEPPARD

The effect of copper sulfate on tomato plants. O. OWEN. *Ann. Appl. Biol.* **16**, 430–7(1929).—This is a study of the effect of Cu in the soil on tomatoes at various stages of growth. The addn. of $CuSO_4$ increases the rate of germination, but total germination is unaffected and subsequent growth is not satisfactory. The toxicity of Cu is greater in the form of $CuSO_4$ than as "Chestnut compd." (a mixt. of 11 parts $(NH_4)_2CO_3$ and 2 parts $CuSO_4$ dissolved in water in the amt. of 1 oz. mixt. in 2 gallons). When used to control "damping off" of tomato seedlings and foot rot Chestnut compd. is harmless to the soil. The addn. of new soil around the stems and the application of $Ca(OH)_2$ are beneficial when the soil has become poisoned with Cu. Small quantities of $CuSO_4$ in the soil have no effect on the no. of seeds per fruit and on the ability of the seeds to germinate but the seedlings subsequently produced are commercially unsatisfactory. C. H. RICHARDSON

The determination of the degree of incrustation of the disinfectant on dusted seed grain. G. HILGENDORFF. *Nachrichtenbl. Deut. Pflanzenschutzdienst* **10**, 33(1930); *Rev. Applied Mycol.* **9**, 707.—The dusted seed is shaken repeatedly with ether to remove the disinfectant, which is recovered by evapn. The residue is dissolved in AcOH, the As oxidized by Br water and the Cu content detd. by titration with Na thiosulfate after

the addn. of KI. If the Cu content of the disinfectant is known the amt. of the disinfectant used can readily be calcd. The method accounts for 95% of the disinfectant adhering to the seed grain when tillantin is used and H. claims it is equally applicable for tutan, Cu carbonate and like dusts. O. E. SHEPPARD

Nicotine in grape growing. L. FERRÉ. *Rev. vit.* **73**, 178–84(1930).—Microchem. detns. by the method of Bertrand and Jauillier showed that nicotine used as an insecticide on grapes soon disappeared; this was due in wet weather to the action of the rain and, in dry weather, to volatilization. Conclusion: Nicotine may be thus used without the slightest disadvantage. F. W. MARSH

Results of experiments with sodium nitrate on some varieties of wheat. P. AURIUEL. *Prog. agr. vit.* **94**, 210–1(1930).—$NaNO_3$ increased the yields, especially of straw, from all plots when applied during a 3-month period at the rate of 200 kg. per hectare. F. W. MARSH

Contributions to the control of potato wart. J. LEMMERZAHL. *Phytopath. Z.* **2**, 257–320(1930); *Rev. Applied Mycol.* **9**, 738–9.—Soil disinfection by the use of crude benzene at the rate of 500 cc. per 3500 cc. soil, 3% formalin at the same rate, 3% cresolsulfonic acid at the same rate and chloride of lime at the rate of 12 g. per 3500 cc. soil was used in greenhouse expts. All methods were partially effective but none gave complete control in the field. Crude benzene (28 l. per sq. m.) was the most satisfactory, followed by 1% formalin (35 l. per sq. m.). O. E. SHEPPARD

Significance of the work of J. M. van Bemmelen in regard to the knowledge of the soil (HISSINK) 2.

Selectively sterilizing soil. CHARLES HARNIST. Ger. 506,484, Feb. 28, 1923. Compns. which promote the growth of anaerobic, N-assimilating bacteria, but destroy aerobic organisms, are prepd. by heating waste vegetable materials, *e. g.*, wood shavings, with alkali or alk. earth salts of oxygenated acids of S in the presence of water, if desired under pressure, and filtering off the soln. A suitable compn. may also be prepd. from sulfite cellulose lye by treating it with NH_3 and SO_2 in turn, in order to remove constituents having resinous, gelatinous and tanning properties, the residual soln. being the desired product. The action of the products is ascribed to the presence of lower oxygenated acids of S. Fertilizers, etc., may be added to the compns. Examples are given.

Phosphatic fertilizer. A. HOLZ and T. VAN D. BERDELL. Brit. 332,750, July 30, 1929. See Can. 303,903 (*C. A.* **24**, 5419).

Phosphate fertilizers. ARMOUR FERTILIZER WORKS. Brit. 332,639, April 25, 1929. See Fr. 674,443 (*C. A.* **24**, 2538).

Phosphates and other fertilizing salts. F. UHDE. Brit. 332,803, Oct. 25, 1928. An alkali or NH_4 sulfate is added to raw phosphates treated with HNO_3, thus pptg. $CaSO_4$, and a Mg salt such as $MgCl_2$ from the potash industry is added prior to or subsequent to removal of the $CaSO_4$ (or $MgSO_4$ may serve both functions). NH_3 may be added and various details and modifications of the procedure for prepg different products are described.

Organic iron compound suitable for use as a plant stimulant. HENRY BLUMENBERG, JR. and JOHN H. BLUMENBERG. U. S. 1,783,694, Dec. 2. Comminuted cellulose material such as sawdust is treated with an aq. Fe sulfate soln. and the impregnated material is heated until it assumes a dark brown or black color.

Stimulant and parasite-destroyer for plants; fertilizer. PAUL SCHMIDT. Ger. 506,485, May 20, 1927. A ground mixt. of quicklime and $MgCl_2.6H_2O$ is left to react, without addn. of H_2O as such, until a dry product contg. $Mg(OH)_2$, Mg_2OCl_2, Ca_2OCl_2, and $CaCl_2$ is obtained. The product may be emulsified and applied by spraying.

Insecticides. I. G. FARBENIND. A.-G. (Carl Taube and Hans Kükenthal, inventors). Ger. 506,085, Nov. 27, 1928. Compds. contg. a CNS and a thioether group are used, alone or with the usual addns. Suitable compds. are *1-methylthiol-4-methylthiocyanomethylbenzene*, m. 55°, and *1-methylthiol-4-chloro-2-thiocyanomethylbenzene*, m. 60°, each prepd. by the action of alc. NH_4CNS on the corresponding halogen compd. Cf. Ger. 501,135 (*C. A.* **24**, 4578).

Insecticides, etc. CHEM. FAB. LUDWIG MEYER. Ger. 506,428, Sept. 12, 1929. Insecticidal or fungicidal dusting powders comprising PhOH, an inert filler, and a readily vaporized substance, *e. g.*, nicotine or a Hg compd., are prepd. with the use of cryst. PhOH, which is melted and mixed with the filler, etc.

Finely divided sulfur mixture suitable for use on plants or trees. HENRY BLUMEN-

BERG, JR. U. S. 1,783,695, Dec. 2. A mixt. of S 90 and H_3BO_3 10% is heated to 130–300° to produce a powdery product which may be used as an *insecticide* and *fungicide*.

Fungicidal composition for treating seeds. HEINRICH RÖSSNER, ADOLF STEINDORFF and KASPAR PFAFF (to Farbwerke vorm. Meister Lucius and Bruning). U. S. 1,783,200, Dec. 2. A metal-contg fungicidal compd. such as Cu carbonate 30 is mixed with an inert "extender" such as kieselguhr 32–48, a resin sulfonate 30–40 and an oily material such as spindle oil, bone oil or train oil about 2–3 parts. Cf. *C. A.* **24**, 196.

Disinfectant for seeds. MAX ENGELMANN (to E. I. duPont de Nemours & Co.). U. S. 1,783,377, Dec. 2. See Brit. 329,672 (*C. A.* **24**, 5928).

Insecticide. ALBERT HARTZELL (to Boyce-Thompson Institute for Plant Research, Inc.). U. S. 1,781,841, Nov. 18. Minute particles of colloidal sublimed S are carried in an emulsion of fish-oil soap and water. Cf. *C. A.* **24**, 5104.

Sulfurous insecticides for treating plants. J. STODDART. Brit. 332,638, April 25, 1929. A soln. of S (suitably in CS_2) is added to finely divided kaolin to produce a product contg. 10% or less of S and the solvent is driven off; or solid S may be added to kaolin and the mixt. then heated to above the vaporizing point of S.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Some modern developments and future possibilities in the industrial application of fermentation phenomena. T. K. WALKER. *Chemistry and Industry* **49**, 946–8(1930). E. H.

The chemical approach to problems of fermentation. ELLIS I. FULMER. *Ind. Eng. Chem.* **22**, 1148–50(1930).—The nature and complexity of the chem. changes brought about by the action of microorganisms on carbohydrates are pointed out. The influence of the environment on the phys. and chem. changes is discussed. A chart is given which shows the interrelationships existing between the substrates and the products of fermentation. Fermentation products are not always degradation products. Synthesis may be involved. Synergism, or the effect of different organisms growing together which bring about chem. reactions not taking place when the organisms are grown alone, is discussed. C. N. FREY

Development of the butyl-acetonic fermentation industry. C. L. GABRIEL AND F. M. CRAWFORD. *Ind. Eng. Chem.* **22**, 1163–5(1930).—The history of the development of the butyl-acetonic fermentation industry is presented. An outline of the commercial processes used is given. The uses of the products of fermentation are discussed. The rationalization of the industry by the development of uses for all the by-products is briefly discussed. C. N. FREY

Influence of catalytic elements on alcoholic fermentation. II. M. ROZENBLAT AND A. MARCH. *Biochem. Z.* **226**, 404–14(1930).—In the absence of nutritive substances no metal element accelerates the yeast fermentation; apparently the metals merely stimulate the growth of yeast which in turn causes an increase in fermentation. Alc. fermentation occurs even in the presence of a high concn. of the metals, exceeding very greatly the concn. necessary completely to paralyze the development of yeast. Thus with Co this concn. may be 100 times as great. Likewise, the series of metals in the order of their paralyzing action on the zymase system of the yeast differs from that in the order of their effect upon the growth of yeast. Ni is the most toxic from both points of view. Ni > Fe > Co, Mn is the order of their effectiveness on the zymase, which is also like their effectiveness on pepsin. The Fe^{+++} is a more efficient paralyzer than Fe^{++}, and in a 0.2% concn. of the former less than $1/_{20}$ as much sugar is fermented as of the latter. S. MORGULIS

Ethyl alcohol. A. A. BACKHAUS. *Ind. Eng. Chem.* **22**, 1151–3(1930).—The origin of the EtOH industry is described. A table showing the increased growth of the industry since 1907 and the uses of industrial alc. is included. The process used in carrying out large fermentations of molasses mashes is described. The theory of alc. fermentation as developed by Harden and by Neuberg is discussed. C. N. FREY

Lactic acid. J. F. GARRETT. *Ind. Eng. Chem.* **22**, 1153–4(1930).—The history of the lactic acid industry in America is given. Lactic acid is produced by comparatively high temp. fermentation, the raw materials usually consisting of cane or beet sugar, corn starch or corn sugar. A pure culture of lactic acid bacteria is usually employed. The recovery is conditioned by the product desired, whether for technical purposes or for use as a food product. The uses of lactic acid are briefly discussed. C. N. F.

Report on (the analysis of) vinegar. ARTHUR M. HENRY. *J. Assoc. Official Agr. Chem.* **13**, 471–5(1930).—Addn. of 1 g. of sugar in the *detn. of ash* in vinegar by the A. O. A. C. method reduces the no. of water treatments, reduces the time required for ashing, and improves the character of the charred residue and the final ash. The use of MgO cream and neutral $Pb(OAc)_2$ (with removal of excess Pb) for clarifying vinegar in the *detn. of polarization* has very little, if any, effect on the reading, the variations being within the exptl. error; the use of vegetable decolorizing carbons gives wide variations and a tendency to give a + error. Clarification with neutral $Pb(OAc)_2$ and removal of excess Pb is considered the best method. In the *detn. of glycerol*, a 1% $PhNH_2$ soln. in concd. H_2SO_4 has been used satisfactorily as inside indicator instead of $K_4Fe(CN)_6$ as outside indicator in the final titration. A. PAPINEAU-COUTURE

Discolorations in vinegar. HEINRICH KREIPE. *Deutsche Essigind* **34**, 425–7 (1930).—Certain discolorations observed from time to time in vinegar may be ascribed to Fe and tannin. W. O. E.

The concentration of musts. M. J. DUBAQUIÉ. *Prog. agr. vit.* **94**, 369–71(1930).—Concn. increases the food value of wine and decreases the amts. to be marketed. Acidity is not increased. Economies are discussed. F. W. MARSH

Application of adsorption to the sterilization of wines. PHILIPE MALVEZIN. *Prog. agr. vit.* **94**, 262–4(1930).—The addn. of kieselguhr to wine, subsequently centrifuged, greatly increased the disease organisms pptd. and left the liquid free from them. Adsorption phenomena induced by the addn. of kaolin resulted in a sterilization of the wine, when filtered, without effecting vitamins, etc., and chem. properties. Also in *Bull. soc. chim.* **47**, 1194–6(1930). F. W. M.

The study of hybrid wines. E. KAYSER. *Rev. vit.* **73**, 279–81(1930), cf. *C. A.* **24**, 2541. Analyses by the usual methods were made on several hybrid wines. F. W. M.

Treatment of wines with ozonized air. P. MARSAIS. *Rev. vit.* **73**, 311–4(1930).—Six different types of wine, including a white wine whose fermentation was stopped at 1% with S, were treated with ozone mixed with air in various proportions, regulated by the ozonator power input. The rapidity of the reactions was increased with higher wattages but the final results were the same at points of 36–60 w. The alc. contents changed but little; volatile acids remained const. or decreased somewhat; while the fixed acids did not change. The color of the red wine became lighter in intensity. The quantities of sulfurous anhydride found free and combined varied with the amt. and rate of current application. Iron salts were pptd. The taste of a hybrid wine was markedly modified. Yeasts, certain disease producing organisms and acetic bacteria did not multiply in treated wine. The *Mycoderma vini* developed in partly filled samples. Careful filling would probably obviate these. The taste was flat directly after treatment but the savory and odorous characteristics reappeared on standing.
F. W. MARSH

The evolution of "tourne" in cement vats. FONZES-DIACON. *Prog. agr. vit.* **94**, 87–9(1930). Chem. analyses of wine samples taken in June from a 30-yr. old cement vat show that the development of the disease ("tourne") was from the top to the bottom, in contrast to its usual action. This is attributed to the poor heat cond. of the thick bottom walls and the better heat transmission of the thinner walls at the top. A favorable temp. for biological action is thus maintained at the top. F. W. MARSH

The boiling of worts. LOUIS LOTTIN. *Bull. assoc. élèves inst. sup. fermentations Gand* **31**, 286–8(1930). A brief address. A. PAPINEAU-COUTURE

The ratio between the solid content and the specific gravity in wort and beer extract. C. N. RIBER. *Kgl. Norske Videnskab. Selskabs Skrifter* **1929**, No. 2, 1–22.—The solid content of wort and beer is very difficult to det. directly on evapn. to const. wt. because the last traces of water are difficult to expel from the sirupy residue. For this reason breweries have for a long time detd. the sp. gr. only and from a table read off the corresponding content of sugar. It has been assumed that the ratio between the sp. gr. and the percentage of solids in these liquids is the same as that for aq. sugar solns. This assumption only holds for approx. values and the table, constructed by Balling for this purpose, was found to be inaccurate for sugar also. In previous work (*Christiania Videnskab. Selskabs Skrifter, I. Math. naturv. Klasse* **1897**, No. 5) it was shown that on drying the ext. absorbed in filter paper in rotating, evacuated tubes const. wt. could be reached at a temp. low enough to avoid destruction of the residue. The values thus found showed that the solid content at a certain sp. gr. was not the same for all kinds of beer and wort, but the differences were so small that they could be disregarded. In the most unfavorable cases the deviation for 10% exts. did not exceed 0.1%. A standard table was worked out which could be used for all kinds of exts. Special tables were given for cases where a greater accuracy was required. All weighings were re-

duced to vacuum; otherwise an inaccuracy of about ±0.0003 in the sp. gr. could occur, while this must be kept below ±0.0001. The original standard table which was based on d_{15}^{15} is in the present work recalcd. to d_{20} and the values g. per l. ext. are given besides g. per 100 g. ext. in accordance with the international analysis convention of 1912. A new *pycnometer with counterbalance* had been constructed (*Chem.-Ztg.* **27**, 94(1903)) with which the circumstantial calcns. in reducing the weighings to vacuum were avoided The pycnometer may also be employed for liquids lighter than water. By means of a special arrangement the abs. sp. gr. may be detd. in a few min. with an accuracy of ±0.0001. D. THEUSEN

Turbidity (of beer) due to yeast. P. PETIT. *Brasserie & malterie* **20**, 209–12, 225–8(1930).—A discussion of the importance of proper filtration in the prevention of the development of turbidity in bottled beer due to the development of yeasts. At the present time double filtration, with a very close filter mass for the 2nd filtration, generally gives quite good results, but with no abs. assurance of the complete elimination of all the yeast cells; and it is suggested that builders of filters should develop a type that would eliminate all cells in a single filtration. A. PAPINEAU-COUTURE

The p_H value of beer. CH. DE GRONCKEL. *Bull. assoc. élèves inst. sup. fermentations Gand* **31**, 289-300(1930).—A study of the effects of the various factors affecting the

[illegible] the temp. of fermentation produces a slight increase in the free acidity of the beer. (4) Buffering of the worts in the p_H range over which alc. fermentation takes place seems to be the only factor having a preponderating influence on the phenomenon; it is necessary not to exceed a definite degree of buffering so as not to reduce the free acidity at the end of fermentation and the stability of the beer which depends on it. (5) The amino acids are the chief buffers of the wort; as long as they are present in such amts. as to be completely assimilated by the yeast, they increase the free acidity at the end of fermentation, but if an excess remains which has not been assimilated, they act as buffers and oppose any increase in the H-ion concn. From a brief discussion of the means available for controlling the amino acid content of the wort, de G. considers that the principal one consists in low-temp. malting; moreover, proper aeration during fermentation facilitates more complete assimilation of the N, which has the 2-fold advantage of decreasing the amt. of yeast foods in the finished beer, and of decreasing the amt. of buffer compds., thus facilitating an increase of the H-ion concn. to the optimum (p_H about 4.0). A. PAPINEAU-COUTURE

History and development of the modern yeast industry. CHARLES N. FREY *Ind. Eng. Chem.* **22**, 1154–62(1930).—A brief history of the yeast industry is given Various theories of fermentation which have arisen during the course of the development of the industry are described. The development of the ammonia-molasses process is discussed. The uses and biological properties of yeast are given. C. N. FREY

Fermentations in the food industries (BLANCK) **12.** Monosaccharide material from hydrolysis of starch liquor (U. S. pat. 1,784,402) **28.**

Concentrating aqueous alcohol. CARL HANER (to Publicker, Inc.). U. S. 1,783,086, Nov. 25. An alkali hydroxide is dissolved in the aq. alc. mixt.; it is heated and a distillate of higher alc. content than the const. b. p. mixt. is condensed and removed from the system; a distillate of lower alc. content is thereafter condensed and removed from the system, and the distn. is stopped with sufficient alc. and water remaining with the alkali hydroxide to keep it in liquid condition at the temp. of distn.

Ethyl alcohol gel. HEINZ OHLE and JOHANNA OTHMAR-NEUSCHELLER. U. S. 1,783,133, Nov. 25. Gels from which the alc. can be sepd. by heating or compressing are prepd. by use of alkali metal or alk. earth metal salts of the sulfuric acid half esters of acetone derivs. of sugars and multivalent alcs. such as diacetone-glucose, diacetone-galactose, α- and β-diacetone-fructose and acetone-glycerol.

Fermenting fruit materials, etc., for producing alcoholic liquors. WINCENTY MATZKA. U. S. 1,781,788, Nov. 18. For the fermentation of materials such as fruit culls or residues such as those of pineapple, lemons, oranges or grape fruit (preferably with added sugar and in a slightly acid medium), a ferment is used which does not destroy the natural aroma of the vegetable material and which has been prepd. by propagation in a body of aq. liquor of the same character as that to be fermented. Various details for prepg. a Saccharomycetes culture and its use in the main fermentation process are described.

Yeast. JOHN H. BARRINGTON (to Standard Brands, Inc.). U. S. 1,784,618, Dec. 9. A process is described in which a mixed molasses and grain mash is soured by lactic fermentation, yeast is propagated with acration in a nutrient soln. prepd. from the soured mash, with addn. of aq. NH_3 during one stage of the propagation and of $(NH_4)_2SO_4$ during a later stage, to keep the acidity of the yeast nutrient medium within suitable limits selectively inhibiting infection without inhibiting yeast growth materially. Various details of procedure are described. Cf. *C. A.* **24**, 461.

Purifying yeast after use for fermentation. GUSTAVE T. REICH. U. S. 1,783,521, Dec. 2. Yeast which has become contaminated by use in the fermentation of materials such as black strap molasses is dild. and sepd. by sedimentation into an upper portion contg. yeast of higher protein value and a lower portion contg. yeast of lower protein value together with impurities resulting from the previous use of the yeast, and these portions are separately collected and dehydrated, and may be used in *feed for animals*. An arrangement of app. is described.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Some of the uses of normal saline solution infusion in canine practice. H. CALVIN REA. *J. Am. Vet. Med. Assoc.* **30**, 612–6(1930).—NaCl soln., 0.9%, is a valuable therapeutic agent in canine practice. RACHEL BROWN

Experiments on magnesium sulfate as a general anesthetic. O. W. JOHNSON. *J. Am. Vet. Med. Assoc.* **30**, 644–5(1930).—$MgSO_4$, 20%, is a general anesthetic for small animals. RACHEL BROWN

Examination of cascara tablets. W. F. WOUTMAN. *Pharm. Weekblad* **67**, 1230–3 (1930).—Report of a more or less superficial examn. of 15 samples. A. W. DOX

So-called skin function oils and other nostrums. W. PEYER, H. IFFINGER AND C. BLINDOW. *Apoth. Ztg.* **45**, 1493–4(1930).—Of the many so-called skin function oils on the market some 12 different prepns. have been examd. with respect to their constituents and phys. properties, the results being presented in tabulated form. W. O. E.

Evaluation of sodium nitrite via D.A.-B. G. FRERICHS. *Apoth. Ztg.* **45**, 1507–8 (1930).—A crit. commentary of the official Ger. method, with suggestions for its improvement. W. O. E.

Estimation of arsenic in drug mixtures. G. WEISSMANN AND S. BABITSCH. *Pharm. Zentralhalle* **71**, 721–4(1930).—Of 6 different procedures examd. for estg. As in drug mixts., that of Andrews and Farr was found best suited to the purpose in question, provided certain modifications are introduced, as the use of a hypophosphite as reducing agent following the addn. of perhydrol. W. O. E.

Reactions of g- and k-strophanthin. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 724–5 (1930).—On adding 1 drop of H_2O and 3 drops of concd. H_2SO_4 to 0.005 g. of g-strophanthin, the mixt. becomes brick-red, gradually fading to green on warming. Under like treatment, k-strophanthin develops a brownish to olive-green and finally brown color. With a mixt. of 1 drop of 1% alc. furfural and 1 drop of concd. H_2SO_4, the g-glucoside develops a brownish, the k-glucoside a deep indigo-blue color. W. O. E.

Evaluation of liquor aluminii acetico-tartarici D.A.-B.6. RICHARD HOLDERMAN. *Pharm. Ztg.* **75**, 1331–2(1930).—Weigh exactly 1 g. of the sample, add 1 cc. AcOH and 100 cc. H_2O, then warm in a beaker to 60–65°. Now treat with about 50–60 cc. of hydroxyquinoline acetate soln., or until this reagent is in excess, then heat to boiling and add 3–5 g. NaOAc in 15 cc. H_2O. After 2–3 min. filter through a Gooch crucible, washing the ppt. first with hot H_2O and then with cold H_2O until the filtrate runs colorless. Dry at 105–10° to const. weight. Calcns. are given on the results obtained with controls indicating the amt. of Al acetotartrate should correspond to about 55% with the above method. W. O. E.

Glucosides of digitalis lanata Ehrh. C. MANNICH, PAUL MOHS AND W. MAUSS. *Arch. Pharm.* **268**, 453–76(1930).—Recent investigations of this species show it contains 4 active glucosides, characterized as lanadigin (lanata glucoside I), lanata glucoside II, lanata glucoside III (digitalinum verum) and lanata glucoside IV. Lanadigin forms colorless needles or prisms of the probable compn. $C_{41}H_{66}O_{17} + 4H_2O$, difficultly sol. in $CHCl_3$ and H_2O, yielding the digitoxose reaction of Keller-Kiliani. Heated quickly it m. 245°, $[\alpha]_D^{20}$ 33.3°. Hydrolytic scission with alc. HCl gives *lanadigigenin*, $C_{23}H_{34}O_5$, isomeric with gitoxigenin, probably identical with digoxigenin of Sidney Smith. Lanata

glucoside II appears to represent a mol. compd. of lanadigin with a 2nd glucoside, which yields the scission product digitoxigenin. The 3rd glucoside from *Digitalis lanata* appears to be identical with digitalinum verum of Kiliani. Lanata glucoside IV crystalizes in needles m. above 225°, $[\alpha]_D^{20}$ 5.50°. The relatively difficult scission with alc. HCl yields an optically inactive genin. The physiol. action is considerably less than that of the other 3 glucosides. W. O. E.

Radix saponariae. E. Gilg and P. N. Schürhoff. *Arch. Pharm.* **268,** 476–85 (1930).—The present study is essentially botanical. W. O. E.

Examination of essential oils. Kurt Bodendorf. *Arch. Pharm.* **268,** 486–91 (1930).—For purposes of characterization, some 15 different essential oils have been examd. as follows: Dissolve 0.6 to 0.8 g. of the sample in 25 cc. benzoic peroxide-$CHCl_3$ mixt. (so adjusted that 1 cc. = about 10 cc. 0.1 *N* $Na_2S_2O_3$); after 18 and 24 hrs. withdraw 5 cc. for admixt. with acidified KI soln., and titration (after 0.5 hr.) with 0.1 *N* $Na_2S_2O_3$. No considerable difference should exist between the values obtained in the 2 titrations. For calcg. the O no. the last value obtained should be used. W. O. E.

Abnormalities in perbenzoic acid oxidations. Kurt Bodendorf. *Arch. Pharm.* **268,** 491–9(1930).— In the investigation of a series of essential oils it developed that α,β-unsatd aldehydes could only with great difficulty be oxidized with perbenzoic peroxide, *i. e.*, cinnamic aldehyde is only attacked very slowly, while the oxidation of cinnamic ale proceeds quite normally. Cinnamic acid and its esters (Me, Et, Pr, iso-Pr and Bu) are, according to Boeseken, barely affected by perbenzoic acid. The same is likewise true of crotonic aldehyde. With α,β-unsatd. ketones the reactivity of the peracid is not entirely inhibited but markedly limited. BzCH:CHAc reacts very slowly with perbenzoic acid; dimethylpyrone does not react at all. In general, the reactivity of ethylene bonds toward the peracid (whether carboxyl, ester, aldehyde or ketone groups) is either markedly curtailed or entirely annulled. W. O. E.

New methods for the colorimetric estimation of alkaloids. C. A. Rojahn and Rudolf Seifert. *Arch. Pharm.* **268,** 499–520(1930).— An attempt has been made so to effect alkaloidal detns., that by means of a general precipitant the alkaloid can be isolated and its amt. detd. colorimetrically. Thus, with picric acid, 4 of the alkaloids studied, strychnine, quinine, emetine and cinchonine, were detd. In this connection NH_4 picrate only is used as the colorimetric indicator. The above 4 alkaloids may also be detd. by the use of silicotungstic acid and phosphotungstic acid. For evaluating the W component use is made of its reduction to tungsten blue. With Mayer's reagent only strychnine and emetine of the 4 named alkaloids could be detd. This reagent is thereupon evaluated by pptn. of the Hg as colloidal sulfide. Expts. with Dragendorff's reagent were unsuccessful. H ferrocyanide can be used in detg. strychnine, the ferrocyanide component being detd. in a limited way by the Cu ferrocyanide test, as also by the Prussian blue reaction. From the standpoint of accuracy, it appears that the colorimetric method is in many cases superior to the gravimetric. The utility of the colorimetric method increases as the amt. of alkaloid decreases. With larger amts. of alkaloid available, the gravimetric method is to be preferred. W. O. E.

Alkaloid-glucoside found in Solanum aviculare. Alfred A. Levi. *J. Soc. Chem. Ind.* **49,** 395–6T(1930).— The common New Zealand shrub known as the "bulli bulli" (Maori, "Purapura," *Solanum aviculare*) has a reputation among the local population for being poisonous, although the ripe berries were used by the early colonists for making jam. An examn. of the plant led to the isolation of a glucoside-alkaloidal substance from the green berries and in smaller proportion from the leaves. In its general properties it resembles ordinary solanine from potatoes, but its behavior on hydrolysis with acids proves conclusively that it is not identical with solanine. The name *purapurine* is suggested for the substance (chloroplatinate, chromate, iodide and bromide, for the most part too unstable for analysis); persistent boiling with HCl yields *purapuridine*, and apparently a hexose. W. O. E.

Examination of castor oil. Walter Meyer. *Suddeutsche Apoth.-Ztg.* **70,** 586 (1930).—An unusual sample of alleged Oleum ricini D.A.-B.6 is described which failed to give all the prescribed tests for an official product. In examg. this commodity special attention should be given its behavior on cooling to 0°, especially on the appearance of cryst. flakes after rubbing with a glass rod, and finally on further cooling whether a buttery opaque mass results. On shaking the sample with a like vol. of H_2O, no acid reaction should be perceptible. W. O. E.

Iron medication. Conrad Stich. *Suddeutsche Apoth.-Ztg.* **70,** 592–3(1930). A brief account of certain ancient devices for the prepn. and administration of Fe compds (as developed by impaling fruit with iron nails, digestion of nails in wine, etc.). W. O. E.

Germicidal powers and capillary activities of certain pure constituents of essential oils. ERIC K. RIDEAL, A. SCIVER AND N. E. G. RICHARDSON. *Perfumery Essential Oil Record* **21**, 341-4(1930).—As in many cases the essential oils examd. contain besides the one or more active ingredients, certain substances somewhat variable in amt. and of unknown compn., it was thought desirable to carry on the investigation with some of the pure constituents of essential oils, deferring to a later date the investigation of the causes of the exceptions noted. Accordingly, detn. of the Rideal-Walker PhOH coeffs. of the pure constituents has been effected, after converting them into soap emulsions. The data thereby obtained are reported in the present paper. W. O. E.

Reactions of thiophene. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 625-6(1930).—Certain color tests for thiophene are reviewed, and the behavior of uric acid toward thiophene-contg. C_6H_6, as noted by Denigès, made the basis for a reversible test. On adding to 0.01 g. alloxan 5 drops of concd. H_2SO_4 and then 1 drop of thiophene soln. (1 drop thiophene in 10 cc. abs. alc.), a blue color develops. On adding 2 drops thiophene soln. to 0.01 g. alloxan in 5 drops of H_2O, then following with 1 cc. cond. H_2SO_4, a blue color results. Variations of this procedure are also described, likewise the behavior of thiophene toward CH_2O, p-$(Me)_2C_6H_3CHO$, and β-naphthol in the presence of concd. H_2SO_4. W. O. E.

Reactions of antifebrin and phenacetin. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 626-8(1930); cf. *C. A.* **24**, 3081. A description of the various color changes obtained after hydrolyzing antifebrin and phenacetin with HCl, coupling with α- and β-naphthol, resp., and oxidizing with chloramine or bleaching powder. W. O. E.

Contraction of spirit denatured with acetic acid. HEINRICH KREIPE. *Deutsche Essigind.* **34**, 392-5(1930). The phenomenon (contraction) observed in diluting 96% (by vol.) spirit with H_2O (or 1% AcOH) to about 40% strength is discussed, and the exptl. results obtained are compared with Hayck's contraction tables. W. O. E.

Reactions of homatropine and novatropine. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 642(1930). See *C. A.* **24**, 5051. W. O. E.

Microchemical localization of phloroglucinol and its derivatives in plant material and drugs. ANNELIESE NIETHAMMER. *Pharm. Zentralhalle* **71**, 673-5(1930).—N. shows how the tests specified by Mohsel. (vanillin HCl and $(NH_2)_2C_6H_3CHO$-H_2SO_4) can be successfully used in the identification of phloroglucinol, if, in addn., resort is had to sublimation of a small piece of the material in a Klein-Werner app. under reduced pressure, the glucosidic substance being present in such cases as phloroglucotannoid. W. O. E.

Color reactions of anesthesine. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 677 (1930). The various color changes resulting from treatment of anesthesine with such reagents as HNO_3 + β-naphthol (or α-naphthol), resorcinol, $Ca(OCl)_2$ + NH_3, chloramine + PhOH, etc., are discussed. W. O. E.

Color reactions of cinchophen and neocinchophen. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 678(1930).—On the addn. of a few drops of fuming HCl to 0.01–0.02 g. cinchophen or neocinchophen, a blood-red or dichromate-red results. If the mixt. is then made alk. with NaOH soln. the colorless liquid remains clear with cinchophen, while with neocinchophen the likewise colorless liquid becomes clouded, later becoming clear. The former is sol. in NaOH soln. while neocinchophen at first remains undissolved. Milky cloudiness also develops on the addn. of 0.5 cc. fuming HCl to a few cg. of neocinchophen in 0.5 cc. strong EtOH, followed by NaOH soln. W. O. E.

Etrat, a new type of drug. H. ESCHENBRENNER. *Pharm. Ztg.* **75**, 1215(1930).—Etrates are non-hygroscopic, medium granulated (without the dust of crude drugs) prepns. possessing both taste and color of the parent drug. The prepn. involves extn. of the crude drug with a variety of solvents, the resulting exts. being united and dried under special precautions to avoid decompn., then redistributed over and in the exhausted marc as vehicle. W. O. E.

Etrat, a new highly active type of drug. CLEMENS GRIMME. *Pharm. Zentralhalle* **71**, 685-9(1930); cf. preceding abstr. W. O. E.

Phillyrin. FINN KOLLE AND TRYGVE HJERLOW. *Pharm. Zentralhalle* **71**, 705-8 (1930). Because of certain discrepancies in the data reported by Bertagnini and Eykman on the glucoside phillyrin, K. and H. have undertaken anew the examn. of this substance. Phyllyrin is an α glucoside possessing d-rotation, yielding on scission with α-glycosidase and rhamnodiastase (not however with emulsin) glucose and cryst. phillygenin. On hydrolysis with dil. acids in alc. soln. a cryst. aglucone and α-ethylglucoside resulted, which latter on further action of dil. acids yielded β-glucose and EtOH. W. O. E.

Reactions of salicylic acid and salol. LAD. EKKERT. *Pharm. Zentralhalle* **71**, 744

(1930).—On mixing 0.01 to 0.02 g. salicylic acid and 0.002 g. $NaNO_2$ with 0.5 cc. H_2O, followed by underlaying with 1 cc. concd. H_2SO_4, a red ring develops at the zone of contact and on shaking the mixt. becomes blood-red. Diln. with H_2O causes no change in color, while diln. with NaOH soln. produces a grass-green color. Na salicylate, Bi salicylate, secondary Hg salicylate, and acetylsalicylic acid behave like the free acid. Like treatment of salol leads to the red color of salicylic acid and the green of PhOH. W. O. E.

Ergot question. BERTA SAIKO-PITTNER. *Pharm. Monatsh.* **11**, 245–7(1930).—An address dealing essentially with products occurring in ergot and their probable specific effect on the animal economy. W. O. E.

Organization of the international union for furthering production and utilization of drug, spice and related plants. W. HIMMELBAUR. *Pharm. Monatsh.* **11**, 247–8 (1930).—A report. W. O. E.

Estimation of potassium guaiacolsulfonate in sirups. W. SCHÖBEL. *Pharm Ztg.* **75**, 1232–3(1930).—A commentary on the official Ger. method, as also on various procedures suggested by other workers, in connection with an outline of 2 methods based on the detn. of the sulfonic group. W. O. E.

Simplification of the method for estimating morphine in opium by use of the centrifuge. CONRAD STICH. *Pharm. Ztg.* **75**, 1233–4(1930).—The method described is essentially that given in the Swiss. Pharm. W. O. E.

Ammonia liniments and sapo kalinus. O. SCHMATOLLA. *Pharm. Ztg.* **75**, 1234 (1930).—The tendency in certain quarters to use indifferent oils (poppy, castor, etc.) in the prepn. of this liniment is criticized. To evaluate the product, weigh into a small cylinder graduated in 0.1–0.2 cc. 10 g. of the sample, add about 6–7 cc. dil. HCl and exactly 5 cc. C_6H_6 or benzine, close with a cork stopper and shake vigorously. After standing a short time the oily layer should amount to 13.5–13.6 cc W. O. E.

Examination of Spiritus saponatus. STOLDT. *Pharm. Ztg.* **75**, 1234(1930).—A com. sample had d. 0.9287, dry residue 15.46%, free alkali 1.7%, as compared with d 0.9265, dry residue 12.12%, free alkali 0.0%. W. O. E

Diacolation of condurango bark. H. BREDDIN. *Pharm. Ztg.* **75**, 1261–2(1930) Diacolation is the term applied to a special type of percolation in series or battery form In the present instance B. employs 3 tubes 65 cm. long and 3.5 cm. inner diam The method of treating the several charges is described in detail, as also the results thereby obtained. W. O. E.

Scientific pharmacy. XVI. Sterility of injection solutions. RAPP. *Pharm Ztg.* **75**, 1288–91(1930); cf. *C. A.* **24**, 4897.—A second instalment of an article discussing the question of sterility of injection solns., inclusive of app. used in effecting suitable sterilization and data obtained in the examn. of a series of solns. designed for injection W. O. E.

Rationalization of salve containers. I. G. OBERHARD. *Pharm. Ztg* **75**, 1301 (1930).—Certain suggestions are offered relative to types of containers (illustrated) best suited to contain salves. W. O. E

Faex medicinalis. ERNST RICHTER. *Apoth. Ztg.* **45**, 1447(1930).—The evaluation of medicinal yeast with respect to catalase may be improved as follows: Triturate 0.1 g of the sample with 2.4 g. powd. sugar. Overlay 0.1 g. of this mixt. on a soln. of 0.1 g benzidine in 1 cc. AcOH + 10 cc. 3% H_2O_2. The sugar dissolves and after 10 sec. there appears on the surface of the liquid a light blue foamy wreath when examd. in reflected light and against a white background. Dissolve the benzidine in the AcOH by gentle heating, cool and add the H_2O_2 very slowly so that only traces of the base are pptd. W. O. E

Fabrication of tablets. RAPP. *Süddeutsche Apoth. Ztg.* **70**, 631 3(1930).—A discussion of certain manipulations incident to tablet manuf., inclusive of certain formulas W. O. E

Diacolation of extraction aurantii fluidum. H. BREDDIN. *Pharm. Ztg.* **75**, 1320–1 (1930).—The article discusses all essential manipulations necessary to prepg. this ext by use of a series of tubes with their resp. charges and percolates. W. O. E.

Evaluation of liquor aluminii acetici D.A.-B.6. RICHARD HOLDERMANN. *Pharm. Ztg.* **75**, 1332(1930).—The procedure followed is identical with that previously described (hydroxyquinoline method for Al acetotartrate) with the exception that instead of 1 g of the sample 2 g. is taken. The amt. of Al hydroxyquinoline ppt. obtained should correspond to about 7.5% basic Al acetate. W. O. E.

Determination of quinine in dragée and in ampoules. EM. J. EMMANUEL. *Z. anal. Chem.* **82**, 296–7(1930).—Of *dragée*, place 2 or 3 pieces in a funnel, and dissolve away any paraffin by washing 3 times with 10 cc. portions of petr. ether. Evap. to

dryness in a weighed dish, dry at 80° and weigh the residual paraffin. Dry the residual pellets, pulverize in a mortar and digest at 50–60° with 50 cc. of 1% HCl, added gradually. Transfer to a separatory funnel and wash out with 1% HCl. To the soln. add 20 cc. of 10% NaOH and ext. the liberated quinine 3 times with 20% $CHCl_3$. Evap. the $CHCl_3$ soln. on the water bath and dry at 100° (preferably *in vacuo*) to const. wt. A dragée of 0.2 g. should contain not less than 0.163 g. of quinine monohydrochloride, 0.146 g. of the bihydrochloride or 0.118 g. of quinine bisulfate. To det. the quinine hydrochloride content of small *ampoules*, wash out the contents of one of these vials into the separatory funnel and treat as with 3 cc. of 10% NaOH and then with $CHCl_3$ as above. An ampoule of 0.4 g. should contain not less than 0.32 g. of the quinine salt. W. T. H.

The use of iron salts in the identification of morphine. LUIS ROSSI. *Ann. farm. bioquim.* **1**, 106–10(1930).—The bluish coloration given by morphine and its salts in the presence of $FeCl_2$ is due to the Fe ion. Concd. solns. of Fe alum (NH_3 and K) are the most suitable reagents because of their stability. When possible, the solid salts may be used in the presence of $BaSO_4$. B. S. LEVINE

The acidity of aromatic waters. E. CONDUCHÉ AND F. GRÉGOIRE. *Bull. sci. pharmacol.* **37**, 529–37(1930).— The value of orange flower water is higher, the larger the difference between the acidity before and after filtration. Fresh distillates have a p_H 5.8, aging changes it toward 7. This is caused by the action of air and of fungi. A. E. MEYER

The anatomical study of the root of Platycodon grandiflorum and Adenophora arten. T. MUNESADA AND S. KAWAKAMI. *J. Pharm. Soc. Japan* **50**, 945–50(1930). F. I. NAKAMURA

The pharmacognostical study of cod-liver oil of Japanese Dorsches ("Tara"). VII, VIII and IX. K. KAWAI. *J. Pharm. Soc. Japan* **50**, 951–98(1930); cf. *C. A.* **24**, 5427. F. I. NAKAMURA

Oil of lavender in pharmacy. R. NAVES. *Parfums de France* **8**, 259–72(1930) (in French and English).—A review of the therapeutic properties of oil of lavender, and of the analytical consts. prescribed by the principal pharmacopeas, which are critically discussed. A. PAPINEAU-COUTURE

The origin of pharmacy. Historical review of the development of the art of preparing pharmaceuticals and preparations resembling pharmaceutical compounds. G. B. INVERNI. *Giorn. farm. chim.* **79**, 356–8, 361–2, 365–70, 373–80, 383–8, 391–2, 395–6(1930). G. SCHWOCH

Utilization of by-products from saccharin manufacture (HERZOG) **27.** Apparatus or processing oils, salves, confections, etc. (U. S. pat. 1,783,864–5–6–7) **1.**

Pharmaceutical preparations. I. G. FARBENIND. A.-G. Ger. 504,681, Oct. 7, 1927. Therapeutically active prepns. are formed by combining alkaloid bases with hydroxylated diaryl ketone-carboxylic acids. Thus, 2-(4'-hydroxybenzoyl)benzoic acid is combined with 3-phenyldehydroquinazoline to give a product m. 187–90°. Other examples described the combination of hydroxy- or dihydroxybenzoylbenzoic acid with such alkaloid bases as ephedrine, yohimbine, morphine, novocaine and hydrastinine.

Synthetic drugs. KNOLL A.-G. CHEM. FAB., GUSTAV HILDEBRANDT and ERWIN LEUBE. Ger. 506,279, Nov. 30, 1926. The amide and ureide of α-bromo-β,β-diethylpropionic acid are prepd. from the acid or its anhydride or halides by the customary methods. Examples are given. The amide m. 79–80°; the ureide m. 139°. They have *sedative properties.*

Synthetic drugs. SCHERING-KAHLBAUM A.-G. (Walter Schoeller, Erich Borgwardt, and Hans G. Allardt, inventors). Ger. 506,443, Mar. 3, 1925. Auromercapto acids are prepd. by the action of auric salts on org. mercapto acids in the presence of SO_2. Thus, 4-amino-2-mercaptobenzenecarboxylic acid, treated in HCl soln. with H_2SO_3 and $KAuBr_4$, yields 4-amino-2-auromercaptobenzenecarboxylic acid. Cf. *C. A.* **24**, 2241.

Medicinal liquid-petrolatum-agar-water emulsion. LEON A. WILSON (one-half to Edwin L. Yewell). U. S. 1,784,324, Dec. 9. In prepg. the emulsion, water and agar are boiled together, mixed with mineral oil and the mixt. is agitated until cool.

Antiseptic liquids. G. PANSINI. Brit. 332,520, Jan. 17, 1929. An aq. soln. of NaOCl or other alkali metal hypochlorite is satd. with O_3 produced electrolytically. Various details of app. and procedure are described.

Permanently sterilized and stable sero-vaccines. GEORG MAYER. Ger. 505,707, Apr. 3, 1927. Young cultures, *e. g.*, of *Staphylococcus* and serum products, *e. g.*, pleural exudation, are shaken together and treated with ultra-violet light in closed quartz vessels. The autolysis of the product is suspended for a period according to the length of treatment with the ultra-violet light.

Diacetyl-3,3'-diamino-4,4'-dihydroxy-5,5'-diiodoarsenobenzene. ALEXANDER D. MACALLUM. U. S. 1,782,432, Nov. 25. This compd. is made by the reaction of Na hyposulfite at 55-60°, in an inert atm., on acetyl-3-amino-4-hydroxy-5-iodophenylarsonic acid and is a lemon-yellow solid, sol. in acetone, PhOH, benzaldehyde and pyridine, and suitable for use as a *trypanocide*.

Acetyl-*k*-strophanthidin. SCHERING-KAHLBAUM A.-G. (Wilhelm Neumann, inventor). Ger. 506,045, April 6, 1928. See Brit. 323,973 (*C. A.* **24**, 3249).

Bismuth hydroxide. I. G. FARBENIND. A.-G. Brit. 332,504, Dec. 3, 1928. An aq. soln. of a Bi salt is pptd. by an alkali such as NH_3, and adherent water is removed from the ppt. after filtration by first washing with a solvent which is more volatile than and sol. in water (such as EtOH, MeOH or acetone) and then washing with a second volatile solvent (such as EtCl, ether or $CHCl_3$) and then evapg. the residue of the second solvent. A product is obtained which is suitable for use, when suspended in oil, in the treatment of syphilis.

Mercury compound of *m*-cresol, etc. DUNCAN M. COPLEY and JOHN P. SNYDER (to Norwich Pharmacal Co.). U. S 1,782,090, Nov. 18. Various details are given of the prepn. of an antiseptic and germicidal compn. consisting of the hydroxymercuri substitution product of a mixt. of a plurality of cresol isomers one of which is *m*-cresol, with $HgCl_2$, the product being a cream-white powder, substantially odorless, insol in water, alc. and cold dil. HCl or cold dil. HNO_3, but readily sol. in dil. KOH or NaOH solns, free from inorg chlorides and having a bacteriostatic potency twice that of $HgCl_2$ in equal ratios of diln. The product contains the inner anhydride of hydroxymercuri-*m*-cresol and chloromercuri-anhydrohydroxymercur-*m*-cresol.

Menthols. SCHERING-KAHLBAUM A.-G. (Walter Schoeller, Hans Jordan and Reinhard Clerc, inventors). Ger. 506,044, Aug. 17, 1926. See Brit. 276,010 (*C. A.* **22**, 2379).

Infra-red element for therapeutic lamps and holders. ERNEST SUTER and JULIUS NUETZI. U. S. 1,782,218, Nov. 18. An insulating core with a spiral groove carries a coiled resistance wire extending into the groove and a screen coating for the wire consisting of "aloxide," neutral magnetic Fe oxide black, "silicon soda" and "red phosphor Zn oxide."

Disinfectants. CORNELIUS KELETI. Ger. 504,603, Aug. 7, 1926. A disinfecting, tanning or cosmetic prepn. is prepd. by leading halogen into a mixt. of aldehyde and soap. Halogenated oil may be used instead of halogen, and one or more salts of heavy metals may be added.

Cosmetics. CHEM. FAB. JOHANN A. WÜLFING. Ger. 499,251, Oct. 12, 1926. The high-mol. degradation products of keratinous materials are used as cosmetics, alone or with the customary addns. The degradation products may be prepd. by hydrolyzing keratinous materials with alkali until they have lost their structure, and pptg. the products with acid.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Nitric acid produced from ammonia by modified pressure system. GIACOMO FAUSER. *Chem. Met. Eng.* **37**, 604-8(1930).— The advantages of NH_3 oxidation under pressure are shown in theory and practice. The best conversion is at 850°, with 9.5% NH_3 content when air only is used. At any pressure there is an optimum velocity of mixt. for the best conversion. Conversion was 91% at 4 atm., *vs.* 95-96% at atm. pressure. Under pressure a Pt gauze can oxidize more NH_3, but gain in the amt. of Pt used does not wholly justify the loss of NH_3 under pressure, which represents more than interest and amortization. The addnl. expense of Pt is compensated partly by saving in oxidizing equipment. Regeneration of Pt gauze is necessary after 6-7 months in atm. oxidation, but under pressure the period is shorter and cleaning more difficult. The presence of Fe is very harmful. To avoid difficulties due to resistance to flow and heat removal in absorption towers, an absorption system of horizontal spray tanks with external cooling is used. E. M. SYMMES

Dehydration of silicic acid by ignition. BERNHARD NEUMANN. *Z. angew. Chem.*

43, 882–3(1930).—On heating SiO_2 from 200° to 1000° the H_2O content falls from 6.6 to 0.0%, and simultaneously adsorption of the crystalloid dye diminishes. Adsorption of Au sol in xylene rises as the temp. of ignition rises. Abnormalities occur from 600° to 900°, because of the change of α-quartz to β-quartz at 575°, and β-quartz to β-tridymite at 870°. E. M. SYMMES

Commercial production of anhydrous aluminum chloride. C. WURSTER. *Z. angew. Chem.* **43**, 877–80(1930); cf. McAfee (*C. A.* **23**, 4301).—The literature is reviewed. Production of $AlCl_3$ from Al ores continuously, without external heat, is possible, heat of chlorination being sufficient. Shaft furnaces are used on the countercurrent principle, with tight Fe outside jackets and a lining of ceramic material stable to Cl and $AlCl_3$ at high temp. Between the 2 there is heat-insulating kieselguhr. CO and Cl are fed into the bottom, anhyd. clay or bauxite is fed continuously at the top, and a residue high in SiO_2 removed continuously from the bottom. $AlCl_3$ and CO_2 leave the top, passing to air- or H_2O-cooled cylinders having discharge devices. At first the contents are heated to about 500° by producer gas, then cold CO and Cl blown in. The internal temp. is kept at about 900°. Furnaces have operated continuously for years without relining, as compared to the 100 days given in the literature. After some time of operation, temp. in the lower part of the furnace drops, because cold gas meets material low in Al, giving poor extn. To avoid this, Cl is first converted to $COCl_2$, then led into the bottom of the furnace at 500°. If CO is unavailable, coal can be used in the bauxite briquets. The product contains $AlCl_3$ 97, $FeCl_3$ 2.5, $TiCl_4$ 0.5, yellow-brown, coarse crystals. E. M. SYMMES

Ammonium chloride. F. FREITAG. *Chem. Trade J.* **87**, 477–9(1930).—A review of modern mfg. methods, with especial attention to the difficulties of the direct process of uniting the gases, NH_3 and HCl, the modified NH_3-soda process, and the salt-sulfate methods. Analytical control and the various forms of sal-ammoniac are discussed. W. H. BOYNTON

Zinc meta-arsenite. C. MARSHALL TAYLOR. *Canadian Mining J.* **51**, 1121–3 (1930).—$Zn(AsO_2)_2$ is prepd. from Zn acetate and $HAsO_2$. It is very sparingly sol. in H_2O, but readily sol. in the body juices of any of the com. wood-destroying fungi. Its advantages as a wood preservative are: it is odorless, colorless, paintable, permanent and it burns less readily than untreated timber. A formula for timber costs (*Coal Age*, Nov., **1928**) is $A = \frac{PR(1+R)N}{(1+R)N-1}$, where A = annual charge including interest and amortization, P = rate of interest expressed decimally and N = life in years. The av. life untreated is 3 yrs.; treated 8–10 yrs., and permanent and semi-permanent timber destroyed by crush = 20%. W. H. BOYNTON

Esters of phosphoric acid as substitutes for camphor. A. BRESSER. *Industria chimica* **5**, 740–2(1930); cf. *C. A.* **24**, 1214.—A summary of some of the esters of phosphoric acid proposed and used as camphor substitutes. They are distinguished by being odorless, very stable, much less flammable and not discoloring in sunlight, *e. g.*, triphenyl, tricresyl, trinaphthyl phosphates, thiophosphates corresponding to $(PhO)_3PS$, phosphoric acid esters of di- and tetrachlorophenol, di- and tetrachlornaphthol, the corresponding Br_2, I_2, F compds., and tribenzylphosphate, $(PhCH_2)_3PO_4$. Patent references are given. A. W. CONTIERI

Evaluation of active carbons. E. BERL AND W. HERBERT. *Z. angew. Chem.* **43**, 904–8(1930).—Air-vapor satn., C_6H_6 heating, C_6H_5OH adsorption, molasses, $HgCl_2$ adsorption and methylene blue tests are investigated and criticized. A modification of the latter by altering the amt. of methylene blue so as to give a final concn. of 1 g. per l. is advocated for greater accuracy. The Duboscq colorimeter can give a 15% error with comparison columns varying by 2:1. E. M. SYMMES

Production of carbon black from propane. W. B. PLUMMER AND T. P. KELLER. *Ind. Eng. Chem.* **22**, 1209–11(1930).—C black as good as that made from CH_4 may be made from hydrocarbons as high as C_3H_8, but this may not be true for higher liquid hydrocarbons. The basic flame reactions are the same for CH_4 and C_3H_8. The function of the channels is mainly cooling, as shown by heating the same to 650°. There is a lower limit of desirable cooling of channels. Complete removal of the channels does not reduce the yields as much as expected, and produces a lower grade of C black. The type of C black made is not much affected by the surrounding atm., and is, therefore, detd. by the conditions within the flame. E. M. SYMMES

Carbon black, lampblack and bone black—their properties and industrial application. CHARLES H. BUTCHER. *Chem. Trade J.* **87**, 399–401(1930).—The manuf. of lampblack, of vegetable black, of carbon black or gas black and bone black are outlined

and means of distinguishing between lampblack and carbon black is mentioned. The detns. of moisture, hygroscopicity of carbon black, sp. gr., degree of fineness, bulking value, presence of oil and grease, and of grit are outlined. W. H. BOYNTON

Bromine and iodine. PAUL M. TYLER AND AMY B. CLINTON. Bur. Mines, *Information Circ.* 6387, 26 pp.(1930).—Description, uses, occurrence, methods of extn., history, world production, domestic production, imports, duties, foreign industry, markets and prices of Br and I are given. A 2 pp. bibliography and numerous footnote references are shown. ALDEN H. EMERY

Preparation of lanthanum from Swedish cerite. Separation of lanthanum-ammonium nitrate. Spectrographic analysis of lanthanum oxide obtained. R. LLORD Y GAMBOA. *Anales soc. españ. fís. quím.* 28, 1145–52(1930).—La_2O_3 was prepd. by calcining double La-NH_4 nitrate, obtained by long-continued fractional crystn. La_2O_3, Pr_2O_3 and Nd_2O_3 were prepd. from only 24-g. samples. The purity of the product was detd. by the spectroscope. E. M. SYMMES

Various processes for the extraction of magnesium from dolomite. LIVIO CAMBI. *Giorn. chim. ind. applicata* 12, 438–41(1930).—Methods of extn. of Mg from dolomites abundant in Italy are reviewed, particularly the method using HNO_3 and calcined dolomite. Electrometric titration with HNO_3 shows 2 breaks, $Ca(NO_3)_2$ forming first, then $Mg(NO_3)_2$, giving a method for fractional sepn. of these salts. The reactions take place readily at temps. above 50°. A sample whose original compn. was MgO 20.78, CaO 31.2, Al_2O_3 + Fe_2O_3 0.43, CO_2 46.82% was sepd. so that the product was MgO 98.91%, CaO 0.39%, Al_2O_3 + Fe_2O_3 trace. A serious problem is the recovery of HNO_3 from the calcination of the nitrates. A. W. CONTIERI

Producing sulfur at Newgulf. GEORGE H. REID. *Chem. Met. Eng.* 37, 668–72 (1930). E. H.

Diatomaceous earth. ROBERT CALVERT. *J. Chem. Education* 7, 2829–49(1930). E. H.

Armenian pumice stone. S. OTAROV. *Stroitelnuie Materialui* (*Building Materials*) No. 1, 69–70(1930).—The description and chem. compn. of large deposits of pumice stone in Russian Armenia are given. The quality of this pumice stone makes it suitable for *bricks, pumice cement* and *prepn. of green glass.* M. V. KONDOIDY

Color reaction of Japanese acid clay toward malachite green leuco base hydrochloride. NAOTO KAMEYAMA AND SHUMPEI OKA. *J. Soc. Chem. Ind. Japan* 33, Suppl. binding 335–6(1930); cf. *C. A.* 24, 1940.—The original clay beds contained pockets of brownish black material, previously found distributed through the clay, and which gave spotted color reactions. This contaminating material was impure pyrolusite. E. M. SYMMES

Gypsum and gypsum products. W. A. FELSING AND A. D. POTTER. *J. Chem. Education* 7, 2788–2807(1930). E. H.

Emulsions and suspensions of various kinds (Brit. pat. 332,533) 13.

Sulfuric acid. HUGO PETERSEN. U. S. 1,781,954, Nov. 18. Sulfurous acid gases to be oxidized are passed with nitrous vitriol of at least 55° Bé. strength, vertically through packed reaction spaces, the flowing resistance in which is so regulated as to correspond to a pressure ranging from 0.25 to 6.0 mm. water-column for each meter of vertical flow, and the nitrous strength of the vitriol at the bottom of the spaces is kept within a limit of at least a quarter of the nitrous strength at the top of the spaces. An arrangement of app. is described.

Colloidal silicic acid. ALEXANDER P. OKATOV. U. S. 1,783,304, Dec. 2. A process is described involving reaction of Na silicate with HCl treatment of the gel. with solns. of salts of polybasic acids together with NH_3. Cf. *C. A.* 24, 693.

Ammonia-air mixtures suitable for use in nitric acid manufacture. HARRY PAULING. U. S. 1,784,074, Dec. 9. An arrangement of app. is described for producing a uniform mixt. of NH_3 and air, comprising a liquid circulating system, an NH_3 absorber in the system, means for forcing an air current into the NH_3 soln., and automatic control devices for controlling the circulation of the liquid actuated by variations in sp. gr. of the soln.

Wax bottles suitable for holding hydrofluoric acid. DANIEL FAUERBACH (to General Chemical Co.). U. S. 1,784,686, Dec. 9. Various details of manuf. are described.

Separating acidic gases. ROBERT R. BOTTOMS (to Girdler Corp.). U. S. 1,783,901, Dec. 2. See Fr. 685,992 (*C. A.* 24, 5898).

Acid phosphate plant. INGENUIN HECHENBLEIKNER (to Chemical Construction Corp.). U. S. 1,782,821, Nov. 25. In an excavator plant, a den is provided for contg. material to be excavated, with a rotary cutter movable into and from the den and so designed that rotation of the cutter disk causes a suction of air from the outer face of the disk toward the operating face. Various details of construction are described.

Catalytic apparatus for ammonia synthesis or other exothermic reactions. O. PIETTE and UNION CHIMIQUE BELGE, SOC. ANON. Brit. 332,532, April 12, 1929. Various details are given of an app. with concentric tubes and an elec. resistance heater.

Treating ammoniacal liquors. DWIGHT R. MEANS (to Pittsburgh Plate Glass Co.). U. S. 1,781,987, Nov. 18. In recovery of NH_3 from liquor contg. fixed NH_4 compds. including NH_4Cl, unpulverized quicklime contg. some unburned limestone is supplied in quantity sufficient to decompose the fixed NH_4 compds., at one end of a mixing app., to which the liquor is supplied counter-currentwise; the quicklime and assocd. unburned limestone gradually work downwardly and is suspended in the liquor and the unburned limestone then settles and segregates in its lower portion and is removed; the liquor contg. the suspended lime is then subjected to distn. to obtain NH_3. App. is described.

Alkali cyanides. SYLVIAN COULIER. Ger. 504,535, Nov. 3, 1925. These are prepd. by treating the gases obtained by the dry distn. of nitrogenous materials in the presence of alkali compds. with carboniferous materials. The distn. residue may be used as the latter material. The distn. temp. should not exceed 500°. In examples, old leather, leather waste and tanning residues, or de-sugared molasses is used as the starting material.

Ferricyanides. JOSEF SCHRÖTER. (Wilhelm Gluud, Konrad Keller, Walter Klempt and Cläre Dieckmann, inventors). Ger. 504,501, July 6, 1928. Addn. to 502,883. Ferricyanides are prepd. by treating a ferrocyanide soln. with a weak acid, or with a mixt. of weak acid and a stream of O-contg. gas under pressure, and subjecting the resulting soln. to electrolytic oxidation. In an example, $Ca_2FeC_6N_6$ is heated to 100° in an autoclave at 50 atm. with a CO_2-air mixt. The electrolytic oxidation of the resulting soln. gives $Ca_3[Fe(CN)_6]_2$.

Alkali metal hydroxides. ERNST HEINZE (to I. G. Farbenind. A.-G.). U. S. 1,784,066, Dec. 9. An amalgam of alkali-forming metal is agitated with water by use of a stirrer composed of C material such as graphite or coke.

Double fluorides. I. G. FARBENIND. A.-G. Ger. 506,127, Mar. 29, 1925. Addn. to 443,007, 461,136 and 479,400 (*C. A.* **23**, 4782). In mfg. double compds. of AlF_3 and alkali fluorides as described in the prior patents mentioned, it is found that a small excess of F ions is permissible, without necessarily reducing Fe to the ferrous state, provided that free mineral acid is present. Examples are given.

Solutions of per-compounds. ÖSTERREICHISCHE CHEM. WERKE G. M. B. H. Austrian 119,036, Mar. 15, 1930. Solns. of peroxides, per-salts and per-acids, particularly bleaching solns., are stabilized by addn. of an alkali pyrophosphate together with an alkali chloride and (or) an alkali silicate. Thus, a 30% H_2O_2 soln. may be treated with $Na_4P_2O_7.10H_2O$ 2.5 and NaCl 1%, the usual acidity of the soln. being restored by addn. of H_2SO_4.

Metallic nitrates. FRIEDRICH A. HENGLEIN (to I. G. Farbenind. A.-G.). U. S. 1,783,647, Dec. 2. Nitrates are formed by the action of O upon nitrites such as those of K or Zn in the presence of water and an alkali metal hydroxide under superatm. pressure and at a temp. above 150°.

Chromium compounds. CHEM. FAB. GRÜNAU LANDSHOFF & MEYER A.-G. (Hans Fahnrich, inventor). Ger. 506,436, June 5, 1926. Alkali chromoxalates in which part of the oxalic acid residue is replaced by SO_4, and to which the formulas given below are assigned, are prepd. by the reaction of an alkali hydroxide, $Cr(OH)_3$, $(COOH)_2$, and H_2SO_4 in the mol. proportions corresponding to the formulas, and evapg. the soln. obtained. Like products are obtainable by substituting another polybasic org. acid for oxalic acid. Examples are given.

$$\left[\begin{matrix} C_2O_4 \\ CrSO_4 \\ (H_2O)_2 \end{matrix}\right] Na \qquad \left[\begin{matrix} (C_2O_4)_2 \\ CrSO_4 \end{matrix}\right] Na_3 \qquad \left[\begin{matrix} C_2O_4 \\ Cr(SO_4)_2 \end{matrix}\right] Na_3$$

Zinc compounds. METALLGES. A.-G. (Freiherr Conway von Girsewald, Hans Weidmann, and Erich Stahl, inventors). Ger. 506,343, Dec. 14, 1926. This relates to the recovery of Zn from the poor lyes obtained by roasting ores contg. Zn and Cu under chloridizing conditions, and extg. with water. The lyes are first freed from Cu by a method not involving the introduction of an addnl. metal into the lye, *e. g.*, by pptn. as CuCl, and are then cooled to sep. Na_2SO_4. The residual lye is used to ext. a further amt.

of roasted ore, and the process is repeated until, after sepg. Cu and Na_2SO_4, a lye rich in Zn is obtained, from which Zn is recovered as ZnS, basic $ZnSO_4$, etc.

Readily soluble stable hypochlorite. PAUL R. HERSHMAN (one-fourth each to C. O. Sethness, C. H. Sethness and Paul Rudnick). U. S. 1,784,286, Dec. 9. Ca hypochlorite is mixed with NaOAc in the presence of moisture, and the product is then dried. Cf. *C. A.* **24**, 209.

Deacidifying ammonium sulfate. KELLNER & FLOTHMANN G. M. B. H. Ger. 504,534, Apr. 24, 1927. The $(NH_4)_2SO_4$ soln. is passed down a tower in which perforated plates fixed to a central axis rotate, and is simultaneously subjected to the action of basic gas or vapor. The app. is described.

Refining antimonic lead sulfate. ALEXANDER STEWART (to C. L. Constant Co.). U. S. 1,783,986, Dec. 9. In the refining of antimonic Pb sulfate in a weak H_2SO_4 soln., hydrolysis of the Sb is prevented by maintaining the soln. at a sufficiently high concn. of SO_4 ions by addn. of a sulfate of an alkali metal.

Barium hydroxide. KALI-CHEMIE A.-G. (Fritz Rothe and Friedrich Rüsberg, inventors). Ger. 506,275, Aug. 10, 1926. $Ba(OH)_2$ is prepd. by decompg. Ba silicates with H_2O under pressure at a temp. above 100°. A large excess of water need not be used, so that solns. suitable for direct crystn. are obtained. Dil. solns. of $Ba(OH)_2$ may be used for the decompn. Examples are given. Cf. *C. A.* **24**, 5115.

Conversion of calcium nitrate or other salts into globular or similar shapes. BODO HAAK (to I. G. Farbenind. A.-G.). U. S. 1,782,038, Nov. 18. The fused salt is dropped into a cooled non-solvent liquid such as CCl_4 set into rotation about a vertical axis within the liquid. App. is described.

White anhydrous calcium sulfate. CHARLES B. DURGIN, ARTHUR B. GERBER and PAUL LOGUE (to Swann Research, Inc.). U. S. 1,783,417, Dec. 2. Ca phosphate is added to hydrated $CaSO_4$ and the mixt. is heated to about 760° to produce a product formed mainly of $CaSO_4$ (which may contain about 5% of Ca phosphate) suitable for *use in dentifrices*, etc.

Iron carbonyl. ALWIN MITTASCH and CARL MÜLLER (to I. G. Farbenind. A.-G.). U. S. 1,783,744, Dec. 2. Metallic iron with its surfaces free from oxide is treated with a gas contg. CO under a pressure not exceeding 50 atm. and at an elevated temp. and the gas is passed over the metal at such speed that the carbonyl formed is substantially carried away as formed. Cf. *C. A.* **24**, 3613.

Hydrogen peroxide. JAMES B. PIERCE, JR. (to Barium Reduction Corp.). U. S. 1,781,859, Nov. 18. SrO_2 is added to a soln. of a mixt. of acids such as H_2SO_4 and HCl, one of which forms a relatively insol. Sr salt and the other a relatively sol. Sr salt (the second-mentioned acid being present in small proportion).

Magnesium carbonate. VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Ger. 506,635, Oct. 24, 1925. Addn. to 505,304. The method of decompg $KHCO_3.MgCO_3.4H_2O$ with H_2O described in Ger. 505,304 (*C. A.* **24**, 5948) is modified in that the double salt is only partially decompd., by treatment with H_2O at a low temp., before the MgO or $Mg(OH)_2$ is added.

Magnesium chloride. I. G. FARBENIND. A.-G. (Wilhelm Moschel, inventor). Ger. 506,276, Oct. 5, 1928. See Fr. 682,303 (*C. A.* **24**, 4361).

Manganous phosphate. N. V. MAATSCHAPPIJ TOT EXPLOITATIE VAN DE PARKER OCTROOIEN "PARKER RUST PROOF." Ger. 504,568, Apr. 5, 1927. $Mn_3(PO_4)_2$ for the prepn. or regeneration of a rust-proofing bath is obtained by dissolving Fe-Mn in H_3PO_4 and oxidizing the resulting $Fe_3(PO_4)_2$ and $Mn_3(PO_4)_2$ soln. to ppt. $FePO_4$, the unchanged $Mn_3(PO_4)_2$ remaining in soln.

Disodium pyrophosphate. METALLGES. A.-G. (Freiherr Conway von Girsewald and Hans Weidmann, inventors). Ger. 506,435, May 18, 1929. A concd. soln. of H_3PO_4 is treated with the appropriate amt. of NaCl and evapd. *in vacuo* at a temp. rising to 180–200°, whereby the formation of insol. metaphosphate is avoided. An example is given.

Colloidal silver iodide. HARRY S. KEELAN (to E. R. Squibb and Sons). U. S. 1,783,334, Dec. 2. An insol. Ag salt such as AgCl in colloidal soln. is subjected to reaction with an iodide of an alkali-forming metal such as NaI.

Strontium oxide in flake form. JAMES B. PIERCE, JR. (to Barium Reduction Corp.). U. S. 1,782,830, Nov. 25. SrO in the form of flakes is obtained by heating pptd. $SrCO_3$ with ashless carbon black at 1200° in a closed muffle. The SrO is especially suitable for making SrO_2.

Titanium acid sulfate. FOORD VON BICHOWSKY (to Titania Corp.). U. S. 1,783,684, Dec. 2. By reaction under specified conditions between H_2SO_4 and Ti nitride or cyanonitride with slow addn. of HNO_3, and evapn. of the filtered soln., a semi-solid

product is obtained of the formula $H_2SO_4.Ti(SO_4)_2.4H_2O$ which reacts with K_2SO_4 in aq. soln. to form a white powder of the formula $4K_2SO_4.5TiOSO_4.2TiO_2$. By use of $NaNO_3$ instead of HNO_3, there is obtained a product of the approx. compn. $NaHSO_4.Ti(SO_4)_2.18H_2O$. The acid sulfates of Ti can replace Al sulfate for the *treatment of water or sewage* or for use as a *mordant*, can be used in *paper manuf.*, as a *desiccating agent* in chem. laboratories or for *drying gases*, or as a source for producing other Ti compds. by electric reduction or other methods.

Zinc oxide. FREDERIC E. PIERCE. U. S. 1,781,702, Nov. 18. A Zn-bearing ore is smelted in a reducing atm. in a reverberatory furnace in the presence of C and such other substances as will form a slag with the ore impurities, and the Zn vapor produced is led into a combustion chamber and treated with air to effect oxidation and cooling, and the ZnO is sepd. from other gaseous products. App. is described.

Catalytic converter apparatus suitable for oxidizing sulfur dioxide. INGENUIN HECHENBLEIKNER (to Chemical Construction Corp.). U. S. 1,782,824, Nov. 25. Converters connected in cascade are provided with an interposed cooler for the gases, the operation of which is controlled by the temp. in the first converter. Various structural details are described.

Mechanical furnace for making alkali sulfate from alkali chloride and sulfuric acid. KARL EHRENFRIED. Ger. 506,348, Aug. 22, 1926.

Hydrogen. C. F. R. HARRISON and IMPERIAL CHEMICAL INDUSTRIES, LTD. Brit. 332,571, April 19, 1929. In a cyclic process carbonaceous material such as coke is first heated to about 1500° by blowing with air, and CH_4 or similar hydrocarbon is then blown in until the temp. falls to about 1100° with production of H and C, and finally steam is blown in until the temp. falls to about 900° with production of water gas from which a further quantity of H may be obtained by catalysis with steam; the steps are then repeated, and the process may be carried on in conjunction with the destructive hydrogenation of coal or the like by which large quantities of CH_4 are produced. An app. is described.

Hydrogen. I. G. FARBENIND. A.-G. (Hans Bähr, inventor). Ger. 506,041, May 4, 1929. In the manuf. of H or gas mixts. contg. H by alternately oxidizing a metal, *e. g.*, Fe, with steam, with or without air, and reducing the oxide, sintering of the mass during the reduction stage is prevented by effecting the reduction with powd. or granular carbonaceous material in conjunction with indifferent or reducing gases. Preferably, the mass is kept in motion in both the reduction and oxidation stages, *e. g.*, by blowing the gases through the mass so that the latter is whirled about, or by the use of rotary tube furnaces, shaft ovens or the like. Suitable addns. may be made to the mass in order to obtain useful by-products. Thus, if CaO is added to a mixt. of Fe ore and powd. coal, there is obtained after reduction a mixt. of Fe with a product which can be worked up into *cement;* the mixt. may be sepd. magnetically or by winnowing.

Hydrogen. FREDERICK T. SNYDER. U. S. 1,781,935, Nov. 18. A hydrocarbon gas such as natural gas or gas from coal or oil is passed in contact with refractory material of increasing temp. with exclusion of air, the max. temp. of the material being above the decompn. temp. of the gas, and then through material of decreasing temp. Decompn. with C deposition is effected near the material of max. temp., and the deposited C is subsequently burned with heated air to re-heat the material, and part of the heat of the products of combustion is absorbed in the part of the refractory material with which the gas comes initially into contact. App. is described.

Rectification system for obtaining hydrogen from gas mixtures by partial liquefaction. GEORGES CLAUDE (to Société l'air liquide (Soc. anon. pour l'étude et l'exploitation des procédés Georges Claude)). U. S. 1,782,287, Nov. 18. App. and various details of operation are described.

Rhenium. SIEMENS & HALSKE A.-G. Brit. 332,627, Nov. 22, 1928. In extg. rhenium from minerals such as columbite, gadolinite or magnetic pyrites, HCl or H_2SO_4 may be used as a solvent and the rhenium then pptd. as sulfide as with H_2S (together with other sulfides so pptd.). The sulfide ppt. may be redissolved in HNO_3, followed by pptn. of constituents other than rhenium with NH_4NO_3 and H_3PO_4 or a phosphate, and repptn. with H_2S, with a final fractional sublimation, reduction by H, heating in O, reduction, fractional volatilization, and reoxidation of the sublimates repeatedly to sep. the rhenium. Fractional sublimation of mixed chlorides also is mentioned.

Sulfur. I. G. FARBENIND. A.-G. (Paul Koppe and Günther Robbel, inventors). Ger. 506,042, Mar. 27, 1929. See Fr. 681,629 (*C. A.* **24**, 4362).

Sulfur recovery from alkali metal polysulfide solutions. HELLMUTH LANGHEINRICH (to I. G. Farbenind. A.-G.). U. S. 1,783,725, Dec. 2. See Ger. 495,182 (*C. A.* 24, 3331).

Sulfur from pyrites. RAYMOND F. BACON. U. S. 1,782,225, Nov. 18. Fe pyrites is heated to 600–700° in a rotary retort and treated with steam at about this same temp. and the hot gaseous product (contg. S and H_2S) is treated with SO_2 at 600–700° and the elemental S thus formed is condensed, without substantial condensation of the steam, the exhaust gases of the condensing operation are reheated by heat from the hot gases leaving the retort, further heated to 600–700° by excess heat from the retort heating device, and the reheated gases are reintroduced into the retort for further reaction with Fe pyrites. Cf. following abstr. and *C. A.* **24**, 4596.

Sulfur from iron pyrites. RAYMOND F. BACON. U. S. 1,782,226, Nov. 18. A partial elimination of S from iron pyrites is effected by treatment with steam at an elevated temp. (suitably about 600–700°), thus forming a gaseous product contg. S and H_2S, and a further removal of S from the residual Fe sulfide of the pyrites is then effected by oxidation at an elevated temp. (suitably by the action of air) to produce a gas contg. SO_2; these 2 gaseous products are then caused to react with each other and the S formed is condensed. Cf. preceding abstr. and *C. A.* **24**, 4596.

Mold for casting sulfur. WILHELM VON DIETERICH (to Rhenania-Kunheim Verein Chemischen Fabriken A.-G.). U. S. 1,784,769, Dec. 9. A tubular mold of metal such as Al is provided with a longitudinal expansion slit and with a device for normally holding the slit closed.

Active carbon. ALGEMEENE NORIT MAATSCHAPPIJ. Ger. 504,636, April 24, 1925. Active C with a high adsorptive capacity is formed in granular or molded form by mixing activated C with inorg. adsorptive agents or activatable carboniferous material in liquid form or in soln., granulating or pressing the paste so formed and then heating to glowing. In the example, active C is mixed to a paste with sulfite lye and lime, pressed and heated.

Activated carbon. RUDOLF DEFRIS and ROBERT WÄLDER. U. S. 1,783,110, Nov. 25. See Fr. 666,647 (*C. A.* **24**, 1476).

Adsorbent decolorizing carbon ground to particles of about 2μ to 9μ size. JOHANNES VAN LOON. U. S. 1,782,493, Nov. 25.

Dissociating hydrocarbons such as acetylene for producing carbon black and hydrogen. JOSEF MACHTOLF (to Chr. Hostmann-Steinberg'sche Farbenfabriken G. m. b. H.). U. S. 1,782,540, Nov. 25. An app. is described in which a portion of the solid product is sepd. by settling while the remainder of the solid is blown through the dissocn. chamber with the gases for retreatment and further recovery.

Regenerating adsorption material such as active carbon or gels. VITALIS PANTENBURG (to American Lurgi Corp.). U. S. 1,784,536, Dec. 9. A column of the material is passed through a heat zone and an inert gas such as CO_2 or N is passed into the column near the end where the material enters the heat zone, and gaseous products are withdrawn from an intermediate portion of the column. App. is described.

Inorganic adsorbents. JOHN T. TRAVERS, CHARLES H. LEWIS and OLIVER M URBAIN (to Ohio Sanitary Engineering Corp.). U. S 1,783,396, Dec. 2. A tervalent metal salt of condensed orthosilicic acid, such as kaolinite, is mixed with a carbonaceous material such as sawdust and a soln. of an alkali metal silicate is added to the mixt., a dil. soln. of a strong acid such as H_2SO_4 is incorporated with the mass, followed by drying and ignition. The product is suitable for recovery of benzene or other solvent vapors.

Absorbent suitable for removing tobacco oils from smoke. CLARENCE W. ANDREWS. U. S. 1,784,566, Dec. 9. An absorbing material is prepd. by steaming vegetable material such as fibrous cotton and immersing it in hot caustic soda soln. and then boiling in water, drying and treating successively with boric acid and milk of magnesia

Use of furnace flue dusts as adsorbents. HEINRICH B. RÜDER (to Lurgi-Ges. fur Wärmetechnik m. b. H.). U. S. 1,784,543, Dec. 9. Flue dust from the combustion of lignite or other furnace flue dust is used as an adsorbent, preferably after classification into material of different grades and characteristics by fractional elec. pptn. or other suitable method, and suitably after a supplementary activation or extn. treatment.

Catalysts. ERNEST B. MILLER and GERALD C. CONNOLLY (to Silica Gel Corp.). U. S. 1,782,857, Nov. 25. A hydrogel such as that of silica is treated with a substance such as $Cu(NO_3)_2$ or NH_4 vanadate which is capable of conversion into a catalytic agent by heating; the impregnated hydrogel is converted into a hard porous gel, and the gel is heated to effect production of the catalytic agent.

Catalysts for hydrogenation reactions, etc. KARL MARX, HERMANN BEHNCKE and KARL BRODERSEN (to I. G. Farbenind. A.-G.). U. S. 1,783,662, Dec. 2. A soln. of a Co, Cu or Ni salt such as Ni sulfate or chloride is treated with H under at least 20 atm. pressure (suitably 30–40 atm and at a temp. of about 100°) in the presence of NH_3 or an

org. base or acid amide. Use of urea, pyridine, tri-ethanolamine, aniline and methylamine is mentioned, and a highly active catalyst may be obtained.

Catalytic zeolites. ALPHONS O. JAEGER and JOHANN A. BERTSCH (Jaeger to Selden Co.). U. S. 1,782,353, Nov. 18. A large no. of detailed examples and modifications of procedure are given for producing catalytic zeolites of different compns. and of their use in catalyzing various reactions, with or without various diluents, etc.

Condensation products of urea with formaldehyde, etc. I. G. FARBENIND. A.-G. Brit. 332,634, April 19, 1929. Solns. or dispersions obtained by condensing urea or its derivs. such as thiourea or methyl urea, with CH_2O or its polymers in the presence of an org. solvent, or the corresponding products obtainable from mono- or dimethylol-urea or -thiourea, are freed from org. solvents and volatile constituents by steam distn. The condensation is preferably effected in the presence of a small proportion of an acid-reacting substance such as HCl or oxalic acid, urea nitrate or $NaHSO_4$, or buffer substances or mixts. such as maintain a p_H of 6.0–5.2. Numerous examples and details of procedure and mixts. of the products with other substances for different purposes are described. Cf. *C. A.* **24**, 5118.

Condensation products from polyvinyl esters. I. G. FARBENIND. A.-G. (Arthur Voss, inventor). Ger. 506,148, Jan. 18, 1927. Resinous or oily products suitable as varnish bases, insulators, etc., are prepd. by heating polymerized vinyl esters of lower aliphatic acids with acids of high mol. wt. or their esters, *e. g.*, resin acids, stearic acid, oils and fats. Thus, polymerized vinyl acetate and colophony, heated gradually up to 250° under reduced pressure, yield a clear resin insol. in alkalies and EtOH but sol. in C_6H_6 and linseed oil. Other examples are given also.

Products from alginic acid suitable for making molded articles. LAURIE L. BURGESS (to Plastic, Inc.). U. S. 1,782,887, Nov. 25. Reaction is effected between alginic acid and a hydrocarbon material such as paraffin wax and the product is rendered plastic by addn. of an alkali such as NH_3 or NaOH and may be molded. Finely divided metals also may be added.

Adhesive. WILLY O. HERRMANN and WOLFRAM HAEHNEL (to Consortium für Elektrochemische Industrie). U. S. 1,784,008, Dec. 9. An adhesive which is suitable for joining various materials comprises alc.-sol. polymerized vinyl acetate and a softening agent such as isobutyl phthalate and solvent such as MeOH. Use of polymerized vinyl butyrate is also described. Cf. *C. A.* **24**, 1477.

Soft rubber-like composition. EFFIE H. MOSS. U. S. 1,784,070, Dec. 9. A compn. suitable for use in sealing joints is formed from linseed oil 2 teaspoonfuls, lime 1 teaspoonful, water 1.5 oz., isinglass 1 teaspoonful, soap soln. 1 teaspoonful, tincture of benzoin 5 drops, grease 1/4 teaspoonful and mercury 1 drop.

Mica tubes and sheets. ARTHUR LLOYD (to Bakelite, Ltd.). U. S. 1,784,737, Dec. 9. Mica is used with a binder comprising a condensation product of a phenol, a urea and an aldehyde.

Artificial gems. I. G. FARBENIND. A.-G. Ger. 506,146, Aug. 27, 1927. Artificial gems having a high refractive index and small dispersion are prepd. by fusing a mixt. of 1 mol. of MgO with 2–3.5 mols. of Al_2O_3 in app. of the kind customarily used in the art. The precautions necessary to obtain optically homogeneous products are referred to. Examples are given.

Magnetic cores. KARL EISENMANN and FRIEDRICH BERGMANN (to I. G. Farbenind. A.-G.). U. S. 1,783,560, Dec. 2. See Brit. 320,016 (*C. A.* **24**, 2847). U. S. 1,783,561. See Brit. 319,854 (*C. A.* **24**, 2847).

Coloring slate granules. HARRY C. FISCHER (to Philip Carey Mfg. Co.). U. S. 1,782,648, Nov. 25. The slate is wet with a soln. of a dichromate such as $Na_2Cr_2O_7$ in the presence of a metallic salt such as $FeSO_4$ which will react with the dichromate to form a jell, and the materials are then heated to dehydrate the jell and at least partially to convert it to oxides. U. S. 1,782,649 specifies the use of a dichromate together with Fe sulfate and a third compd. such as $CuSO_4$ which on heating of the materials decomposes with formation of a pigment. Cf. *C. A.* **24**, 4373.

Detergents. HENKEL & CIE. GES. Brit. 332,530, Feb. 5, 1929. A compn. suitable for cleaning Al and other metal household utensils comprises Na_3PO_4 and waterglass, with or without addn. of sand, soda, soap or other cleanser. Cf. *C. A.* **24**, 5119.

Washing and emulsifying agents. CARL A. AGTHE. Ger. 506,338, June 14, 1925. Sol pyrophosphates are used, alone or in conjunction with other washing, etc., agents not having bleaching properties.

Wetting, etc., agents. I. G. FARBENIND. A.-G. (Curt Schuster, inventor). Ger. 506,960, May 5, 1926. Addn. to 501,303 (*C. A.* **24**, 4906). Sulfonic acids (or their

salts) from halogenated, non-alkylated aromatic hydrocarbons are used as wetting or emulsifying agents, or *soap substitutes*. Examples are given.

Projection screen. DAVID F. NEWMAN (to Trans-Lux Daylight Picture Screen Corp.). U. S. 1,783,973, Dec. 9. A base such as cloth, paper or glass is provided with a coating formed from latex together with a diffuser such as casein, ZnO, Ca tungstate, NH_4 fluosilicate or LiF.

Metal sound records. F. H. SANBORN. Brit. 332,617, Jan. 23, 1929. Highly polished metal surfaces are used such as Al, Cu, brass or pewter with a lubricant such as paraffin or oil rubbed into the surface. Brit. 332,618 also relates to similar records.

Dialytic membranes. LEONARDO CERINI. Austrian 119,033, April 15, 1930. Vegetable fibrous material, *e. g.*, cotton or paper, which is to be used for making membranes for the osmotic purification of caustic alkali lyes, is treated with a soln. of an org. or inorg. salt of an alk. earth or earth metal, whereby it is converted into an alkali-insol. hydrocellulose. Treatment with a 10–12% soln. of $MgCl_2$ at 60–70° is suitable. The treatment may be preceded by treatment with concd. alkali soln. and followed by treatment with a resin soln.

Microphone diaphragms. H. E. HOLMAN and H. A. M. CLARK. Brit. 332,723, July 6, 1929. The surface of the diaphragm in immediate contact with the C granules forming the variable resistance is roughened by a coating of non-metallic granular material, the protuberances of which are united to each other and to the diaphragm. A mica or metal diaphragm may be coated with a film of cement carrying C or Carborundum granules, and the use of sand or ground glass also is mentioned.

Kiln suitable for burning limestone spalls. MARY E. SQUIRE. U. S. 1,783,632, Dec. 2.

Packing for plungers, rods and shafts. DAVID R. YARNALL and JOSEPH KILDARE (to Yarnall-Waring Co.). U. S. 1,783,762, Dec. 2. A molded packing ring comprising asbestos, graphite and rubber is held by an inner ring of Ni alloy.

Luting material. ROBERT B. MCCARTY (to Gulf Refining Co.). U. S. 1,782,932, Nov. 25. A luting suitable for use with app. handling free Cl comprises fine ground burnt clay 65° and 40° Bé. NaOH soln. 35%.

Poisons for warm-blooded animal pests. F. HOFFMANN-LAROCHE & CO., A.-G. Brit. 332,797, Sept. 19, 1928. Poison is prepd. contg. compds. such as the methylcarbamic ester of *m*-hydroxyphenyltrimethylammonium iodide stabilized by addn. of tartaric acid or HCl, etc. Mention is also made of the use of corresponding urethans, in which the I is replaced by some other salt-forming group.

Apparatus and system of operation for producing and delivering fire-extinguishing foam. WALTER PALMER (to Amdyco Corp.). U. S. 1,782,366, Nov. 18.

System for generating fire-extinguishing foam. DUNCAN W. PATTERSON (to American LaFrance and Foamite Corp.). U. S. 1,784,680, Dec. 9. Various details of app. and procedure are described.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

Glass masses. S. L. MANEVICH-ALMAZOV. *Keram. i Steklo* **6**, 350–2(1930).—M describes investigations made to det. the properties of glass masses prepd. from different kinds of clays, lime, dolomite, phosphorite and sand. The compns. of several batches are given and the properties of the masses obtained are tabulated. The thermal stability of the samples obtained is good and they have a low coeff. of expansion. Their chem. stability is higher than the stability of ordinary lime-alkali glass. M. V. K.

Testing safety glass. H. D. MURRAY AND D. A. SPENCER. *Ind. Chemist* **6**, 399–401(1930).—The process of mfg. safety glass is described briefly, and the properties a good safety glass should possess are discussed. Testing should be carried out under conditions most closely resembling those encountered in practice. A striker mechanism for delivering blows powerful enough to shatter the glass is described (2 cuts) and 4 photographs of different types of fracture are given. The tests recommended (together with the methods of carrying them out) are (1) fracturing test, (2) penetration test, (3) crushing test, (4) heating test, (5) coloration test, (6) edge-sealing test.

E. G. R. ARDAGH

Dimensional changes caused in glass by heating cycles. A. Q. TOOL, D. B. LLOYD AND G. E. MERRITT. *Bur. Standards J. Research* **5**, 627–46(1930).—Dimensional

changes produced by subjecting glasses to heating cycles approaching the annealing range are investigated. Expansion-temp. curves were obtained for a medium flint glass. Samples were tested which had previously received one or another of several different heat treatments. Heating cycles were employed in the tests which made it possible to det. the magnitude of the so-called "permanent" changes in length which are caused either by the annealing or the "disannealing" which may result from the heat treatment imposed on the glass by the heating cycle. The length and sp. vol. are decreased by annealing and increased by disannealing. These effects are related to certain ice-point shifts observed in thermometers, a discussion of which is included.
ALLEN S. SMITH

Observations of temperature of annealing chambers for hollow ware. R. D. CHANDORKAR AND K. R. RANGAIYENGAR. *J. Indian Ceram. Soc.* **2**, 98–103(1930).—Data are given of the observed temps. of the annealing chambers ordinarily used in the glass works. The coal consumption is also stated. Details of an exptl. chamber and data obtained are given. JOHN M. LADINO

Decolorization and melting investigations. SILBERT GUSS. *Sprechsaal* **63**, 812-7 (1930). C. H. LORIG

Electrical porcelain (GILLETT) **4.** Armenian pumice stone (OTAROV) **18.**

Apparatus for feeding mold charges of molten glass. MERTON A. STEELMAN (to Hartford-Empire Co.). U. S. 1,784,763, Dec. 9. Structural features.

Apparatus for forming molded glass articles. RICHARD LA FRANCE (to Owens-Illinois Glass Co.). U. S. 1,783,191, Dec. 2. Structural features.

Apparatus for forming molded glassware such as bottles. LEONARD D. SOUBIER (to Owens-Illinois Glass Co.). U. S. 1,783,201, Dec. 2. Structural features.

Glass-pot-filling apparatus. WM. E. BARNES (to Pittsburgh Plate Glass Co.). U. S. 1,783,459, Dec. 2. Structural features.

Apparatus for making blown glassware. R. F. HALL. Brit. 332,622, Jan. 28,1929. Structural features.

Heating molten glass by electric resistances, for sheet-glass manufacture. JOHN L. DRAKE (to Libbey-Owens-Ford Glass Co.). U. S. 1,781,917, Nov. 18. Structural and elec. features.

Apparatus for sheet-glass manufacture. WM. L. MONRO (to Window Glass Machine Co.). U. S. 1,782,972, Nov. 25. Structural features.

Tank furnace, rolls and electric heating system for sheet-glass manufacture. HARRY F. HITNER (to Pittsburgh Plate Glass Co.). U. S. 1,783,473, Dec. 2. Structural and electrical features.

Circular glass furnace with rotary sole. ARTHUR BRANCART. Ger. 506,468, Oct. 12, 1928.

Leer for annealing glassware. PERCY Q. WILLIAMS (to Owens-Illinois Glass Co.). U. S. 1,783,208, Dec. 2.

Method and plant for cooling glass objects. FRITZ ECKERT. Ger. 506,386, Jan. 18, 1928.

Preventing weathering, clouding and tarnishing of glass surfaces. KIYOSHI KAMITA (to Asahi Glass Co., Ltd.). U. S. 1,782,169, Nov. 18. The surface of glass is treated with an acid gas at a temp. between about 150° to 315°, the gas used being a mixt. of gas ordinarily present in the leer and added gas such as SO_2, SO_3, H_2S, Se oxide, Cl, HCl, Br, HNO_3 or CO_2.

Apparatus for manufacture of "splinterless" glass comprising united sheets of glass and cellulose acetate or similar material. JOHN JEFFRAY. U. S. 1,782,852, Nov. 25.

Uniting cellulose ester and glass sheets. TRIPLEX SAFETY GLASS CO., LTD., and J. WILSON. Brit. 332,551, April 20, 1929. The glass is coated with gelatin with or without an enamel or cement and the sheets are brought together while immersed in an inert or non-solvent liquid of high b. p. with or without an admixt. of a solvent or plasticizer of high b. p. and the sheets are united by heat and pressure. Various details of temps. and liquids used are given.

Apparatus for uniting sheets of glass with an intervening sheet of "pyralin" or the like under pressure in a rubber bag. JAMES H. SHERTS (to Duplate Corp.). U. S. 1,783,985, Dec. 9. Structural features.

Impregnating bricks with thermoplastic materials such as bitumen. ANDREAS J. M. STOFFELS and HERMAN T. VAN DER WISSEL. U. S. 1,784,164, Dec. 9. Bricks or the like are first preheated and the different sides of the preheated material are

then impregnated to a different extent under pressure by cooling at those sides of the material where a less intensive impregnation is desired. App. is described.

Ceramic products. VICTOR M. GOLDSCHMIDT. U. S. 1,782,295, Nov. 18. In the production of products such as strong refractory materials, in which mixts. of Mg hydrosilicates other than talc are used with substances rich in Mg such as magnesite, the mixts. are heated to temps. at which Mg orthosilicate is formed without fusion (suitably about 1300°).

Firing ceramic ware. A. S. WATTS. Brit. 332,692, June 7, 1929. Ceramic products such as dental porcelain is fired in a continuous kiln and successively subjected to biscuiting, vitrifying, glazing and annealing, with a temp. drop after either or both the biscuiting and vitrifying operations and an abrupt temp. drop after the glazing and preceding the annealing operation. App. is described.

Pottery mold. WM. J. MILLER. U. S. 1,784,373, Dec. 9.

Porcelain insulators. DAVIDGE H. ROWLAND (to Locke Insulator Corp.). U. S. 1,784,392, Dec. 9. In the manuf. of porcelain insulators of the type having a portion provided with granular material such as fired crushed porcelain united thereto, glazing liquid is applied to this portion to coat the granular material.

Emery wheels. L. BRUNELLI, G. CARRA and F. SOFIA. Brit. 332,524, Feb. 21, 1929. See Fr. 669,965 (*C. A.* **24**, 1952).

Grinding wheels of bonded abrasive materials. THURE LARSSON (to Norton Co.). U. S. 1,783,727–8–9, Dec. 2. Structural features.

Bituminous dispersion. RICHARD W. LEWIS. U. S. 1,783,365, Dec. 2. Portland cement is used as dispersing agent in prepg. aq. bituminous dispersions suitable for use as coating or bonding agents, etc. U. S. 1,783,366 relates to dispersions prepd. by mixing bitumen, $Al(OH)_3$ paste, clay and water.

Opacifier for enamels THOMAS H. MCKEOWN (to Roessler & Hasslacher Chem Co.). U. S. 1,783,738, Dec. 2. A mixt. of Na antimonate 3 and Sn oxide 1 part is used in the production of a white enamel. U. S. 1,783,739 and U. S. 1,783,740 also give formulas of enamels contg. this opacifier together also with other ingredients such as feldspar, flint, borax, H_3BO_3, $NaNO_3$, cryolite, fluorspar, $BaCO_3$, Pb_3O_4, whiting and ZnO, in specified proportions.

Coating metals, etc., with enamel, glass, etc. AUGUST PAHL. Ger. 468,556, Feb. 26, 1925. The article to be coated is heated by a blowpipe flame, and the powd. coating material is blown on to the article and fused *in situ*. The blast for the coating material may be sep. from that for the flame. App. is shown.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Petrographic investigation of alumina cement. KATSUZO KOYANAGI. *J. Soc. Chem. Ind., Japan* **33**, Suppl. binding 352–8(1930)(in German).—The main component of $CaO \cdot xAl_2O_3$ cement crystallizes in the form of a spherulite, $3CaO \cdot 2Al_2O_3$ m. about 1300°, which is in addn. to the Ca aluminates proposed by Rankin. E. M. S

A review of revised A. S. T. M. specifications for paving brick. F. H. JACKSON *Am. City* **42**, 139(1930).—The rattler test is discussed. C. H. BADGER

Armenian pumice stone (OTAROV) **18.** Basic open-hearth slag as a valuable blast furnace material (HORAK) **9.** Zn meta-arsenite (TAYLOR) **18.** Asaphus limestone (Ordovician) in the drill hole of Lagedi (ORVIKU) **8.** Setting and hardening of cements for stopping oil wells (KEMMER, BALAN) **22.** Phosphate fertilizers [cement production from residue] (Brit. pat. 332,639) **15.** H (Ger. pat. 506,041) **18.**

Portland cement. JOHN A. MILLER and EDMUND P. NEWHARD. U. S. 1,784,462, Dec. 9. A mixt. of raw materials for making portland cement comprising at least two ingredients of different hardness such as limestone and shale is subjected to dry grinding comprising a preliminary reduction operation, a grinding into relatively fine and relatively coarse particles, and a sep. fine grinding of the two sep. portions of the material. An arrangement of app. is described.

Preparing uniform mixtures of materials such as cement and asbestos. JOHN C. MACILDOWIE (to Asbestos Wood & Shingle Co.). U. S. 1,781,728, Nov. 18. App. and various mech. details are described.

Accelerating hardening of cement. WALTER KIRCHNER (to Chemische Fabrik

Grünau, Landshoff & Meyer A.-G.). U. S. 1,782,471, Nov. 25. A mixt. of substantially equal quantities of $CaCl_2$ and $AlCl_3$ is added, as an accelerator, while working portland cement mixts.

Rotary cement-burning kiln. AXEL V. JENSEN (to F. L. Smidth & Co.). U. S. 1,781,845, Nov. 18. Structural features.

Concrete, etc. R. CROSS. Brit. 332,604, Feb. 25, 1929. To so-called "gelatinizing clays" (defined as including bentonite, "chemically treated clays," natural and artificial hydrated silicic acids, and pptd. hydrates such as $Al(OH)_3$) there are added a substantially smaller quantity of materials of approx. the same p_H in water as an equal wt. of MgO, such as portland cement, magnesia cement, furnace slag, alk. earth phosphates or silicates, aluminates or MgO itself. Oil 10–15% also may be added and the mixt. thus prepd. added to portland cement to form *waterproof concrete*. A paint may be made of the untreated clay and cement, with or without oils (drying or non-drying), asphalt, pigments, etc. Fibrous materials may be added for making roofing, etc., and road compns., mortars, etc., are described and formulas given.

Bituminous emulsions for use on roads, etc. R. LICHTENSTERN. Brit. 332,591, April 22, 1929. Material such as petroleum asphalt is mixed with about 1–3% (or more, up to 20–25%) of Trinidad or Bermuda asphalt or Montan wax and a hot soln. of caustic alkali; the products are miscible with water, and break down less rapidly on admixture with road-making or building materials.

Material for conduit construction. JOHN F. MAKOWSKI (to Fireproof Wall Co.). U. S. 1,783,178, Dec. 2. Conduits such as those for underground elec. cables are formed from a mixt. of soapstone 2, clay 1.5 and cement 1 part.

Building blocks. IRVING J. SMITH. U. S. 1,782,748, Nov. 25. A hardened product is formed from a mixt. of water-satd. cinders of uniform size, an inert filler the main ingredient of which is $CaCO_3$ together with cement and water.

Porous building material. ALBIN V. CARLSON. U. S. 1,782,460, Nov. 25. A "foundation mass," *e. g.*, santorin earth, puzzuolana, trass or pumice, contg. at least one of the compns. Fe_2O_3, Al_2O_3 and SiO_2, is mixed with sufficient unslaked lime to produce a porosity on slaking, with small pores throughout the entire mass, and other substances such as NaOH and Zn, Fe or Al or a metal carbide are added to facilitate gas generation and pore formation in reaction with the lime and water.

Porous bricks, etc. HANNS WEEH. Austrian 119,045, April 15, 1930. In the manuf. of porous bricks, etc., from a mixt. of cement and Al, with or without CaO, sand, etc., better results are obtained by including kieselguhr in the mixt.

Artificial marble. ALBERT SOMMERFELD. Ger. 506,116, July 24, 1925. Sep. portions of cement or the like are impregnated with solns. of different mineral salts that react to form colored compds. and the portions are coarsely mixed while damp and pressed.

Apparatus for coating roofing felt shingles, etc. CHESTER R. MACDONALD (to Patent and Licensing Corp.). U. S. 1,783,575, Dec. 2.

Treating roofing material such as felt shingles with asphalt, etc. CHESTER R. MACDONALD (to Patent and Licensing Corp.). U. S. 1,783,849–50, Dec. 2. App. and various details of operation are described.

Kiln suitable for drying lumber. JAMES A. WORDEN. U. S. 1,783,030, Nov. 25.

Apparatus for drying and conditioning lumber, etc., in circulated air currents of regulated humidity. GORDON D. HARRIS (to Industrial Dryer Corp.). U. S. 1,784,727, Dec. 9. Structural features.

Coloring wood. ADOLF SCHWARZENBERG. Austrian 119,047, April 15, 1930. See Fr. 666,961 (*C. A.* **24**, 1197).

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

Fuel problems at Second World Power Conference. A. SANDER. *Brennstoff-Chem.* 11, 340–2, 360–1, 375–8, 398–9(1930). F. W. JUNG

Determination of moisture in solid fuels. M. DOLCH. *Brennstoff-Chem.* **11**, 429–32, 478(1930).—Errors inherent in present standard and other methods are discussed. The cryohydric method proposed depends upon the temp. rise resulting when abs. alc. which has been boiled with the material to be tested is mixed with suitable liquid hydrocarbon. From 10 to 20 g., depending upon the H_2O content, of < 3 mm. mesh is boiled with 100 ± 0.1 g. abs. alc. for 5 min. After cooling, the alc. is

quickly poured through a dry folded filter, the first of the filtrate discarded, and 20.0 cc. added to an equal quantity of hydrocarbon in a special mixing tube fitted with a thermometer. The temp. rise of the mixt. gives the H_2O content by employing a curve previously plotted with measured amts. of H_2O. The results obtained with the cryohydric method for representative coals and cokes on comparison with other methods show the latter vary greatly from the true moisture content. The use of the method for moisture detn. of tar, etc., is shown. F. W. JUNG

The sulfuric acid test for motor benzene. F. KNÖTTNER. *Brennstoff-Chem.* **11**, 432–5(1930); cf. *C. A.* **24**, 4913.—Tabulated data as sp. gr., distn. range, H_2SO_4 test, Br no. and evapn. residue are given for C_6H_6, toluene, xylene and a large no. of motor fuels to show the possibility of substituting an evapn. test for the H_2SO_4 test. A method of evapn. through heating in a current of air has been developed. A 20 mg. residue limit for 200 cc. is suggested. F. W. JUNG

Heating values of various woods from European Russia. L. A. MARZHETZKII. *Izvestiya Teplo-Tekh. Inst.* (*Trans. Thermo-Tech. Inst. Russia*) **1930**, No. 4, 65–77.—Heating values of woods preliminarily dried for 2.5 hrs. at 105° were detd. in a calorimeter bomb. They were for linden tree 5.075–5.096; for birch tree 4.822–4.831; for poplar tree 4.685–4.695; for pine tree 4.893–4.896 and for spruce-fir tree 5.001–5.300 calories. The analytical procedure, sampling and calcns. are given in detail. A. A. B.

Chemical and microscopical investigations of the coals from the Witbank and Ermelo coal fields. P. E. HALL. *J. Chem. Met. Mining Soc. S. Africa* **31**, 44–8(1930), cf. *C. A.* **24**, 4915, 5133, 5969.—Discussion. ALDEN H. EMERY

The hydrogenation of South African coal. P. N. LATEGAN. *J. Chem. Met. Mining Soc. S. Africa* **31**, 50–3(1930); cf. *C. A.* **24**, 2859–60, 5133.—Discussion. A. H. E.

Analytical characteristics of coals. W. FUCHS. *Brennstoff-Chem.* **11**, 332–4 (1930).—Analytical methods are discussed and grouped according to the aim of characterization: ultimate analysis for elements; proximate analysis for technically important constituents; decompn. analysis for detg. chem. combinations as bitumens, humic constituents, etc.; and at. groupings. The last are tabulated for analytical characteristics and methods of detn. F. W. JUNG

Apparatus for determining tendency of coal and other materials for spontaneous combustion. D. J. W. KREULEN. *Brennstoff-Chem.* **11**, 261–2(1930).—The app. of Hofer is described with detailed drawings whereby the material is heated in current of O_2 in a cylindrical Al block, the kindling temp. being obtained by a N_2 thermometer in the tested material. In testing coal, a sample 10–20 mesh per cm. is prepd. from the briquetted finely powd. coal and placed upon Cu gauze resting in a 20 mm. vertical boring in the block which is also fitted with a thermometer well and O_2 preheating passages. A microburner permits heating rates of 1°/min. and a flowmeter is used to maintain const O_2 flow. In order to eliminate misrepresentation from sieving, the coal used is briquetted from a finely powd. av. sample. In testing oils, graded pumice stone is used as absorbent. It is also possible to collect and analyze the gases evolved. F. W. J.

Apparatus for determining plastic range of bituminous coal. R. KATTWINKEL. *Brennstoff-Chem.* **11**, 329–30(1930).—App. and procedure are described. Powd. or briquetted coal in a transparent quartz tube is placed in an Al cylinder, having an observation slit and thermometer well, and is heated with a microburner rapidly to 250°, then 5°/min. The temp. at which bitumens decomp. is indicated when oils condense on the stopper and in the outlet tube. The softening point is indicated by the start of swelling and the solidification point by the end of swelling. The stopper is then removed and heating continued 10 min. at 520° to det. the weight of semi-coke. Results agree with those obtained by previous methods. Semi-coke yields are within 1–2% of those by the Fischer assay. Results are given for a dozen coals. F. W. JUNG

Investigation using Geipert [coal distillation] apparatus. F. SCHUSTER. *Brennstoff-Chem.* **11**, 471–3(1930).—By use of various German coals, comparisons are made with results obtained by other methods. Limits of duplicability in G.'s test are shown by examn. of results from duplicate operators and app. Gas vol., calorific value and compn., coke analysis and calorific value are compared with that obtained by the Münchener method and in coking practice. Conclusion: The fast heating rate in G.'s retort produces more heavy hydrocarbons than practice; the distn. time is longer in comparison; the final coke temp. is too high whereby coke is poor in H, and (S + N + O); and the vertical retort permits cracking of refluxing tar. F. W. JUNG

Mineral constituents of coal and their influence on ash determination. F. SCHUSTER. *Brennstoff-Chem.* **11**, 237–9(1930); cf. *C. A.* **24**, 4374.—Studies of the ash content and constituents of nine gas coals have been made; variations of CO_2 content are taken as indicating changes in ash compn. The actual ash alky. was less

than that for the CaO calcd. from the CO_2 content of each ash, the analyses showing that some CO_2 was combined with Fe. Muffle construction preventing contamination during ashing with the heating gases or the use of elec. heating in a H_2S-free atm. is recommended with CO_2 as well as S detns. in coal analysis. F. W. JUNG

Sulfate content of coal ash. F. SCHUSTER. *Brennstoff-Chem.* **11**, 262–3(1930); cf preceding abstract.—To explain previous findings, the original sulfate content of the coals has been detd. and compared with that obtained through ashing in an atm. freed from S compds. The greater part of the ash sulfate content was shown to come from the S compds. in the coal which were apparently catalytically oxidized to sulfate by other ash constituents. The sulfate formation increased with the carbonate content of the coal. A suggested formula for detg. the true ash content of coal from constituents: % true ash = % ash + % CO_2 + (% FeS_2 × 0.335) + % SO_3. In complete coke analysis, a total of > 100% is obtained, increasing with carbonate and Fe content of original coal, because of the oxidation of Fe^{++} to Fe^{+++} and to the sulfate. F. W. JUNG

Coal-tar pitch as binder for bituminous coal briquets. Briquet strength. A. SPILKER AND G. BORN. *Brennstoff-Chem.* **11**, 307–18(1930).—History and previous work upon briquetting of bituminous and brown coal are reviewed, the effects of various factors in binding, as H_2O content, etc., being discussed. By use of octagonal and rectangular briquets made under uniform conditions and dried to const. wt. the effects of coal particle size, mixts. of various sizes, and amt. of pitch binder upon breaking and tensile strength and cohesion have been detd. and are shown graphically. Normal variations in particle size produced changes in strength greater than did 25% variations in binder amt., the finer sizes producing the strongest briquets. With the fine sizes also, increase in pitch content from 6 to 8% produced enormous increases in cohesive strength as detd. by tumbler test. Increases in strength of 20% followed increasing fineness and uniformity of distribution of the ground pitch. Low-melting pitches gave greater cohesive but lower breaking and tensile strength. High-vacuum pitches were good binders. The term "Facherzahl" (Fz) or Diversion no. is introduced to indicate extent of variation from the av. in strength tests. F. W. JUNG

Dry cleaning of coal in England. KENELM C. APPLEYARD. *Am. Inst. Mining & Met. Eng. Tech. Publ.* No. **374**, 34 pp.(1930). E. H.

Comparisons of methods for determining the caking power of coal. G. AGDE AND A. WINTER. *Brennstoff-Chem.* **11**, 394–6(1930).—By use of progressive mixts. of a high volatile and an anthracite coal, the caking index has been detd. by the methods of Meurice-Kattwinkel, Meurice-Gabinsky and Marshall-Bird. Variations from averages are shown and results are compared graphically. Results from a single method are only comparative for similar coals and mixts. The Marshall-Bird test proved the most reliable. F. W. JUNG

Berginization of some coals and tars. N. A. OKLOV, V. V. TISHCHENKO AND N. D. LIKHACHEV. *Zhur. Prikladnoĭ Khim.* **3**, 699–719(1930).—Berginization expts. were carried out in a 3 l. bomb, provided with a pressure gage and an inserted Cu-constantan thermocouple, rotating at 30–50 revolutions per min. It was electrically heated first with a strong current to raise the temp. to a required height and later with a current just to keep this temp. const. Moscow Pobedinskii coal heated to 400–480° without a catalyst and at an original H_2 pressure of 50 to 90 atm. produced after 1–5 hrs. heating 0.36% gases, 8.32–19.7% oil and up to 78% solid substances. Bobrikovskii coal under similar conditions yielded in the presence of ZnO, Al_2O_3 or FeO catalysts 2.1–2.3% gases, 14–19% oil and 65.3–68.8% solid substances. Shchekinskii coal produced with or without catalysts ($NaHCO_3$) 2.64–2.92% gases and 12–21% oil. The Bobrikovskii distillate contained 23.75% gasoline. Under the above conditions Balkashit yielded 75–78% of an oil when hydrogenated with a kaolin catalyst. Barsas coal yielded 42% without catalyst; with NH_4 molybdate, 98 atm. cold H_2 pressure, 1½ hrs. heating at 435–440° it gave 37.2% oil; with the same catalyst, 96 atm. H_2 pressure, for 1½ hrs., at 440–450°, 43.2% oil; at 93 atm., 1 hr. 40 min. at 430–445°, 38%; at 115 atm., 1½ hrs. at 435–450° in the presence of CoO catalyst, 41%; at 120 atm., 1½ hrs. at 435–450° and NH_4 molybdate catalyst, 47% oil, the residue being an almost pure ash. Sugar charcoal with $ZnCl_2$ catalyst, 85 atm., 420–445°, 2 hrs. 20 min. yielded a condensate of 0.9803 sp. gr. The coal used in hydrogenation contained an av. of 35% ash and 5% H_2O. Bobrikovskii coal mixed with a berginized 200–300° fraction subjected to 240–270°, 90–100 atm. cold H pressure for 2 hrs.–3 hrs. 55 min. yielded 20% of oil in addn., while Shchekinskii coal mixed with anthracene oil under similar conditions yielded 23% of oil, leaving 68% ash and residues. Oil obtained from berginized Barsas coal was again hydrogenated, yielding up to 32.85% of a cut boiling below 150°, 30% at 150–230°, 10.7 at 230–300° and a residue intermingled with paraffin crystals. Gases

obtained in the berginization of Barsas and Pobedinskii coals contained 0.5 and 15% CO_2, 0.7 and 3.8% CO, 0.5 and 0.4% C_nH_{2n}, 51 and 85.5% H_2, 12.5 and 25.8% C_nH_{2n+2}, 0.3 and 4% N_2. The H_2O of hydrogenation contains NH_3. Impure phenols contg. S compds. were hydrogenated in the presence of a Mo catalyst pptd. on pumice stone. The reaction was more complete than with C. P. phenols, which indicates that S compds. present in the impure phenol have a catalytic action. The light oil obtained had, in both cases, a pleasant gasoline-like odor and was composed of 67% of cycloparaffins. Xylenol, *o*-cresol and hydroquinone were also hydrogenated in the presence of Mo catalyst. A great no. of tables and other data are given for which the original should be consulted. A. A. BOEHTLINGK

The determination of aromatic unsaturated and naphthene hydrocarbons in light oils and motor spirits. A. B. MANNING AND F. M. E. SHEPHERD. *Dept. Sci. Ind. Research, Fuel Research Tech. Paper* No. 28, 14 pp.(1930); cf. *C. A.* 23, 3802.—In an attempt to develop an improved method of analysis of light oils from coal carbonization small quantities of oil were vaporized with air and passed through a suitable reagent, the increase in weight of which was detd. It was found that 98% H_2SO_4 contg. 2–3% of Ag sulfate was an entirely satisfactory reagent for the detn. of aromatic hydrocarbons in mixts. contg. no unsatd. hydrocarbons. Where unsatd compds. are present the mixt. is first nitrated with nitrosulfuric acid. The unsatd compds. are converted to CO_2, water and products sol. in water or in aq. NaOH. The aromatic compds. are isolated and detd. as nitro derivs. The naphthene content of a light oil may be roughly detd. by the aniline point of the residual oil from which the unsatd. and aromatic hydrocarbons have been removed. Expts. on the catalytic dehydrogenation of naphthenes to aromatics followed by absorption with nitrosulfuric acid indicated that this is a more accurate method for the detn. of naphthenes. The methods used are described in detail. D. F. BROWN

Salts and esters of humic acids. W. FUCHS AND O. HORN. *Brennstoff-Chem.* 11, 372–5(1930).—K salts of various German humic and nitro-humic acids have been prepd. by treating the acids with alc. KOAc soln. as well as by sapon. of methylated humic acids with alc. KOH. Comparisons of the K content of the latter with the methoxyl ester content of the methyl deriv. were in satisfactory stoichiometrical agreement. The salt formation of the original non-methylated acids frequently bound more K than subsequent formation of carboxylates indicated, participation of phenolic hydroxy groups being believed responsible. Particulars in regard to constitution and reactions of humic and nitro-humic acids are also given. F. W. JUNG

Catalytic reduction and hydrogenation of phenols with hydrogen under pressure. H. TROPSCH, B. HLAVICA AND O. WEINSTEIN. *Brennstoff-Chem.* 11, 449–52(1930) cf. *C. A.* 20, 2063.—In the high-pressure reduction of cresols at 460–80° and pressures to 240 kg./sq. cm , MoS_3 has been found most efficient, giving a nearly complete reduction to hydrocarbons. The efficiency of $Ni(OH)_2$ is strongly affected by the presence of S. The phenols are reduced by a hydrogenation of the hydrocarbons formed more with Ni than with Mo catalysts. Cyclic alcs. are not produced. Of the large no. tried, $ZnCl_2$, $Al(OH)_3$, $(NH_4)_3VO_4$, $Cr(OH)_3$, UO_3, $Co(OH)_2$ and NiS were excellent catalysts; ZnO, basic Cu chromate, WO_3 and $Fe(OH)_3$ were of no account. Comparative exptl. data for the catalysts used are tabulated together with analytical data for the reaction products obtained. F. W. JUNG

Determination of phenols (acid oils) in gas- and low-temperature carbonization liquors. E. KRES. *Brennstoff-Chem.* 11, 369–71(1930).—Comparative results are given for several liquors. Previous methods, which are briefly discussed, are used and also one developed by K. The method is described in detail and consists of: removing the phenols by distg. from the filtered liquor to which has been added $CuSO_4$ soln. and dil H_2SO_4. The phenols are then detd. by bromination or colorimetrically. Modifications for various liquors are also given. F. W. JUNG

New developments in mechanical purification of coal gases. A. THAU. *Brennstoff-Chem.* 11, 416–8, 435–8, 455–9(1930).—Gas purification and methods are discussed. The processes of Smith, Bartling and Feld are described in detail with diagrams. Comparative operation data for the last method are given for NH_3 and C_6H_6 recovery as contrasted with that of one of the more common types of today. F. W. JUNG

Self-carbureting of industrial gases from brown coals. M. FREUND AND E. BECKER. *Brennstoff-Chem.* 11, 335–7(1930).—An app. is described with a diagram whereby brown coal producer tar and pitch are cracked by dropping through a vertical tube, filled with Fe filings, mounted in an elec. furnace. Analyses of the gas obtained at temps. 470–1200° indicated gasification of highest thermal efficiency occurred between 750° and

800°, being 37% for the pitch obtained by vacuum distn. of the tar and 48% for the tar. Pressure and raw material had less effect than cracking temp. F. W. J

Gases in Makat. F. A. TREBIN AND P. I. LUCHINSKII. *Neftyanoe Khozyaĭstvo.* 18, 789–92(1930).—The compn. of gases analyzed by the Hempel-Winkler method is by vol.:

A. A. BOEHTLINGK

Natural gas. V. A. SOKOLOV. *Neftyanoe Khozyaĭstvo.* **18,** 793–6(1930).—The compns. of natural gases from Surakhanui, Grozny and Dagestanskie Ogni are, resp., air 1.0, 1.0, 1.0; CO_2 18.2, —, 7.5; CH_4 77.5, 51.8, 89.0; C_2H_6 2.0, 10.7, 1.9; C_3H_8 0.8, 25.1, 0.6; C_4H_{10} 0.5, 8.8, 0.6; gases higher than butane from Grozny natural gas are 1.9. Burrell's, Shepperd-Porter's and Aston's gas analysis app. are described in detail. A. A. BOEHTLINGK

Possible utilization of natural gas for the production of chemical products. HAROLD M SMITH. Bur. Mines, *Information Circ.* **6388,** 5 pp.(1930); cf. *C. A.* **24,** 2270.—A chart shows the products obtainable from natural gas by oxidation, pyrolysis and chlorination and the uses of each. These products and (in parenthesis) the compds. derived therefrom are: oxidation—water gas, H_2, MeOH, acetone, formaldehyde (bakelite); pyrolysis—H_2 (NH_3), C_2H_4 (C_2H_5OH, $C_2H_3Cl_2$, $C_2H_2(OH)_2$), C_3H_6 (isopropyl alc.), C_4H_8 (secondary Bu alc.), anthracene (alizarin), naphthalene (indigo), $C_2H_2(CH_3CHO)$, butadiene (rubber), C_6H_6 (resorcinol), C_7H_8 (saccharin), xylene and C black; chlorination—CH_3Cl, CH_2Cl_2, $CHCl_3$ and CCl_4. ALDEN H. EMERY

Chemical application for methane from natural gas. A. A. CHEREPENNIKOV. *Neftyanoe Khozyaĭstvo* **18,** 796–9(1930).—A review of the literature comprising chlorination, oxidation, water-gas reaction, reaction with CO and CO_2, decompn. into C and H_2, prepn of higher hydrocarbons, prepn. of carbides and prepn. of HCN. A. A. B.

Problems of removing hydrogen sulfide from Turner Valley gas. F. R. STALEY. *Petroleum Eng.* **2,** No. 2, 67–8(1930).—Large quantities of natural gas are desulfurized by scrubbing with a soda soln. CHAS. WIRTH

Studies on the development of Dakota lignite. I. Aqueous tension of the moisture in lignite. IRVIN LAVINE AND A. W. GAUGER. *Ind. Eng. Chem.* **22,** 1226–31(1930).—A study of the desorption and adsorption of H_2O vapor by 3 N. D. lignites by the desiccator method has shown: (1) loss of moisture is accompanied by decrease in vapor pressure; (2) vapor-pressure lowering of these 3 lignites varies but little and is similar to that for wood; (3) in drying for storage there is little need to reduce H_2O below 16%; (4) marked hysteresis occurs; (5) increase of temp shifts the dehydration curve toward the region of lower H_2O content; (6) the sorption of H_2O by lignite is by surface adsorption and capillary condensation; (7) the abnormal vapor pressures and the hysteresis may be explained by the colloidal structure of the lignite; (8) the capillary radii vary from 56.73×10^{-7} cm. near satn. to 0.3×10^{-7} cm. near the dry condition; (9) the av. latent heat of vaporization (20° to 40°) is 609.1 cal. per g. **II. Sorption of water vapor by lignite, peat and wood.** MAURICE LARIAN, IRVIN LAVINE, C. A. MANN AND A. W. GAUGER. *Ibid* 1231–4.—A study of the desorption and adsorption of H_2O vapor by N. D. lignite, Minn. peat and birch wood by the desiccator method showed: (1) the shapes of the vapor pressure *vs.* moisture curves are similar for all; (2) the peat and wood will dry to a lower moisture content than lignite at any given vapor pressure; (3) hysteresis is present in all 3, but is greatest for lignite and least for birch; (4) 50% of the bound H_2O is held in capillaries < 7.4 mμ in the peat, 5.6 mμ in the birch wood, 3.7 mμ in the lignite and 1.8 mμ in German brown coal. ALDEN H. EMERY

Action of organic solvents on Wattenbach bright pitch-coal, with especial reference to tar yield. C. STAEMMLER. *Brennstoff-Chem.* **11,** 281–2(1930).—Bitumen extn. of the dried coal with various solvents gave: C_6H_6 for 10 hrs., 8.7%; aniline, 53.3%, tetralin for 2 hrs. 7 times, 36.3%; the part extd. by aniline was more easily decompd. than that by tetralin. Comparison of Fischer assay tar yields of the original coal (tar 22.50%) with coals incompletely extd., *i. e.*, 18.32% by tetralin, 20.37% by tetralin then aniline and 43.04% by aniline showed 16.32, 10.80 and 16.00% tar, resp. The tar from the extd. coal was thin and poor in paraffins. Complete removal of the aniline prior to assaying was impossible, 12.50% being recovered in the carbonization. The addn. of 33 and 50% tetralin to the coal before carbonization did not affect the tar

yield, nor did aniline, phenol or petroleum oil, although the last increased the gas yield some. Humic acid detns. on tetralin- and aniline-extd. coals showed 9.72 and 5.03% ash-free, resp., because of their soly. in aniline. Humic acids carbonized gave only traces of tar. A short list of the literature covered is appended. F. W. JUNG

Formation of benzine and tar from ethylene by heating at atmospheric pressure without catalysts. H. WATERMAN AND A. TULLENERS. *Brennstoff-Chem.* **11**, 337–40 (1930).—Light oil, tar, unsatd. compds. in gas and C yields obtained by passing C_2H_4 through a heated quartz tube were detd. for temps. of 600° to 900° and are shown graphically with the Br no. of the light oil. Analytical data are given for the tar, beginning to form at 650° with max. of 24% at 800°, and the light oil beginning at 600° with max. of 13% at 750°. The C formation began at 700° and was 58% at 900°. The Br no. fell from 123 at 650° to 0 at 900°, possibly because of the formation of aromatic compds. The app. is shown diagrammatically. F. W. JUNG

Cracking and destructive hydrogenation of peat tar. B. K. KLIMOV AND V. A. LANIN. *Zhur. Prikladnoĭ Khim.* **3**, 727–40(1930).—Destructive hydrogenation carried out in a stationary bomb was about 5 times longer than that in a rotating retort. Up to 30% of products boiling below 200° and 35% of coke were obtained when cracking low-temp. carbonization peat tar in a rotating autoclave. The amt. of H_2 admitted into the bomb while hydrogenating the above tar was insufficient for a complete hydrogenation; this resulted in the formation of coke even in the presence of Al_2O_3, $Al(OH)_3$, Cr_2O_3, Mn_2O_3, SnO_2 and CuO. ZnO, FeO and particularly NiO and CoO are better hydrogenation catalysts; in their presence H is consumed before cracking starts. Coke is not formed in the presence of NiO and CoO. A gasoline yield of 27% was attained when hydrogenating at 100 atm. and 450°. This yield decreased to 20% after acid-alkali treatment of the distillate. An increasd in temp. increased the yield of light products, gases and coke, which was also true for prolonged heating. One hundred and ninety-eight l. H_2 was required to hydrogenate one kg. of tar. A yield of 37% of a kerosene fraction was obtained through hydrogenation which contained 30% phenols 5.4% bases and 14% unsatd. compds. A repeated hydrogenation brings the gasoline yield up to 48%; after the usual acid-alkali treatment, the yield of gasoline (d. 0.760) is 35%. A. A. BOEHTLINGK

Alcohol fuels. E. W. STEINITZ. *Automobiltech. Z.* **33**, 707–8(1930).—A general discussion on alc.-gasoline fuel mixtures. A. A. BOEHTLINGK

Production of strong coke by addition of tar in low-temperature carbonization of brown coal. C. STAEMMLER. *Brennstoff-Chem.* **11**, 413–4(1930).—The comparisons of cokes obtained by the carbonization in the Fischer Al retort of 1:1 mixts. of coal and generator tar show that the oxidation of the tar with air, MnO_2 or PbO_2 being used as catalyst, produces a strong well-caked coke. Examn. of the oxidized tar itself failed to reveal significant alteration, nor did oxidation of a generator light-oil. Although the coke is improved, the cost is unjustified. F. W. JUNG

Determination of specific gravity and macro-pore volume of coke and other porous substances. G. STADNIKOV. *Brennstoff-Chem.* **11**, 330–1(1930).—Replacement of apparent sp. gr. methods is proposed by a method which permits calcn. of micro-pore vol. by difference from the sp. gr. obtained from the powd. material. Coke is impregnated with paraffin (m. 50°) by evacuating 5–6 hrs. at 100° and cooling under 1.5–2 atm. CO_2 pressure. A piece is cut therefrom, and weighed (P_2), the vol. (V) of which is detd. in a special pycnometer. Paraffin is then extd. with benzine (b. 70°), a Soxhlet app. being used; it is evapd. under diminished pressure and weighed (Q). The macro-pore vol. is detd. as vol. (V_1) of paraffin, from its wt. (Q) and sp. gr. The true sp. gr. of coke is obtained as $(P_2-Q)/(V-V_1)$. Results are given for a no. of cokes, semi-cokes from coals and various peats, pressed coke dust, and wood charcoal which show micro-pore vol. of gas and metallurgical coke as negligible but appreciable in semi-coke. F. W. JUNG

Determination of "lump-density" of coke by surface paraffining. F. HOFFMANN *Brennstoff-Chem.* **11**, 297–9(1930).—True and apparent sp.gr. and the sources of error in the past and present methods are discussed. The proposed new method consists of: immersing weighed (E) pieces of coke in a paraffin bath at 125°, cooling the bath to 75°, then removing the coke, draining and weighing (F), a thin coating some mm. in depth being obtained; detg. the weight (G) of a 2-l. beaker, contg. an alc.-H_2O mixt. of sp. gr. (D), in which the coke is immersed, and fitted with immersing weights and a needle-point level indicator. The weight of the beaker, etc., without the coke, filled to the leveling point, is taken as (C). The sp. gr. (S) then = $(E \times D)/(C + F - G)$; it can be detd. to within ±0.1–0.2% with a few pieces totalling less then 0.5 kg. F. W. J.

Recovery of phenol from coke-oven gas liquor in relation to the best-known proc-

esses of by-product recovery. H. WIEGMANN. *Brennstoff-Chem.* **11**, 285–8, 304–6 (1930).—Schematic diagrams are given to indicate the incorporation of phenol recovery units in direct, semi-direct and indirect by-product recovery systems. Flow capacities are given for various installations to show possible recoveries. F. W. JUNG

Conversion of methane in coke-oven gas into acetylene by electrical discharge. K. PETERS AND A. PRANSCHKE. *Brennstoff-Chem.* **11**, 239–47(1930); cf. *C. A.* **23**, 4326.—The effects of rate of gas flow, pressure, tube charge and design, c. d., electrode design and position, and CH_4 concn. in gas used, upon C_2H_2 production under diminished pressure are investigated, curves being given for the effects of the variables upon the side reactions. The energy required for lab.-scale conversion in the reaction $2CH_4 \longrightarrow C_2H_2 + 3\ H_2$ has been reduced by improvements from 31 to 12 kw. hrs. per cu. m. C_2H_2, the efficiency of the elec. discharge being 38%. In addn., the exhausting pump required 2–3 kw. hrs. At 12 kw. hrs. input the gas rate was 100 l. per hr. and produced 5% C_2H_4, 9% being produced at an input of 44 kw. hrs., both using gas contg. 25% CH_4. With gas contg. > 50% CH_4, the C_2H_4 produced enters into further syntheses.

F. W. JUNG

Beneficial action of brown coal upon development of cultivated plants (KISSEL) **15**. Determination of C and H (STANSFIELD, SUTHERLAND) **1**. Origin of coal according to the present position of chemical investigation (FUCHS) **8**. Electric welding in carbonization plants and gas works (KÜRSCHNER) **9**. H (U. S. pat. 1,781,935) **18**. Alarm device for operating a signal on the escape of poisonous or explosive gases such as illuminating gas (U. S. pat. 1,783,974) **1**. Use of furnace flue dusts as adsorbents (U. S. pat. 1,784,543) **18**. Apparatus for degasifying liquids, particularly liquid fuels (Ger. pat. 506,040) **1**.

Hydrocarbon motor fuel. BENJAMIN FIXMAN. U. S. 1,781,872, Nov. 18. A raw heavy mineral oil is heated to conversion temp. under pressure and the oil and its conversion products are brought into intimate contact with a separately heated recycle oil, and the resulting hydrocarbon mixt. is released at a reduced pressure which will enable liquid components of the mixt. to vaporize; C is removed from the vapor by electromagnetic treatment, and hydrocarbons of the desired character for motor fuel are sepd. from those requiring recycling. App. is described.

Dust-fuel furnace burner. STEITZ & CO. G. M. B. H. Ger. 504,546, Mar. 8, 1927.

Distilling solid carbonaceous materials. FREDERICK T. SNYDER. U. S. 1,781,934, Nov. 18. An "autothermic" retort is fed with material such as oil shale, coal, wood waste or garbage and distn. is effected by contact with hot non-oxidizing gas. The solid residue from the distn. is burned in the base of the retort to supply this non-oxidizing gas and the heat required for distn. and the vapors evolved are fractionally condensed and the heavier fractions are injected at a point above the zone of combustion into the solid material undergoing distn., to act as part of a cooling fluid and to undergo cracking and distn.; uncondensed gases are heated and are injected at a point above the point of injection of the heavier condensates. App. is described.

Distilling carbonaceous material such as wood, lignite, coal, shale, etc. HENRY L. DOHERTY. U. S. 1,781,871, Nov. 18. The fuel is passed downwardly in a column through a shaft retort counter-current to a hot gas which does not support combustion, and volatilized products and gases may be removed from any portion selectively at the upper portion of the column to effect uniform distribution of the hot gas over the cross section of the fuel column. App. is described.

Fuel briquets. JAMES S. FORD and FREDERICK MURRAY. U. S. 1,784,665, Dec. 9. See Brit 329,437 (*C. A.* **24**, 5466).

Fuel briquets from wood charcoal. C. DEMOULIN. Brit. 332,815, Sept. 23, 1929. Wood charcoal is used with a binder of wood-tar pitch emulsified with a heated alk. soln. such as Na_2CO_3. Various details of manuf. are described.

Continuous vertical oven for drying and baking briquets. THEODORE NAGEL. U. S. 1,782,244, Nov. 18. Structural features.

Mechanical device for regulating combustion according to the composition of the combustion gases. SIEMENS-SCHUCKERTWERKE A.-G. (Karl Eisenzapf, inventor). Ger. 506,075, Feb. 28, 1926.

Apparatus for carbonizing coal with use of a saline heating bath. JOHN MITCHELL (to Charcolite Corp.). U. S. 1,784,676, Dec. 9. Structural features.

Tubular retort with a helical internal rotor, for carbonizing coal. OTTO H. HERTEL (to Old Ben Coal Corp.). U. S. 1,783,190, Dec. 2. The retort is externally heated in several sep. zones, and the rotor is provided with internal compartments for heating (also in zones and suitably by use of burners within the rotor). Cf. *C. A.* **24**, 4920.

Preparing pulverized coal for use as fuel. WALTER RUNGE and EDWIN A. PACKARD (to International Coal Carbonization Co.). U. S. 1,783,982, Dec. 9. Pulverized coal is subjected to a preliminary heat treatment in an oxidizing atm. under conditions to drive off only a small percentage of the hydrocarbon volatile constituents but such that the treated coal particles lose their sharp edges and are given a smooth and rounded surface and also slightly increased in size, and the material is then carbonized while suspended in a gaseous medium substantially inert with respect to the coal and with a temp. in the carbonizing zone sufficient to effect a low-temp. carbonization and drive off a substantial part of the hydrocarbon volatile content of the coal and produce a semi-coke with particles mainly of hollow spheroidal form, and the semi-coke is withdrawn and crushed. App. is described. U. S. 1,783,983 (WALTER RUNGE) relates to a semi-coke produced in a generally similar manner, and also describes app.

Dehydrating moist solid fuels such as raw brown coal. HANS A. VON STADEN and ANTON HOEHN (to I. G. Farbenind. A.-G.). U. S. 1,783,757, Dec. 2. A mixt. of raw brown coal and tar is heated to about 150° under a pressure of about 5 atm. and liquid water is sepd.

Low-temperature distillation of lignite. KOHLENVEREDLUNG A.-G. Ger. 506,126, Mar. 6, 1926. In the low-temp. distn. of loose dried lignite in vertical, indirectly heated retorts having inclined guiding surfaces, the tendency of the lignite to overshoot or overflow into the oven openings is counteracted by removing fine dust from the charge before or during its introduction into the retort

Apparatus for generating and superheating steam. HANS GLEICHMANN (to Siemens-Schuckertwerke Ges. m. b. H.). U. S. 1,784,426, Dec. 9.

Tubular steam generator and superheater. CHARLES U. SAVOYE (to Babcock & Wilcox Co.). U. S. 1,782,585, Nov. 25. Structural features.

Plant for generation of high-pressure superheated steam. FRITZ FLATT (to Akt.-Ges. der Maschinenfabriken Escher Wyss & Cie.). U. S. 1,781,836, Nov. 18. Structural features.

Apparatus suitable for steam generation or other heat-exchange operations. WALTER D. LA MONT and ALFRED F. ERNST (to La Mont Corp.). U. S. 1,783,724, Dec. 2. Structural features.

Tube and header heat-transfer apparatus suitable for use as a steam generator. EDWIN W. JONES (to Babcock & Wilcox Co.). U. S. 1,782,574, Nov. 25. Structural features.

Apparatus for flushing out scale from jackets of internal-combustion engines by use of reagents such as sodium phosphate. WALTER N. MOORE (to Three-M Mfg Co.). U. S. 1,783,478, Dec. 2. Structural features.

Absorption of ammonia and hydrogen sulfide. I. G. FARBENIND. A.-G. (Christian J. Hansen, inventor). Ger. 504,640, Jan. 8, 1926. NH_3 and H_2S are absorbed from gas mixts. by passage through a soln. contg. $(NH_4)_2SO_3$ and NH_4HSO_3, the mol. proportions of NH_3 and SO_2 being so arranged that the NH_3 and SO_2 tension of the soln is at about its lowest value.

Removing sulfur compounds from gases such as coal, water or producer gases. GUSTAV WIETZEL, JOSEF JANNEK and FRITZ FRIED (to I. G. Farbenind. A.-G.). U. S. 1,782,590, Nov. 25. The gas, together with sufficient O-contg. gas such as air to effect oxidation of the S compds. to O compds. of S, is passed over an active catalyst comprising a metal other than an alkali metal and a metalloid from groups 5 and 6 of the periodic system other than O, *e. g.*, a granular alloy of Fe 67, P 22 and Si 11% at a temp. which may be about 400°, and the S oxides formed are combined with NH_3 proportioned to form the corresponding NH_4 salt and the latter is sepd. Active charcoal also may be used as catalyst at 260°.

Desulfurizing gases. I. G. FARBENIND. A.-G. (Theodor Hoffmann and Fritz Overdick, inventors). Ger. 506,043, May 28, 1929. In desulfurizing gases by washing in a tower with a liquid that reacts with H_2S and liberates S, the sepn. of S from the suspension is facilitated by so collecting the liquid that the small quantities of gas occluded by the S are not sepd. Suitably, the flow of the suspension is gently arrested by inclined surfaces arranged at the foot of the tower, and the suspension is led to a sump, wherein the S collects on the surface. App. is shown.

Desulfurizing hot gases. ERICH WILL. Ger. 504,548, May 16, 1923. The gases are passed over basic minerals at high temps. in a regenerative furnace. A layer of

magnesite may be arranged between the basic minerals and the chamber lining. The chamber may be lined with limestone at the 700–1100° zone.

Gasifying fuels by heating in a fused salt bath. THEODOR LICHTENBERGER, LUDWIG KAISER and FRANZ MEYER. Ger. 493,475, April 17, 1927.

Treating wash waters of fuel distillation gases. WALTER KNOTHE. Ger. 506,021, July 14, 1929. A cyclic process is described for the treatment of water used in washing gases from the low-temp. distn. of fuels, particularly lignite. The water is freed from phenols by filtering through lignite ash, then treated with gases contg. CO_2, to remove $Ca(OH)_2$ and fix free NH_3, clarified, and then treated with the decarbonated gases after the latter have been passed in counter current to the water in the dephenolizing stage.

Fuel gas. KARL KOLLER. Austrian 119,040, April 15, 1930. In the method in which a producer is fed with a cooled mixt. of air and flue gases satd. with water vapor, the temp. at which the mixt. is satd. is regulated, so as to maintain a const. H content in the gas produced. Thus, the satn. may be effected by passing the mixt. of air and flue gases in counter current to warm water from the cooling jacket of the producer.

Water gas. THOMAS W. STONE (to Western Gas Construction Co.). U. S. 1,784,765, Dec. 9. The fuel bed of a generator is blasted with air to incandescence and the resulting air-blast gases are passed successively in sep. parallel streams through a single shell carburetor and a single shell superheater in which the air-blast gases are burned; the air blast is shut off and steam is passed successively through the superheater, carburetor and incandescent fuel in the generator, and the water gas generated is passed back through the carburetor and superheater to a gas receiver; the steam flow is then reversed to generate water gas before again bringing the fuel bed to incandescence and the water gas formed is similarly passed through the carburetor and superheater. App. is described.

Liquid volatile hydrocarbons from natural gas. SAMUEL C. CARNEY (to Shell Petroleum Corp.). U. S. reissue 17,898, Dec. 9. See original pat. No. 1,768,827 (*C. A.* 24, 4625).

Gas generator and burner suitable for utilizing liquid fuels. EDMUND A. GARRETT (one-half to Francis C. Schwab). U. S. 1,783,564, Dec. 2. Structural features.

Gas generator or producer. ERNST SCHUMACHER. U. S. 1,781,765, Nov. 18. Structural details.

Gas producer (with a rotary fuel shell and rotary ash pan). ANSON K. BRADLEY (to Morgan Construction Co.). U. S. 1,782,677, Nov. 25.

Valve-control system for gas producers. BAMAG-MEGUIN A.-G. Brit. 332,783, Oct. 27, 1928. Structural features.

Waterless gas holder. FREDERICK H. WAGNER (to Bartlett Hayward Co.). U. S. 1,782,861, Nov. 25.

Waterless gas holder. FREDERICK H. WAGNER (to Bartlett Hayward Co.). U. S. 1,782,949, Nov. 25.

Combustible gas and coke. HARRY F. SMITH (to Gas Research Co.). U. S. 1,781,766, Nov. 18. A continuous charge of material such as coal is maintained within a retort, and the outer zone of the charge of ignited material is blasted with air to incandescence to generate heat for raising the temp. of the contiguous central zone of material to drive off volatile constituents from it; the central zone is concomitantly blasted with steam. App. is described. U. S. 1,781,767 relates to a gas-producer construction, a portion of the producer being surrounded by a water boiler for generating steam for the gas-producing operation.

Gas or coke-oven wall. FRITZ TOTZEK. U. S. 1,782,638, Nov. 25.

Coking-retort oven. JOSEPH BECKER (to Koppers Co.). U. S. 1,784,414, Dec. 9.

Device for charging coke ovens with pressed coal. HEINRICH KOPPERS A.-G. Ger. 506,124, June 23, 1928.

Horizontal regenerative chamber oven. KOKSOFENBAU UND GASVERWERTUNG A.-G. Ger. 489,345, April 13, 1924.
